Minimum Hardware Requirements and Recommendations for Tableau Server	125
Minimum installation hardware requirements	126
Minimum production hardware recommendations	127
Determining Computer Hardware	130
Manually determining the number of cores on your computer	131
Install TSM	132
Prerequisites	133
Use the TSM web interface	133
Running Setup	133
Use the TSM CLI	137
Install Tableau Server	137
Configure Tableau Server for a forward proxy	138
Next step	138
Activate and Register Tableau Server	138
Prerequisite	139
Use the TSM web interface	139
Use the TSM CLI	143
Configure for forward proxy	143
Activate Tableau Server	143

Register Tableau Server	143
Next step	145
Activate Tableau Server Using the Authorization-To-Run (ATR) Service	145
How Tableau Server ATR works	145
ATR Duration	146
Set or change the Server ATR duration	147
Move a Server ATR product key to another Tableau Server	148
Deactivate a product key for reuse on another Tableau Server	148
Deactivate a product key in version 2021.4 and later	148
Deactivate a product key in version 2021.3 and earlier	148
Activate Tableau Server Offline	149
Offline activation and login-based license management (LBLM)	150
Offline activation overview	150
Offline activation file name changes	151
Use the TSM web interface	151
Use the TSM CLI	154
Step 1. Log in to Tableau Services Manager	154
What if I can't log in?	154
Step 2. Generate an offline activation request file	154
Step 3. Upload the offline activation request to the Tableau activation web-site	155
Step 4. Initialize or activate your license	155
Configure Product Key Operations with Forward Proxy	156

Before you begin	156
Step 1: Verify proxy configuration	157
Step 2: Temporarily change log on account for Tableau Server Administrative Controller service	158
Step 3: Activate, refresh, or deactivate Tableau product keys	158
Step 4: Revert the log on account back to Network Service	158
Configure Initial Node Settings	159
Prerequisite	159
Use the TSM web interface	159
Identity store settings	161
Run As service account	162
Gateway port	163
Product usage data	163
Sample workbook installation	164
Initializing install	164
Use the TSM CLI	165
Configure identity store settings	165
Configure gateway settings (optional)	166
Configure product usage data (optional)	166
Configure sample workbook installation (optional)	166
Apply pending configuration changes	167
Verify LDAP configuration (Optional)	167
Initialize and start Tableau Server	168

Next Step	168
Configuration File Example	168
Entities vs keys	169
Server Usage Data	170
Disable Usage Data Sharing	171
Disabling the sharing of usage data at install	171
Disabling the sharing of usage data after install	171
Use the TSM web interface	171
Use the TSM CLI	172
Basic Product Data	172
Disabling sharing of Basic Product Data on individual computers	173
Disabling the sharing of Basic Product Data at the enterprise level	173
Add an Administrator Account	174
Prerequisites	174
Use web UI	175
Use tabcmd CLI	175
Next steps	176
Initial Node Installation Defaults	176
Jump-start Installation	177
Before you begin	178
Step 1: Install Tableau Server and start Tableau Services Manager	178
Step 2: Activate and register Tableau Server	181

Step 3: Configure local identity store	185
Step 4: Add administrator account	187
Step 5: Validate your installation	188
Install Switches and Properties for Tableau Server	188
Automated Installation of Tableau Server	195
Benefits of using the automated installer	195
When not to use the automated installer	195
Before you begin	196
How to use the SilentInstaller.py script	197
Step 1: Install the automated installer	197
Step 2: Create files to provide additional configuration information required to run the automated install	198
Step 3: Run the automated install	199
Install the initial node	199
Install additional nodes	201
Update cluster topology	203
Configuration, registration, and secrets file templates	204
Secrets file template example	205
Server Configuration file template example	205
Server registration file template example	211
Install Tableau Server in a Disconnected (Air-Gapped) Environment	212
Prerequisites	212
Installing Tableau Server on an Air-Gapped Computer Running Windows	213

Activating Tableau Server in an Air-Gapped Environment	214
Offline activation overview	214
Offline activation file name changes	214
Step 1. Log in to Tableau Services Manager	215
Step 2. Determine your Tableau Server licensing type	215
Step 3 (Server ATR licensing type) Generate and copy json content to Activation page.	216
Step 3 (Legacy licensing type) Transcribe data from your air-gapped system into an activation request template.	217
Step 4. Initialize or activate your license	218
Displaying Maps in an Air-Gapped Environment	219
Configuring Tableau Server to use offline maps:	219
Clone Tableau Server	219
Security considerations	219
Limitations of the clone payload	220
Using the clone command to create a copy of Tableau Server	220
Creating the clone payload	220
Using the clone payload to create a copy of Tableau Server	221
Post Installation Tasks	221
Security Hardening Checklist	222
Installing security updates	222
1. Update to the current version	222
2. Configure SSL/TLS with a valid, trusted certificate	223

3. Disable older versions of TLS	223
4. Configure SSL encryption for internal traffic	224
5. Enable firewall protection	224
6. Restrict access to the server computer and to important directories	225
7. Update the Tableau Server Run As User account	225
8. Generate fresh secrets and tokens	225
9. Disable services that you're not using	226
JMX Service	226
10. Verify session lifetime configuration	226
11. Configure a server allowlist for file-based data sources	227
12. Enable HTTP Strict Transport Security for web browser clients	228
13. Disable Guest access	228
14. Set referrer-policy HTTP header to 'same-origin'	229
15. Configure TLS for SMTP connection	230
16. Configure SSL for LDAP	231
17. Scope permissions for non-default installation locations	231
Change List	232
Configure SMTP Setup	233
Secure SMTP	234
Use the TSM web interface	234
Use the TSM CLI	235
SMTP CLI configuration reference	237

TLS ciphers	240
Configure Server Event Notification	243
Use the TSM web interface	243
Use the TSM CLI	246
Set notification values individually	246
Set all notification values with a single json file	248
Configure Data Cache	249
Database Drivers	250
Install drivers in a cluster	250
Tableau Server Pre-Flight Check	251
tsm pre-flight check commands	251
Server Crash Reporter	252
Configure Server Crash Reporter	253
Use the TSM web interface	253
Use the TSM CLI	254
Crash reporter settings	255
Configuration template	255
Configuration file reference	255
Navigate the Admin Areas of the Tableau Web Environment	257
Access based on site role and number of sites	257
Server administrator	258
Site administrator	260

Server administrator tasks	260
Site administrator tasks	261
Move Tableau Server to Another Drive	262
Before you start	262
Tableau Server product key activation	264
Distributed and High Availability Tableau Server Installations	265
Validating your server deployment plan	265
Installation types	265
External repository	267
Prerequisite	267
Licensing	268
Creating a distributed Tableau Server installation	268
Creating a highly available (HA) Tableau Server installation	268
If an initial node fails	270
Recover from an initial node failure	270
Configure Coordination Service ensemble on additional nodes	271
Add Client File Service (CFS) to additional nodes	271
Tableau Server service license check	271
Distributed Requirements	272
Hardware	272
Hardware Guidelines for High Availability	272
Software	273

Installation location	273
Networking and Ports	273
Best Practices	274
SSL	275
Distributed Installation Recommendations	276
Recommendations for all installations	276
Install and Configure Additional Nodes	278
Installation location	278
Use the TSM web interface	278
Generate the node bootstrap file	278
Install and initialize an additional node	280
Configure the additional node with Cluster Controller	285
Use the TSM CLI	287
Generate the node bootstrap file	288
Install and initialize an additional node	289
Configure the additional node	289
Install drivers	291
Drivers and administrative views	291
Install Tableau Resource Monitoring Tool Agent	291
Database Drivers	291
Install drivers in a cluster	292
Example: Install and Configure a Three-Node HA Cluster	292

A Single Server System	293
A Three-Node System	295
Configuration steps	295
Before you begin	296
Use the TSM web interface	296
Step 1: Install the initial node	296
Step 2: Generate a bootstrap file for the additional nodes	296
Step 3: Install and initialize node 2	298
Step 4: Install and initialize node 3	303
Step 5: Configure the new node with a minimum topology	303
Step 6: Deploy a Coordination Service ensemble	305
Step 7: Configure Client File Services (CFS) on additional nodes	307
Step 8: Configure processes for node 2	308
Step 9: Configure processes for node 3	309
Use the TSM CLI	311
Step 1: Install the initial node	311
Step 2: Generate a bootstrap file for the additional nodes	311
Step 3: Install and initialize node 2	312
Step 4: Install and initialize node 3	312
Step 5: Add a process to the additional nodes	313
Step 6: Deploy a Coordination Service ensemble	313
Step 7: Configure Client File Services (CFS) on additional nodes	316

Step 8: Configure processes for node 2	317
Step 9: Configure processes for node 3	318
Step 10: Configure firewall rules (optional)	319
Add a Load Balancer	319
Add a Load Balancer	320
Configure Tableau Server to work with a load balancer	321
Deploy a Coordination Service Ensemble	321
Hardware requirements	322
The Coordination Service Quorum	322
Number of Coordination Service instances to use	322
Deploy a new Coordination Service ensemble	324
Configure Client File Service	326
Configure CFS on additional nodes	327
Repository Failover	328
Automatic repository failover	328
Manual repository failover	329
Preferred active repository	329
Recover from an Initial Node Failure	330
If an initial node fails	330
General requirements	331
Move the TSM Controller, License Service, and Activation Service to another node	332
Recover from a Node Failure	337

General requirements	338
Removing a Failed Node	338
Configure Nodes	341
Use the TSM web interface	342
Use the TSM CLI	344
Adding processes to a node	345
Changing the number of processes on a node	346
Removing all instances of a process from a node	346
Moving all instances of a process from one node to another node	347
Workload Management through Node Roles	347
Backgrounder node roles	348
Using Backgrounder node roles	348
Configuration options	349
License requirements	350
Considerations	351
File Store node roles	352
Guidelines to optimize for extract refresh and backup or restore workloads.	353
Fine tune extract query workload management	354
Configuration options	355
License requirements	356
How to see node roles	356
Who can do this	356

Install Tableau Server on a Two-Node Cluster	356
Restart Multi-Node Tableau Server Computers	357
Maintain a Distributed Environment	358
Move the Repository Process	358
Use the TSM web interface	359
Add a new instance of the repository.	359
Remove an instance of the repository.	360
Use the TSM CLI	361
Add a new instance of the repository.	361
Remove an instance of the repository.	361
Move the File Store Process	362
Use the TSM web interface	362
Adding a second instance of File Store	362
Decommissioning and removing an instance of file store	363
Use the TSM CLI	364
Adding a second instance of file store	364
Decommissioning and removing an instance of File Store	365
Move the Messaging Service Process	366
Use the TSM web interface	366
Moving the Messaging Service	366
Use the TSM CLI	367
Moving the Messaging Service	367

Remove a Node	368
Prerequisites for removing a node	368
Use the TSM web interface	369
Use the TSM CLI	370
Configure Tableau Server for High Availability with Coordination Service-Only Nodes	371
Prerequisite	372
Deploy an ensemble on Coordination Service-only nodes	372
Add a Load Balancer	374
Configure Tableau Server to work with a load balancer	375
Upgrade Tableau Server Overview	376
Choose your upgrade path	376
Blue/Green upgrades	376
Upgrading in place	376
Upgrade Type	377
Determine your Tableau Server version	377
Determine your Tableau Server install location	377
Preparing for Upgrade	378

Run Setup	401
Multi-node Upgrade -- Run Setup on Each Node	402
Run Setup	402
Multi-node Upgrade -- Run Upgrade Script	402
Run Upgrade script	402
Verify Tableau Server Upgrade	405
Verify Tableau Service processes	405
Verify TSM global settings	406
Enable subscriptions and scheduling	406
Verify user access	406
View published workbooks	407
Verify publishing workbooks and data sources	407
Verify Tableau Prep Builder	407
Verify count of Tableau objects	407
Verify API functionality	407
REST API	407
Compatibility testing	408
Post Upgrade Cleanup	408
Uninstall previous version	408
Delete 'Tableau Server' folders from \packages directory	409
Using a Blue/Green approach for upgrading Tableau Server	409

Test the Upgrade	413
Prepare a test environment	413
Upgrade the test environment	414
Confirm that everything works as expected	415
Performance and user acceptance testing	416
Test new features	416
Communicate about the upgrade	416
Troubleshoot Tableau Server Install and Upgrade	416
General Troubleshooting Steps	416
Common Tableau Server Install Issues	417
Installation logs location	417
Install program does not prompt for location to install to	417
Install program does not restart Windows	418
TSM Install fails with "initialization failed" error	418
TSM Initialize screen does not display	418
Unable to log into TSM or Tableau Server (sign in screen redisplay after entering credentials)	419
Multiple install attempts fail	419
Obliterate script generates error: "refresh-environment-variables.cmd" is not recognized as an internal or external command	420
Install fails due to hardware requirements	420
Install or upgrade fails due to CPU requirements	420
Common Tableau Server Upgrade Issues	421

Upgrade logs location	421
Error: Failed to establish a connection with Active Directory	421
Maps do not display or display incompletely after upgrading	422
Upgrade script error: "Tableau Server Version change validation failed."	422
Upgrade multi-node, initializing additional node fails with "Enter your credentials again" error	422
Upgrade stops or fails at 12%, 78%, or 92%	423
Upgrading fails due to lack of disk space	423
Upgrade fails on RebuildSearchIndex job	424
Upgrade fails on 2022.1 and later	425
Upgrade fails on 2020.4.0 or later	425
Upgrade fails due to permission problems with the backup/restore file location	426
Common Settings Import Issues	427
Import of settings file causes "not present on any node" validation error due to missing services	427
Import of settings file causes "configuration value you specified does not match" error	428
"You cannot directly modify instances of the Coordination Service" error	429
If you see this error after importing a settings file:	430
If you see the error when setting the process count for Coordination Service manually:	431
Troubleshooting connections to TSM	431
Unable to connect to TSM	431
Starting Tableau Server	432

Tableau Server cannot determine if it fully started	432
Tableau Server doesn't start	432
Reindexing Tableau Server Search & Browse	432
Problems that can be solved by rebuilding Search & Browse index	432
Activating Tableau Server	433
Tableau Server license activation fails	433
Confirm you can access the licensing server	433
Verify the date and time	435
Verify FlexNet Licensing Service has started	435
Force the product key to be read again	435
Send the contents of trusted storage to Tableau Support	436
tabcmd Installation Problems	436
Installing tabcmd separately	436
Problems installing tabcmd on Linux	436
Java is not installed	437
Incorrect version of Java is installed	437
Uninstall Tableau Server	437
Uninstalling and completely removing Tableau Server	438
Uninstall a Tableau Server version	438
Remove Tableau Server from Your Computer	439
What tableau-server-obliterate does	441
Preserving Tableau Server backup and log files	441

Running the tableau-server-obliterate script	442
To completely remove Tableau Server without removing server licensing	442
To completely remove Tableau Server and licensing	443
Help Output for tableau-server-obliterate Script	444
Output	444
Migrate	446
Migrate Tableau Server to Tableau Cloud	446
Technical Considerations for Migrating from Tableau Server to Tableau Cloud	446
Summary outline	447
Security, administration, and governance	449

What to expect when enabling Catalog	708

Initial ingestion	708
Initial ingestion speed	708
Disk space to store metadata	708
Memory for non-interactive microservice containers	709
Best practices for enabling Catalog	710
Summary of steps to enable Catalog	710
Enable Catalog	711
Step 1: Determine the amount of content on Tableau Server	711
Step 2: Estimate how long initial ingestion will take	711
Step 3: Decrease the time of initial ingestion	712
Step 4: Activate the Data Management license	713
Step 5 (optional): Turn off Catalog capabilities for each site	713
Step 6: Run the tsm maintenance metadata-services command	714
Step 7: Monitor initial ingestion progress and validate its status	715
Step 8: Configure SMTP Setup	715
Step 9 (optional): Turn on Catalog capabilities for each site	715
Troubleshoot Catalog	715
Timeout limit and node limit exceeded messages	715
Missing content	716
Performance after initial ingestion	717
Out of memory errors	718
Disable Catalog	718

Turn off Catalog capabilities for each site	718
Stop indexing metadata on Tableau Server	718
Get Initial Ingestion Status	718
Step 1: Authenticate using the REST API	719
Step 2: Make a GET request	719
Status values from the response	719
Example response	720
Get Eventing Status	724
Step 1: Authenticate using the REST API	724
Step 2: Make a GET request	724

Step 1: Set default directives	1481

Step 2: Add additional directives (optional)	1483
Step 3: Specify report-only directives (optional)	1484
Step 4: Enable CSP on Tableau Server	1484
Step 5: Run tsm pending-changes apply	1485
View CSP report	1485
SSL	1486
Configure SSL for External HTTP Traffic to and from Tableau Server	1486
SSL certificate requirements	1487
Configuring SSL for a Cluster	1488
SSL with multiple gateways	1489
Additional configuration information for Tableau Server cluster environments	1489
Prepare the environment	1490
Configure SSL on Tableau Server	1490
Use the TSM web interface	1490
Use the TSM CLI	1491
Port redirection and logging	1492
Change or update SSL certificate	1492
Example: SSL Certificate - Generate a Key and CSR	1493
Steps to generate a key and CSR	1494
Configure a certificate for multiple domain names	1494
Set the OpenSSL configuration environment variable (optional)	1494
Generate a key	1495

Create a certificate signing request to send to a certificate authority	1495
Send the CSR to a certificate authority to obtain an SSL certificate	1496
Use the key and certificate to configure Tableau Server	1497
For SAN certificates: modify the OpenSSL configuration file	1497
Additional information	1499
Configure SSL for Internal Postgres Communication	1499
Use the TSM web interface	1499
Use the TSM CLI	1501
What the command does	1501
Option for repository-ssl enable	1502
Cluster environments	1502
Configure Custom SSL Certificate for TSM Controller	1502
Default TSM SSL functionality	1503
Tableau Server v2023.1 SSL custom certificate	1503
Configuration	1504
Configure Postgres SSL to Allow Direct Connections from Clients	1504
Configure Mutual SSL Authentication	1505
User authentication session time limits	1506
Certificate usage	1506
Client certificate requirements	1507
Use the TSM web interface	1508
Use the TSM CLI	1510

Step 1: Require SSL for external server communication	1510
Step 2: Configure and enable mutual SSL	1510
Additional options for mutual SSL	1511
Fallback authentication	1511
User name mapping	1512
Certificate Revocation List (CRL)	1512
Mapping a Client Certificate to a User During Mutual Authentication	1512
User-name mapping options	1513
Change the certificate mapping	1514
Address user-name mapping ambiguity in multi-domain organizations	1515
Configure Encrypted Channel to LDAP External Identity Store	1515
Certificate requirements	1516
Import certificate into the Tableau keystore	1517
LDAPS encryption method	1517
Configure encrypted channel for simple bind	1518
When to configure	1518
For new installations of Tableau Server	1518
Security Hardening Checklist	1518
Installing security updates	1519
1. Update to the current version	1519
2. Configure SSL/TLS with a valid, trusted certificate	1519
3. Disable older versions of TLS	1519

4. Configure SSL encryption for internal traffic	1520
5. Enable firewall protection	1521
6. Restrict access to the server computer and to important directories	1521
7. Update the Tableau Server Run As User account	1521
8. Generate fresh secrets and tokens	1522
9. Disable services that you're not using	1522
JMX Service	1522
10. Verify session lifetime configuration	1523
11. Configure a server allowlist for file-based data sources	1523
12. Enable HTTP Strict Transport Security for web browser clients	1524
13. Disable Guest access	1525
14. Set referrer-policy HTTP header to 'same-origin'	1526
15. Configure TLS for SMTP connection	1527
16. Configure SSL for LDAP	1528
17. Scope permissions for non-default installation locations	1528
Change List	1529
Manage Licenses	1530
Licensing Overview	1530
Activation	1531

Error Handling	1563
Troubleshoot Licensing	1566
Product key failure with forward proxy servers	1566
Handle an unlicensed server	1566
Unlicensed role-based server	1567
Unlicensed core-based server	1567
Unlicensed server administrator	1567
Troubleshoot role-based licensing	1568
A user or administrator is unlicensed due to license expiration	1568
Server Administrator site role is unchanged when using a Creator license	1570
Licenses are not immediately available	1570
A user with a Viewer license cannot open Tableau Server or Tableau Cloud workbooks from Tableau Desktop	1570
Migrate from Core-Based to Role-Based Licensing	1570
Prepare for migration to role-based licensing	1571
Migrate to role-based licensing	1571
Use role-based licenses on a server with core-based licensing	1572
Example of completing a migration from core-based licensing	1573
Quick Start: Use Login-based License Management with Tableau Server	1573

Step 1: Install Tableau Server	1573
Step 2: Add authorized users to Tableau Server	1574
Step 3: Activate Tableau Desktop or Tableau Prep Builder	1574
Login-based License Management	1575
How login-based license management works	1576
Login-based license management with Tableau Cloud	1577
Login-based license management with Tableau Server	1577
Use login-based license management	1578
Step 1: Install Tableau Server	1578
(Optional) Step 2: Change login-based license management settings	1579
Login-based license management settings	1583
Microsoft Windows	1586
macOS	1587
(Optional) Step 3: Change the authorization to run (ATR) duration	1587
Step 4: Activate Tableau Desktop	1589
View login-based license usage	1591
Troubleshooting	1592
Login-based license management is not enabled on Tableau Server	1592
Login-based license management is not enabled on Tableau Desktop	1593
Product key expiration date doesn't change after purchasing a year sub- scription	1593
You do not have a Creator license	1593
You have activated the maximum number of computers	1594

To shorten the ATR token duration for maximum activation	1594
To return your computer to an unlicensed state	1595
Your Tableau credentials are invalid	1596
Your computer's clock is not synchronized to the current time	1596
Unable to activate with your credentials	1596
Zero Downtime Licensing	1597
When should you restart Tableau Server?	1597
About the Identity Migration	1598
Summary of steps for existing deployments	1599
Key terms	1599
Purpose of the identity migration	1600
What happens during the identity migration	1601
Step 1: Before you begin	1602
Step 2: Start the identity migration	1603
Step 3: Complete the identity migration	1603
Step 4: Configure Tableau Server to use the Identity Service	1605
Manage the Identity Migration	1605
Manage identity migration jobs	1607
Change identity migration settings	1609
Migration settings	1610
Disable identity migration	1612
Complete the identity migration and configure the Identity Service	1612

Step 1: Validate and complete the identity migration	1612
Step 2: Configure Tableau Server to use the Identity Service	1613
Resolve Identity Migration Conflicts	1614
Step 1: Resolve identity conflicts	1614
Quick reference: Identity conflicts	1615
Step 2: Complete the identity migration	1617
Step 3: Configure Tableau Server to use the Identity Service	1618
Troubleshoot Issues with the Identity Migration	1619
Unable to restore backup	1619
Step 1: Enable legacy-identity-mode and restore the backup	1619
Step 2: Validate and complete the identity migration	1620
Step 3: Configure Tableau Server to use the Identity Service	1621
"Unexpected error" on Identity Migration page	1621
Migration progress appears unresponsive or stuck	1622
"Identity migration is in progress" pop-up persists	1623
Identity Migration page disappears	1623
Users can't sign in	1623
Revert identity migration	1624
Provision and Authenticate Users Using Identity Pools	1624
What are identity pools?	1625
When to use identity pools	1626
More about identity pools	1626

Initial pool (TSM configured) versus identity pools	1626
Identity pools impact on users' sign-in experience	1627
Username and identifiers in Tableau	1627
Set Up and Manage Identity Pools	1628
Prerequisites	1629
Get started	1629
Step 1: Configure Tableau Server and establish a session	1629
Step 2: Set up an identity store	1631
Example	1631
URI	1631
Example	1632
URI	1632
Request body (JSON)	1632
Response body	1632
Step 3: Set up authentication	1632
Example	1634
URI	1634
Request body (JSON)	1634
Response body	1634
Step 4: Create an identity pool	1634
Example	1635
URI	1635

Request body (JSON)	1636
Example response body	1636
Step 5: Add users to identity pool	1636
Test identity pools	1639
Manage identity pools	1639
Troubleshoot identity pools	1639
Limitations of identity pools	1639
Tableau Server landing page shows IdP errors	1640
Add Users to Tableau Server	1640
Before you begin	1640
When adding users at the server level versus the site level	1641
Add a user to the server	1642
No identity pools configured	1642
One or more identity pools configured	1645
Sign in to the Tableau Server Admin Area	1650
Reset the server administrator account and password	1652
Navigate the Admin Areas of the Tableau Web Environment	1652

Troubleshoot Tableau Server Install and Upgrade	2399
General Troubleshooting Steps	2399
Common Tableau Server Install Issues	2400
Installation logs location	2400

Install program does not prompt for location to install to	2400
Install program does not restart Windows	2401
TSM Install fails with "initialization failed" error	2401
TSM Initialize screen does not display	2401
Unable to log into TSM or Tableau Server (sign in screen redisplay after entering credentials)	2402
Multiple install attempts fail	2402
Obliterate script generates error: "refresh-environment-variables.cmd" is not recognized as an internal or external command	2403
Install fails due to hardware requirements	2403
Install or upgrade fails due to CPU requirements	2403
Common Tableau Server Upgrade Issues	2404
Upgrade logs location	2404
Error: Failed to establish a connection with Active Directory	2404
Maps do not display or display incompletely after upgrading	2405
Upgrade script error: "Tableau Server Version change validation failed."	2405
Upgrade multi-node, initializing additional node fails with "Enter your cre- dentials again" error	2405
Upgrade stops or fails at 12%, 78%, or 92%	2406
Upgrading fails due to lack of disk space	2406
Upgrade fails on RebuildSearchIndex job	2407
Upgrade fails on 2022.1 and later	2408
Upgrade fails on 2020.4.0 or later	2408

Upgrade fails due to permission problems with the backup/restore file location	2409
Common Settings Import Issues	2410
Import of settings file causes "not present on any node" validation error due to missing services	2410
Import of settings file causes "configuration value you specified does not match" error	2411
"You cannot directly modify instances of the Coordination Service" error	2412
If you see this error after importing a settings file:	2413
If you see the error when setting the process count for Coordination Service manually:	2414
Troubleshooting connections to TSM	2414
Unable to connect to TSM	2414
Starting Tableau Server	2415
Tableau Server cannot determine if it fully started	2415
Tableau Server doesn't start	2415
Reindexing Tableau Server Search & Browse	2415
Problems that can be solved by rebuilding Search & Browse index	2415
Activating Tableau Server	2416
Tableau Server license activation fails	2416
Confirm you can access the licensing server	2416
Verify the date and time	2418
Verify FlexNet Licensing Service has started	2418
Force the product key to be read again	2418

Send the contents of trusted storage to Tableau Support	2419

RMT Agent initialization options	2700
External Repository for Tableau Resource Monitoring Tool	2703
New installation of Resource Monitoring Tool	2704
Existing Resource Monitoring Tool installation	2707
Manually migrating local Resource Monitoring Tool repository to an external AWS PostgreSQL DB instance	2708
Step 1: Create an RDS instance to host the external repository	2708
Step 2: Test to make sure you are able to connect to the new database	2709
Step 3: Obtain the admin password for the local PostgreSQL database cur- rently used by RMT	2709
Step 4: Take a backup of the existing PostgreSQL database	2710
Step 5: Configure RMT Server to point to the external repository	2710
Step 6: Restore the back up to the external repository	2711
Step 7: Start the RMT Server	2711
Step 8: Re-register Agents	2711
Step 9: Verify that RMT Server is running and you are seeing the historical data	2712
Upgrade best practices	2712
Upgrading when the new version of RMT requires a major version PostgreSQL upgrade	2713
Recovering from a failed upgrade	2714
RMT and PostgreSQL version compatibility	2714
Who can do this	2714

External Message Queue Service (RabbitMQ) for Tableau Resource Monitoring Tool	2715
New installation of Resource Monitoring Tool	2715
Existing installations of Tableau Resource Monitoring Tool	2717
Migrating to external AWS AMQ	2718
Step1: Create Amazon AMQ for Rabbit MQ to host the external message queue service with the following recommendations.	2718
Step 2: Test the connection from RMT Server	2718
Step 4: Verify the queue.	2719
Step 5 : Configure RMT Server to use the new Amazon MQ service	2719
Step 6: Start the RMT Server	2719
Step 7: Re-register Agents	2720
Step 8: Verify that RMT Server is running	2720

About Tableau Help

Addressing implicit bias in technical language

In an effort to align with one of our core company values, equality, we have changed terminology to be more inclusive where possible. Because changing terms in certain places can cause a breaking change, we maintain existing terminology in the following places:

- Tableau APIs: methods, parameters, and variables
- Tableau CLIs: commands and options
- Tableau Resource Monitoring Tool installers, installation directories, and terms in configuration files
- Third-party systems documentation

For more information about our ongoing effort to address implicit bias, see [Salesforce Updates Technical Language in Ongoing Effort to Address Implicit Bias](#) on the Salesforce website.

Deprecated and retired features

Beginning in October, 2023, we are making the following adjustments to our use of terms in the Tableau Help:

- **Deprecated:** A deprecated feature is one that is scheduled to be retired from Tableau in a future release.
- **Retired:** A retired feature is one that no longer is available in the latest version of Tableau. It has been removed from the software.

Features that have been deprecated or retired may still be documented for customers who are running older, still supported versions of Tableau.

Tableau Server Release Notes

This topic describes what's new in the latest release. Use the viz below to explore new features in Tableau Server. Click on a feature to bring up the tooltip with a link to detailed documentation for that feature. Explore the filters to refine your search. Download the data to create a customized list.

- Use the Search by **Feature** dashboard to see a list of new features for a product or version, or explore when a feature was released. The dashboard currently defaults to Server for the latest version of Server.
- Use the **Upgrade Server** dashboard to see a list of features specific to your upgrade. The upgrade view includes filters that allow you to filter for new or changed features. Features that are listed under the **changed** status are typically features that can impact upgrade. The list features categorized as changed might be useful to prepare and test your upgrades.

Plan Your Deployment

The articles in this section provide information on planning a Tableau Server deployment.

In addition to consulting the articles in this section, we recommend that you review [Tableau Blueprint](#) as a first step in your planning workflow. Tableau Blueprint is a step-by-step guide to becoming a data-driven organization.

Validating your server deployment plan

Before you commit to installing a new Tableau Server deployment in your organization, be sure to carefully evaluate your options. For most organizations, Tableau Cloud will provide a more reliable, performant, and cost-effective analytics solution when compared to self-hosting Tableau Server. For information about the viability of Tableau Cloud for your organization, review this blog post, [Should I move my analytics to the cloud?](#)

Already running Tableau Server and want to migrate to Tableau Cloud? See [Tableau Cloud Manual Migration Guide](#).

If you have determined that you must self-host Tableau Server, we recommend following the prescribed Tableau deployment in the [Enterprise Deployment Guide](#) (EDG). The EDG presents a fully-tested and supported, performant, scalable, secure reference architecture based on a tiered data network. Moving forward, we are committed to investing in the EDG reference architecture to ease feature rollouts and improve upgrade scenarios.

Server Administrator Overview

Tableau Server on Windows integrates with a number of components in your IT infrastructure to provide a unique self-service data analytics culture for your users. It's important that you, as a server administrator, understand how Tableau Server fits into your IT infrastructure.

The topics in this section provide information on planning, deploying, tuning, and managing Tableau Server.

If you are deploying Tableau Server as part of a broader effort to transform your organization into a data-driven culture, see [Tableau Blueprint](#). Tableau Blueprint is a step-by-step guide to becoming a data-driven organization, whether your organization is new to modern, self-service analytics or you've already deployed and need to broaden, deepen, and scale the use of data.

This topic provides a brief overview of how to think about Tableau Server and how it interacts with your existing IT infrastructure.

Looking for Tableau Server on Linux? See [Server Administrator Overview](#).

Validating your server deployment plan

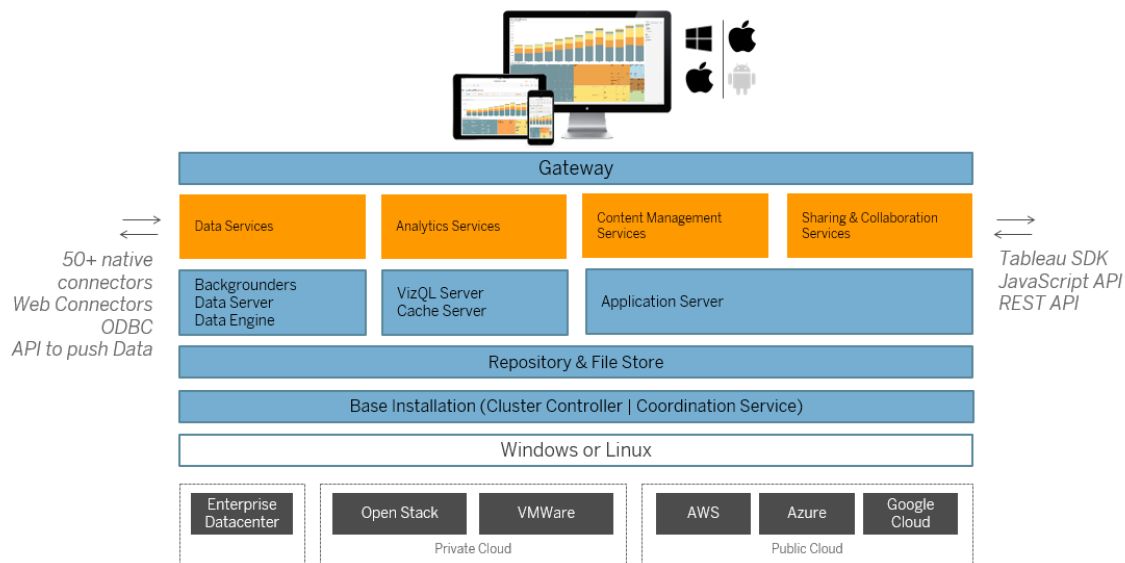

Before you commit to installing a new Tableau Server deployment in your organization, be sure to carefully evaluate your options. For most organizations, Tableau Cloud will provide a more reliable, performant, and cost-effective analytics solution when compared to self-hosting Tableau Server. For information about the viability of Tableau Cloud for your organization, review this blog post, [Should I move my analytics to the cloud?](#)

Already running Tableau Server and want to migrate to Tableau Cloud? See [Tableau Cloud Manual Migration Guide](#).

If you have determined that you must self-host Tableau Server, we recommend following the prescribed Tableau deployment in the [Enterprise Deployment Guide](#) (EDG). The EDG presents a fully-tested and supported, performant, scalable, secure reference architecture based on a tiered data network. Moving forward, we are committed to investing in the EDG reference architecture to ease feature rollouts and improve upgrade scenarios.

Architectural overview

Tableau Server is a collection of processes that work together to provide a full self-service analytic platform for your users. The following diagram shows a high-level architectural view of Tableau Server.

Multiple server processes (shown in blue above) work together to provide services at various tiers. The Gateway process is the component that redirects traffic from all Tableau clients to the available server nodes in a cluster.

Data Services is a logical grouping of services that provide data freshness, shared meta data management, governed data sources, and in-memory data. The underlying processes that power Data Services are the Backgrounder, Data Server and Data Engine processes.

Analytics Services, composed of the VizQL and Cache Server processes, provide user-facing visualization and analytics services and caching services.

Sharing and Collaboration, and Content Management Service are powered by the Application Server process. Core Tableau Server functionality such as user login, content management (projects, sites, permissioning, etc.) and administration activities are provided by the Application Server process.

All of the above services use and rely on the Repository process, which contains structured relational data like metadata, permissions, workbooks, data extracts, user info, and other data. The File Store process enables data extract file redundancy across the cluster and ensures extracts are locally available on all cluster nodes. Under heavier loads, extract files are available locally across the cluster for faster processing and rendering.

Tableau's architecture is flexible, allowing you to run the platform just about anywhere. You can install Tableau Server on-premises, in your private cloud or data center, on Amazon EC2, on Google Cloud Platform, or on MS Azure. Tableau analytics platform can also run atop virtualization platforms. We recommend you follow the best practices for each virtualization platform to ensure the best performance from Tableau Server.

Tableau and your data

When you install Tableau Server into your organization, it becomes a core component of the analytics pipeline to the data your users need. It's important to understand how Tableau Server interacts with your business data. Specifically, Tableau Server can store extracts of data in your organization. It can also connect to live data sources. How you choose to provide the data to your Tableau users is informed by a number of variables: data source type, user scenario, performance and access requirements, and infrastructure conditions.

Tableau Server has not been architected as a data warehouse server where static, native data files are housed. In fact, using Tableau Server as a traditional data warehouse is a poor use of your investment. Rather, when it comes to data storage, we recommend hosting optimized data extracts on Tableau Server. While a data extract is often a subset of a larger data source in your organization, you can also create extracts for data sources that are overtaxed during work hours by [scheduling the extract refresh](#) for off-hours.

Extracts are also useful for modeling data or to enable highly-performant visualization authoring. For example, to improve visualization authoring and interaction performance you may optimize extracts by filtering the source data to the essential fields for a given department or project. Extracts can be resource intensive. If your organization plans to make heavy use of extracts, review the topic, [Optimize for Extracts](#).

Tableau Server also provides direct, authorized access to live data sources, allowing users to build and run complex filtered queries against a variety of connected data sources. For this scenario, Tableau requires highly performant network access to the data sources in your organization and to those in the cloud. Tableau Server and the target data sources also need to be properly sized to handle the processing load required by high-volume, complex data operations. You can optimize performance for live data connections with caching configurations and specifying initial SQL commands.

User access

Tableau Server is also a web-based collaboration platform, where users connect to share, view, and interact with data visualizations and data sources from a variety of devices. This means that Tableau Server must be accessible to Tableau users within your local protected network. You can also extend access to data visualizations to desktop, mobile, and authenticated web users outside your organization.

Tableau Server integrates with the following user **authentication** solutions: Active Directory, SAML, OpenId, and Kerberos.

Where should I install Tableau Server in my network?

Because of the highly-sensitive nature of most data that organizations manage with Tableau Server, and because Tableau Server requires access to internal data stores, Tableau Server must be run inside a protected network. Authenticated access from the internet is configured to connect to Tableau Server through a **reverse proxy** or a VPN solution.

Some organizations embed Tableau views in public webpages, or, for internal users, on generic web servers on the internal network.

Tableau Server can be configured to support such scenarios with either authenticated or anonymous access. For authorized access, where users can only view underlying data to which they have permission, you can configure trusted tickets with a generic web server. In this scenario, Tableau Server authorizes access to the underlying data in an embedded view. This scheme enables you to host interactive data visualizations on a web server in a DMZ or outside the protected network.

Anonymous access to embedded Tableau views requires that you enable **"guest user"** for Tableau Server. Guest user also requires that you license Tableau Server according to the number of cores you are running, rather than a named-user (interactor) model.

Sizing and scalability

Depending on the size and data usage in your organization, you can scale Tableau Server up or out. As you scale your server, you can also selectively allocate resources to meet your data needs and user needs.

When you scale up Tableau Server, you add hardware resources to a single server. For example, you might increase the memory and processing power of the computer running Tableau Server.

When you scale out Tableau Server, you add computers (or nodes). To create a highly available deployment with failover, you need at least three nodes. For example, you might run most CPU-intensive server processes on two nodes and use the third node for the gateway and coordination controller services.

Whether you scale up or scale out, you can selectively allocate resources by configuring the number and type of server processes that run. If your organization has a lot of data and creates a lot of data extracts, you can increase the number of processes that are dedicated to refreshing and storing extracts. Alternatively, if your organization wants to optimize for heavy user loads, you can increase the number of processes dedicated to responding to user requests. Additionally, you can integrate Tableau Server into industry-standard network load balancers to further optimize your server for user requests.

Tableau Server management model

Tableau Server has been designed to support a management scheme with two high-level administrators: server administrator and site administrator. In small organizations, these roles may be assumed by the same person or team, but in larger organizations, the roles often diverge.

In this model, server administrators are IT professionals who maintain and deploy heterogeneous server solutions. Essential areas for server administrators may include networking, hardware tuning and maintenance, security and access, and managing users and directory services. The tools and documentation that we deliver with Tableau Server for the server administrator support these core server IT areas.

Site administrator, on the other hand, is an administrative role specific to Tableau Server or Tableau Cloud deployments. The Tableau site administrator is fundamentally concerned with data content. The site administrator manages users and their access to projects, workbooks, and data sources. To learn about sites and how to plan your deployment for them, see [What is a site](#)

Administrative roles

In some small organizations a single administrator may manage the entirety of Tableau Server. But for bigger enterprise organizations, Tableau Server usually requires at least three administrative roles for management at scale.

Tableau Server administrator

The Tableau Server administrator has access to administrative pages for creating and editing sites, adding users and setting roles, and many content-related tasks after the Tableau Server installation is complete. The Tableau Server administrator also creates and manages other server and site administrators, who in turn may manage sites, user groups, and projects.

For information about signing into Tableau Server as a Tableau Server administrator, see [Sign in to the Tableau Server Admin Area](#).

TSM administrator

Tableau Services Manager (TSM) is a tool that gives server administrators command-line and web-based options for installing, upgrading, configuring, and maintaining Tableau Server. The TSM administrator installs the server and performs server-related administrative task like backing up server data, restoring backups, creating log archives, and managing multi-node clusters.

The TSM administrator must be an administrator on the local computer. See [Sign in to Tableau Services Manager Web UI](#).

Common tasks performed by the TSM administrator include:

- Initial configuration of Tableau Server after installation
- Ongoing configuration management, including editing settings and changing the server topology
- Running administrative tasks such as backup, restore, and ziplogs

To learn more about TSM, see [Tableau Services Manager Overview](#).

Tableau portal administrator

An important administrative role in a Tableau Server deployment is the Tableau customer portal administrator. The portal administrator manages licensing and the associated keys for the Tableau deployment. As the portal administrator, your first step is to purchase licenses on the [Tableau Customer Portal](#). When you purchase licenses, the portal will return corresponding product keys. To renew your license, visit the [Tableau renewal](#) web page.

Tableau has a number of products (Desktop, Server, Prep Builder, and more). Each of the Tableau products require that you activate licenses by updating the Tableau software with the product keys that are purchased and stored on the Tableau Customer Portal. As the administrator who is tasked with activating Tableau licenses, it is important that you understand the relationship between licenses and keys. See [Understanding License Models and Product Keys](#).

Management tools

Tableau Server includes a number of toolsets for managing the system:

- **Tableau Server administrator page:** This is the web-based administrative site that is installed on each Tableau Server instance. Tasks performed on the administrator page are day-to-day tasks for both server and site administrators. Server-related tasks include creating sites and site administrator accounts, optionally importing users, setting up synchronization with directory services, setting up extract refresh schedules, monitoring server performance and usage, and other global settings.

Site-related tasks include managing content and assign permissions, running extract refreshes, create groups and projects, monitoring site activity, optionally adding users, and other content-related tasks.

See [Navigate the Admin Areas of the Tableau Web Environment](#).

Permissions required for the Tableau Server administrator page are based on site roles. The site roles are generated and managed by Tableau Server.

- **tsm Command Line Reference** - This is the primary interface for server-wide configurations. Many configurations made with TSM CLI are rarely revisited after initial configuration. For example: SSL, subscriptions, data caching, service account, SMTP alerting, user authentication, and single-sign on configuration are all performed with TSM CLI.
- You can also Sign in to Tableau Services Manager Web UI.
- **tabcmd**: You can use the tabcmd command-line utility on a Windows or Linux computer to create scripts to automate administrative tasks on your Tableau Server sites. For example, use tabcmd for creating or deleting users, projects, and groups.
- **REST API**: With the Tableau Server REST API you can manage and change Tableau Server resources programmatically, via HTTP. The API gives you simple access to the functionality behind the data sources, projects, workbooks, site users, and sites on a Tableau server. You can use this access to create your own custom applications or to script interactions with Tableau Server resources.

Security

As an application server connecting to data that may be highly-sensitive, Tableau Server supports and implements a number of industry security standards. Our server admin documentation includes best practices and implementation for user authentication, authorization, data security, and network security. While our default installation is secure by design, we also recommend following the [security hardening checklist](#) to further lock down your deployment.

For more information about security audit compliance, vulnerability reporting, and other security resources, visit <http://www.tableau.com/security>.

Tableau Services Manager Overview

This article provides an overview of Tableau Services Manager (TSM), which you can use to configure and administer Tableau Server. Beginning with version 2018.2, TSM is available for Tableau Server on Windows, both as a CLI and as a Web UI.

- [Functionality](#)
- [Components](#)

- [Authentication](#)
- [Connecting](#)

Functionality

TSM gives server administrators command-line and web-based options for configuring and maintaining Tableau Server, including performing administrative task like backing up server data, restoring backups, creating log archives, and managing multi-node clusters. For example, you use TSM to perform the following tasks:

- Initial configuration of Tableau Server after installation
- Ongoing configuration management, including editing settings and changing the server topology
- Running administrative tasks such as backup, restore, and ziplogs

For administrators familiar with earlier versions of Tableau Server, TSM replaces the following tools from previous versions of Tableau Server:

- Tableau Server Configuration utility
- tabadmin command line utility
- Tableau Server Monitor

Components

TSM consists of *services* (called *processes* in this documentation) and *clients*. TSM processes are administrative services which manage Tableau Server processes. TSM processes run continuously after TSM is initialized, even when the rest of Tableau Server is offline.

TSM processes that run, even when Tableau Server is stopped include:

- Administration Agent
- Administration Controller
- Client File Service
- Coordination Service (based on Apache Zookeeper™)
- Service Manager
- Licensing Service

For more information about TSM processes and Tableau Server processes, see [Tableau Server Processes](#).

TSM Authentication

Whether you use the TSM Web UI, the command line interface, or the TSM API, you need to authenticate to Tableau Server before you can perform administrative tasks. This user account is distinct from Tableau Server user accounts, including Tableau Server administrators and site administrators.

You authenticate to TSM with a user that exists on the Tableau Server computer. The TSM user account must use password-based authentication. By default, the TSM user account must be a member of the Administrators group on the computer where Tableau Server is running. Alternatively, you can specify a Windows group for TSM administration after you have installed Tableau Server. See [Configure a Custom TSM Administration Group](#).

Connecting TSM clients

As a security measure, you can only connect to TSM with clients (CLI, Web UI, Rest API) over HTTPS. This is because TSM allows you to perform administrative tasks and to connect to TSM from other computers.

When you are connecting with a TSM client, you must connect to the Tableau Server instance running the TSM Administration Controller service.

Note: The TSM CLI tool does not require admin credentials in some scenarios. Specifically, if the account you are logged in as is a member of the TSM-authorized group, you do not need to provide credentials to run commands when running tsm CLI locally. For more information, see [Authenticating with tsm CLI](#).

TSM HTTPS connections rely on a self-signed certificate generated by the Tableau Server installer. This certificate is the Tableau installation CA certificate that signs the

SSL certificates Tableau creates for encrypting traffic over HTTP. The Tableau installation CA certificate must be trusted by the systems connecting to TSM Administration Controller.

The TSM CLI client validates certificate trust from a different store than the TSM Web UI uses. The TSM CLI client refers to the trusted store in the local Java keystore to validate trust for CA certificates. Since the TSM Web UI must establish connection with a web browser, trust is validated with the operating system's trusted keystore. The difference in how CA certificates are stored determines different trust configuration scenarios as outlined here:

- For TSM Web UI and CLI communications on Tableau Server, the certificate trust is configured by default as part of the installation, node bootstrap, and upgrade processes. The Tableau installation CA certificate is added to the trusted store in both the Java keystore and in the Windows trusted root keystore. This allows you to access TSM from any computer in the cluster without additional configuration.
- For TSM CLI connections from remote computers, you will be prompted to trust the Tableau installation CA certificate the first time you connect to the Tableau Server running TSM Administration Controller. You can choose to trust the CA certificate, in which case you will not be prompted again on that computer until the certificate expires (default is 3 years). Or you can connect with a one-time trust by running your TSM command with the `--trust-admin-controller-cert` flag.
- For TSM Web UI connections from remote computers, the browser will prompt you to trust the host running TSM Administration Controller service.

Infrastructure Planning

Before you install Tableau Server, you should review the disk requirements, recommended configurations, user accounts, security, and networking requirements.

Validating your server deployment plan

Before you commit to installing a new Tableau Server deployment in your organization, be sure to carefully evaluate your options. For most organizations, Tableau Cloud will provide a more reliable, performant, and cost-effective analytics solution when compared to self-hosting Tableau Server. For information about the viability of Tableau Cloud for your organization, review this blog post, [Should I move my analytics to the cloud?](#)

Already running Tableau Server and want to migrate to Tableau Cloud? See [Tableau Cloud Manual Migration Guide](#).

If you have determined that you must self-host Tableau Server, we recommend following the prescribed Tableau deployment in the [Enterprise Deployment Guide](#) (EDG). The EDG presents a fully-tested and supported, performant, scalable, secure reference architecture based on a tiered data network. Moving forward, we are committed to investing in the EDG reference architecture to ease feature rollouts and improve upgrade scenarios.

Before you install...

Note: You can find additional information about technical specifications for Tableau Server on the Tableau web site, [here](#).

This topic includes requirements and recommendations that you must consider before you install Tableau Server into a production environment.

- If you are new to Tableau Server, and you want to deploy it in your organization, we encourage you to deploy Tableau Server as a single server in a test environment first. The easiest way to do a single-server installation is to follow the steps in Jump-start Installation.
- If you are deploying Tableau Server in a distributed cluster, review Distributed Requirements in addition to the requirements and recommendations described in this topic.

Validating your server deployment plan

Before you commit to installing a new Tableau Server deployment in your organization, be sure to carefully evaluate your options. For most organizations, Tableau Cloud will provide a more reliable, performant, and cost-effective analytics solution when compared to self-hosting Tableau Server. For information about the viability of Tableau Cloud for your organization, review this blog post, [Should I move my analytics to the cloud?](#)

Already running Tableau Server and want to migrate to Tableau Cloud? See [Tableau Cloud Manual Migration Guide](#).

If you have determined that you must self-host Tableau Server, we recommend following the prescribed Tableau deployment in the [Enterprise Deployment Guide](#) (EDG). The EDG presents a fully-tested and supported, performant, scalable, secure reference architecture based on a tiered data network. Moving forward, we are committed to investing in the EDG reference architecture to ease feature rollouts and improve upgrade scenarios.

Hardware recommendations for production installations

The following list describes the minimum hardware recommendations for a production use, single- node installation of Tableau Server:

Important: These recommendations are minimums and may not reflect the requirements for your installation and organization. For example, there are a number of factors that can impact disk space requirements, including whether or not you will be publishing extracts, flows, and the number of workbooks to Tableau Server. For more information on what might impact free disk space requirements, see [Disk Space Requirements](#).

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
Single node	<ul style="list-style-type: none"> 64-bit (x64 chipsets) Must support SSE4.2 and POPCNT instruction sets ARM-based processors are not supported 	8 cores (16 vCPUs), 2.0 GHz or higher	Version 2022.3 and later: <ul style="list-style-type: none"> 128 GB Version 2021.4.0 to version 2022.1.x: <ul style="list-style-type: none"> 64 GB Version 2021.3.x and earlier:	50 GB

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
				<ul style="list-style-type: none"> • 32 GB
				<p>If you are adding Tableau Prep Conductor to your Tableau Server installation, we recommend you add a second node and dedicate this to running Tableau Server Prep Conductor. This node should have a minimum of 4 cores (8 vCPUs), and 16 GB of RAM.</p>
Multi-node and enterprise deployments	Contact Tableau for technical guidance.			<p>Nodes must meet or exceed the minimum hardware recommendations, except:</p> <ul style="list-style-type: none"> • Dedicated Backgrounder nodes running up to two instances of backgrounder, where 4 cores may be acceptable. • Dedicated node for Tableau Prep Conductor: Minimum of 4 cores (8 vCPUs), and 16 GB of RAM. • Dedicated node for Independent Gateway: Minimum of 2 cores (4 vCPUs), 8 GB of RAM, and 100 GB free disk space.

Important: The disk space requirement cannot be checked until you initialize TSM.

- Free disk space is calculated after the Tableau Server Setup program is unzipped. The Setup program uses about 1 GB of space. You may need to allocate additional disk space depending on various factors like whether you will be using extracts.
- **Network attached storage space requirements for External File Store:** If you are planning to configure [Tableau Server with External File Store](#), you will need to estimate the amount of storage space to dedicate on your network attached storage.

Estimating the storage size: You must take into account the amount of storage needed for publishing and refreshing extracts. In addition, you must also take into account the

repository backup size unless you specifically choose the option to do your repository backup separately as described in the Option 2: Back up repository separately topic.

- Extracts:
 - Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.
 - Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.
- Repository Backup:
 - To obtain an estimate of the repository data, check the size of `<data directory>/pgsql/data/base` directory.
 - To obtain the exact size of the repository data, open the backup file and use the size of the `workgroup.pg_dump` file.
- Core count is based on "physical" cores. Physical cores can represent actual server hardware or cores on a virtual machine (VM). Hyper-threading is ignored for the purposes of counting cores.
- RAM shown is the minimum recommended for a single-node installation. Your installation may function better with more RAM, depending on activity, number of users, and background jobs, for example.

To see the full list of recommendations and to see the minimum requirements, see Minimum Hardware Requirements and Recommendations for Tableau Server. For hardware specifications Tableau uses internally for testing scalability, see Hardware recommendations for production installations.

For public cloud deployments on Amazon Web Services and Google Cloud Platform, their "vCPU" is actually a CPU hyper-thread, and not a full CPU core. When sizing cloud instances,

you will need twice as many vCPU as the Tableau Server CPU core requirements given (8 vCPU required for a minimum trial installation, 16 vCPU recommended for a single-node installation).

Operating system requirements

The following 64-bit Microsoft Windows Server operating systems are supported

Note: Windows Server 2022 is *not* supported. Beginning in April 2023, installers for all versions of Tableau Server on Windows will block installation on Windows 2022.

- Tableau Server 2021.3.0 and later:
 - Windows Server 2016
 - Windows Server 2019

Earlier versions:

- Tableau Server 2020.1.0 - 2021.2.x:
 - Windows Server 2012
 - Windows Server 2012 R2
 - Windows Server 2016
 - Windows Server 2019
- Tableau Server 2019.1.0 - 2019.x:
 - Windows Server 2008 R2
 - Windows Server 2012

Tableau Server on Windows Help

- Windows Server 2012 R2
- Windows Server 2016
- Windows Server 2019

Note: All nodes in a multi-node cluster must have the same type of operating system. You cannot install a multi-node instance of Tableau Server on a combination of Linux and Windows nodes.

Installation directory

By default, Tableau Server will install on the system drive. The drive where Windows is installed is the system drive. In most cases, the system drive is the C:\ drive. In this default case, Tableau Server will install into the following directories:

- `C:\Program Files\Tableau\Tableau Server\packages`
- `C:\ProgramData\Tableau\Tableau Server`

Do not specify a symbolic link or a data directory location on a Network File System (NFS) volume.

Non-default installation locations

Rather than install onto the system drive, some organization install applications on a separate drive. During setup (or with automated installation), you can specify a different installation location. If you select a different installation drive or folder location during setup, then the data directory for Tableau Server will install into the same path. This means that if you install to a non-default location, the default `C:\ProgramData\Tableau\Tableau Server` path will not be created.

When you install to a non-default location, you must take the following into consideration:

- You may need to configure Run As service account permissions manually. If you do not use the predefined local account, NetworkServices, as the Run As service account, then you will need to set permissions for the account that you will be using. You must set these permissions after you install Tableau Server. See [Verify Folder Permissions](#).
- Log files are stored at `<installation path or drive>\data\tabsvc\logs`. The `C:\ProgramData\Tableau\Tableau Server\data\tabsvc\logs` path in a default installation is converted to `<installation path or drive>\data\tabsvc\logs`.
- You may need to specify the same location when you upgrade to newer versions of Tableau Server. For more information on upgrading, see [Upgrade Tableau Server Overview](#).

Note: If you run Tableau Server on a VM, either locally, or in the cloud, be aware of the potential for complications related to licensing. This applies whether you are running Tableau Server as a standalone or in a cluster. If you are simply upgrading Tableau Server on the VM, you do not need to take any extra action related to licensing. If you plan to clone the VM to create either a new production or test environment to upgrade, you need to deactivate any Tableau Server licenses before cloning. If you do not do this, the new VM environment can end up with an untrusted license, and any attempts to upgrade will fail.

To clone a VM, make sure the Tableau Server is unlicensed (all licenses are deactivated). After cloning the VM, activate the Tableau license on the cloned VM and proceed with the upgrade.

- When installing a multi-node instance of Tableau Server, the installation location (path) must be the same on every node.

Tableau Prep Conductor

Tableau Prep Conductor is one of the process on Tableau Server. It runs a flow, checks connection credentials, and sends alerts if a flow fails. Tableau Prep Conductor leverages the

scheduling and tracking functionality of Tableau Server so you can automate running flows to update the flow output instead of logging into Tableau Prep Builder to manually run individual flows as your data changes.

Tableau Prep Conductor is licensed separately and is available through the Data Management license. For more information on Tableau Prep Conductor licensing, see [License Data Management](#).

We recommend you enable Tableau Prep Conductor on a dedicated node. For more information:

- If you are installing a new Tableau Server, see [Step 1 \(New Install\): Install Tableau Server with Tableau Prep Conductor](#).
- If you are adding Tableau Prep Conductor to an existing installation of Tableau Server, see [Step 1 \(Existing Install\): Enable Tableau Prep Conductor](#).

Additional requirements

Make sure that your environment also meets the following additional requirements:

Hostname

- Tableau Server must be able to resolve the hostname to an IP address either using the domain name server (DNS) or with a local host file on the computer running Tableau Server. By default, host files are stored at `\Windows\System32\Drivers\etc\hosts`.
- The hostname of the server must not change after you start Tableau Services Manager during the setup process. For example, this might happen if you use the cloud-init package to initialize a virtual machine, and you install Tableau Server on that virtual machine.
- Hostnames that include underscores (`_`) are not supported by Tableau Server.

Static IP address

The computer where you install Tableau Server must have a static IPv4 or IPv6 address.

If both IPv4 and IPv6 are enabled or multiple network cards (NICs) are being used, unexpected behavior can result. For more information, see the following:

- **For Tableau Server deployments running on Windows Server 2019:** Changes to Windows Server 2019 IPv6 configuration behavior can result in IPv6 taking precedence over IPv4. To verify IPv6 precedence, review the [Tableau Server IPs changed and not all TSM services are coming up correctly](#) article in the Tableau Knowledge Base and update your computer settings.
- **When multiple NICs are being used:** In deployments where multiple NICs are used, review Troubleshoot Inconsistent Process Status for best practices.

Database drivers

To connect to specific data sources, the computer where you install Tableau Server must have the correct database drivers installed. For more information, see Database Drivers.

Available ports

TSM and Tableau Server each require an available TCP port in order for you to access them. TSM defaults to port 8850, and the Tableau Server Gateway service defaults to port 80. We strongly recommend that you ensure that both port 8850 and 80 are not in use on your system before installing Tableau Server. If those ports are not available, the TSM and gateway ports may be dynamically remapped to different port numbers, and there is currently no interface for displaying which port they have been remapped to.

If you are installing Tableau Server on a computer that's also running IIS (not a recommended deployment), you should modify the Tableau's gateway port number to avoid conflict with IIS. You can specify a different gateway port number during the setup process.

See Tableau Services Manager Ports.

Local firewall configuration

If you are running a firewall on the computer where you will be installing Tableau Server, then you will need to open the following default ports for Tableau Server traffic. All port numbers, except 443 can be changed.

Port	TCP/UDP	Used by ...	TYPE OF INSTALLATION	
			All	Distributed / High Availability
80	TCP	Gateway	X	
443	TCP	SSL. When Tableau Server is configured for SSL, the application server redirects requests to this port. Do not change this port.	X	
8850	TCP	Tableau Services Manager.	X	
8060	TCP	PostgreSQL database.	X	
8061	TCP	PostgreSQL backup verification port	X	
8000-9000	TCP	Range of ports reserved by default for dynamic mapping of Tableau processes		X
27000-27009	TCP	Range of ports used by Tableau Server for License service. This range must be open on the node running the License service and accessible from other nodes. By default, the initial node runs the License service.	X	

See Tableau Services Manager Ports

For information about configuring the local Windows firewall, refer to the Microsoft product documentation.

Local administrator

The account that you use to run Setup must be a member of the Local Administrators group on the Windows computer where Tableau Server is installed.

By default, you must also use an account with local administrator rights to run Tableau Services Manager (TSM) Web UI and CLI tools. However, after you have installed Tableau Server, you can specify a Windows group for TSM administration. See [Configure a Custom TSM Administration Group](#).

Use TSM to configure the Tableau Server components that rely on OS-level access, such as processes, authentication, log files, licensing, and alerts. See [TSM Authentication](#).

Tableau-specific administration, such as importing users, creating sites, web authoring, etc. is performed by Tableau Server administrators. You can configure these administrative accounts by assigning roles to users after you install. The initial Tableau Server administrator account is created as part of the installation process. See [Add an Administrator Account](#).

Run As service account

A Run As service account for the Tableau Server service to run under is useful if you're using NT Authentication with data sources or if you're planning on doing SQL Server impersonation. For more information, see [Run As Service Account and SQL Server Impersonation](#).

In some organizations, Group Policy or other system management solutions are used to standardize permissions and accounts on application servers. If your organization runs a such a solution, be sure to configure the system to accommodate the folder permissions required by the Run As service account. See [Verify Folder Permissions](#).

Antivirus software

Antivirus software that scans directories used by Tableau Server can interfere with installation and ongoing use of Tableau Server. In some cases, this can result in installation failures, problems starting Tableau Server, or impacts to performance. If you plan to run antivirus software on the computer running Tableau Server, follow the recommendations in the [Knowledge Base](#).

Continue to the next step: [Install and Configure Tableau Server](#).

Disk Space Requirements

In general, when estimating the amount of additional disk space to allocate for Tableau Server for day-to-day usage, you must consider whether or not extracts will be published to Tableau Server, and consider the number of workbooks that you expect to publish to Tableau Server. If you anticipate using extracts, Tableau recommends that you begin with a few hundred gigabytes (GB). If you do not anticipate using extracts, you may only need around 50 GB to fulfill your usage needs. To setup drive space alerts, see [Configure Server Event Notification](#).

Looking for Tableau Server on Linux? See [Disk Space Requirements](#).

It is critical for Tableau Server to have adequate disk space. If you run out of disk space on any node in a Tableau Server installation, you can experience erratic performance, including not being able to access Tableau Server or the TSM Web UI. For troubleshooting steps, see [Troubleshoot Disk Space Usage on Tableau Server Nodes](#) in the Tableau Knowledgebase.

Here are the factors that affect disk space requirements and where you might choose to install Tableau Server:

Drive size and type of partition

The type of partition used on your Tableau Server drive can impact the amount of space available to your Tableau Server installation.

- Master Boot Record (MBR) partitions support partitions and hard drives up to 2 terabytes (2T) and can be used on boot drives.
- GUID partition table (GPT) partitioning support partitions and hard drives up to 18 exabytes in size but cannot be used on boot drives. These are a good choice when installing Tableau Server on an additional drive because they provide for so much disk space, allowing enterprises to scale up over time.

Publishing extracts to Tableau Server

Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.

Refreshing extracts

Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.

Creating many workbooks

If using workbooks, consider the number of workbooks that will be published to Tableau Server. Individual workbooks tend to take up a small amount of disk space. However, if you anticipate thousands of workbooks being published, you may want to allocate additional disk space to accommodate those workbooks.

Logging

To assist with daily management and troubleshooting, Tableau Server creates log files as a part of its normal operations. Depending on the level at which the logging is configured, it can significantly impact the amount of disk space necessary on the Tableau Server computer.

Backup and restore processes

The free disk space required to create a backup varies depending on the amount of data in the Tableau Server repository and file store services, and their collocation with the tabadmincontroller service. During backups, the background tasks for cleaning up old extracts are temporarily paused. This means that, for the duration of the backup, extract refreshes will leave extra files in place, adding to disk space usage. If your backup takes a long time, or if your organization uses many extracts that are regularly updated, this can result in a

significant amount of temporary disk space usage. These temporary files will be removed after the backup is complete.

The following table lists the disk space requirements for backup based on whether the node hosts the repository, file store, controller, or some combination of them. In multi-node Tableau Server environments you need to estimate the required disk space on each node.

Repository	File Store	Controller	Disk Space Required
✓			<p>3x repository data + 250 MB</p> <p>To obtain an estimate of the repository data, check the size of <data directory>/pgsql/data/base directory.</p> <p>To obtain the exact size of the repository data, open the backup file and use the size of the workgroup.pg_dump file.</p>
	✓		<p>1.5x file store data</p> <p>To obtain an estimate of file store data (extracts, flows, etc.), check the size of <data directory>/dataengine directory.</p>
		✓	3x repository data + 250 MB + 2.5x file store data
✓	✓		3x repository data + 250 MB + 1.5x file store data
	✓	✓	3x repository data + 250 MB + 1.5x file store data

✓		✓	3x repository data + 250 MB + 2.5x file store data
✓	✓	✓	3x repository data + 250 MB + 1.5x file store data

Restore disk space requirements

You must have adequate disk space for the database restore process to run successfully.

To restore Tableau Server:

- On controller nodes, you need free space equal to at least the size of the backup archive.
- On repository nodes, you need free space equal to at least three times the size of the repository data in the backup archive, plus 250 MB, plus the size of the postgresql data directory.
- On file store nodes, you need free space equal to at least twice the size of the dataengine folder in the backup archive.

Recommended Baseline Configurations

Determining the topology (number of nodes, number of Tableau Server processes) of your Tableau Server deployment requires you to consider these variables: your environment, sources of data and management to provide self-service data access, workload, and usage. However you may not have enough information about these variables when you deploy Tableau Server for the first time. This topic describes three baseline architectures that can be used as starting points for your Tableau Server installations.

Validating your server deployment plan

Before you commit to installing a new Tableau Server deployment in your organization, be sure to carefully evaluate your options. For most organizations, Tableau Cloud will provide a more reliable, performant, and cost-effective analytics solution when compared to self-

hosting Tableau Server. For information about the viability of Tableau Cloud for your organization, review this blog post, [Should I move my analytics to the cloud?](#)

Already running Tableau Server and want to migrate to Tableau Cloud? See [Tableau Cloud Manual Migration Guide](#).

If you have determined that you must self-host Tableau Server, we recommend following the prescribed Tableau deployment in the [Enterprise Deployment Guide](#) (EDG). The EDG presents a fully-tested and supported, performant, scalable, secure reference architecture based on a tiered data network. Moving forward, we are committed to investing in the EDG reference architecture to ease feature rollouts and improve upgrade scenarios.

Hardware recommendations for production installations

The hardware recommendations for production Tableau Server installations below are based on the hardware that the Tableau team uses to test Tableau Server scalability. We suggest that you use these recommendations as starting points for your production deployments. For Proof of Concept (PoC) deployments, we recommend you use Tableau Cloud. For more information, see Minimum installation hardware requirements.

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
Single node	<ul style="list-style-type: none"> • 64-bit (x64 chipsets) • Must support SSE4.2 and POPCNT instruction sets • ARM-based processors are not supported 	8 cores (16 vCPUs), 2.0 GHz or higher	Version 2022.3 and later: <ul style="list-style-type: none"> • 128 GB Version 2021.4.0 to version 2022.1.x: <ul style="list-style-type: none"> • 64 GB Version 2021.3.x and earlier:	500 GB - 1 TB

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
			<ul style="list-style-type: none">• 32 GB	
		If you are adding Tableau Prep Conductor to your Tableau Server installation, we recommend you add a second node and dedicate this to running Tableau Server Prep Conductor. This node should have a minimum of 4 cores (8 vCPUs), and 16 GB of RAM.		
Multi-node and enterprise deployments	Contact Tableau for technical guidance. Nodes must meet or exceed the minimum hardware recommendations, except: <ul style="list-style-type: none">• Dedicated Backgrounder nodes running up to two instances of backgrounder, where 4 cores may be acceptable.• Dedicated node for Tableau Prep Conductor: Minimum of 4 cores (8 vCPUs), and 16 GB of RAM.• Dedicated node for Independent Gateway: Minimum of 2 cores (4 vCPUs), 8 GB of RAM, and 100 GB free disk space.			

Note: For deployments using virtual machines, Tableau recommends dedicated CPU affinity. If you are running Tableau Server in a virtual environment, use your VM host's best practices for vCPU allocation in relation to the number of physical CPU cores on the VM host. Typically 2 vCPUs = 1 physical core for Tableau Server. For example, for AWS installations, the 4 core minimum recommendation is equivalent of 8 AWS vCPUs. Similarly, follow the best practices provided by your virtual infrastructure provider to make sure Tableau Server has access to the appropriate compute, memory, and data resources. If you are installing Tableau Server in a virtual environment or a cloud-based deployment, see Virtual Machines and Public Cloud Deployments section later in this topic.

Estimating Disk Space

There are several factors that affect disk space requirements, including whether or not you will be publishing extracts, flows, and the number of workbooks to Tableau Server. For more information see [Disk Space Requirements](#).

Baseline Configurations

- Single Server Installations
- Two Node Installation - Specialized for extract heavy environments
- Two Node Installation - Specialized for flow environments
- High Availability Installations (HA)

Single Server Installations

Recommendations

We recommend using a single machine to install Tableau Server for initial deployments with limited usage and are not mission critical. Single Server installations can also be expanded to multi-node installation as your workloads grow.

Here are some instances when a single server installation may not be right for you:

- If your system is considered mission critical and needs to be highly available. High availability is about minimizing the system downtime. It is achieved by eliminating single points of failure, and having a reliable failover mechanism. Tableau Server requires a minimum of a three-node configuration to provide redundancy and eliminate the single points of failure. This is one of the primary reasons to move to a multi-node configuration.
- If you have a lot of active users and a lot of extract refreshes, the two types of loads may be competing for the same resources on the machine. In such a scenario, a single server configuration may not be the right option as you may need additional specialized nodes to isolate the different workloads.

Note: Active users represent the interactive, concurrent requests made to Tableau Server, including consuming dashboards on a laptop or mobile device, web authoring, and connecting to and querying Published Data Sources.

- Stand-alone single server node with all the processes installed on one machine.
- By default Tableau Server installer configures the number of process instances based on the hardware on the machine. We recommend that you keep the default configuration as your starting point. Below are the number of processes for an 8 core machine.
 - VizQL Server: Set to 2 instances (default calculation: Number of physical cores divided by 4, up to a maximum of 4).
 - Backgrounder, Cache Server, and Data Server: Set to 2 instances.
 - All other processes, only one instance of the process is installed, regardless of hardware.

Note: One instance of Tableau Prep Conductor is automatically configured with Backgrounder, when you have the Data Management Product Key activated on your server. However, It is recommended that you have a dedicated node for Tableau Prep Conductor. If you plan to have flows on your Tableau Server, we recommended you use two or more nodes and dedicated one of these nodes to run only flows. The example configuration described above does not include Tableau Prep Conductor since it is a single node server.

Multi-Node Installations

Running Tableau Server on more than one machine is called a multi-node installation, or a cluster. There are various reasons why you might want to have a multi-node installation. For example, you may have heavy extract environments which can mean dedicating some hardware resources to Backgrounder process. For systems that have high availability requirements, you need a multi-node environment that has at least three nodes.

Two Node Installation - Specialized for extract heavy environments

Recommendations

Start with a two node configuration when the following conditions apply to you:

- **Extract heavy environment:** Majority of your data sources are extracts. Having just a few, extremely large extracts could put your deployment in this category, as would having very many small extracts.
- **Frequent extract refreshes:** Refreshing an extract is a CPU-intensive task. Deployments where extracts are frequently refreshed (for example, several times a day during business hours) are often helped by more emphasis on the background process, which handles refresh tasks.

Important: Two-node configurations do not meet the minimum requirements for high availability. If you need a system that is highly available, see High Availability Installations (HA).

Tableau Server on Windows Help

- On the initial node, install all the processes except for the backgrounder. Below is the number of instances of the processes for an 8 core machine:
 - VizQL Server: Set to 2 instances. (default calculation: Number of physical cores divided by 4, up to a maximum of 4).
 - Cache Server, and Data Server: Set to 2 instances. One instance of Ask Data is automatically configured on the node that has Data Server.
 - Index and Search Server : Index and Search Server memory can be configured to improve performance by using the `indexandsearchserver.vmopts` TSM configuration option. For more information, see [tsm configuration set Options](#).
 - All other processes, only one instance of the process is installed, regardless of hardware. One instance of Interactive Microservice Container is installed on a node that has Application Server enabled, and one instance of Non-Interactive Microservice Container is installed on a node that has Backgrounder enabled.
- Isolate backgrounder on the additional node. To calculate the minimum number of backgrounder processes to run on this node, divide the computer's total number of physical cores by 4. To calculate the maximum number, divide the computer's total physical cores by 2. In the example shown above, both the nodes are on machines with 8 physical cores. When you install the backgrounder, Tableau Server automatically installs one instance of the Data Engine.

Note: This configuration assumes that you do not have Tableau Prep Conductor enabled on your Tableau Server. If are using Tableau Prep Conductor to schedule and manage flows, and have an extract heavy environment, we recommend that you have at least 3 nodes and use the 3 node configuration described later in this topic.

As you monitor and gather data about the performance and usage, you can fine tune and configure the number of instances for these processes. For example, on the node dedicated to running backgrounder you can initially set the number of backgrounders to the recommended

minimum (total number of cores divided by four), and increase the number of backgrounder processes later if you find that:

- Extract refreshes are taking a long time to complete
- Subscriptions and alerts are not completing on time

For dedicated backgrounder nodes, depending on workload and system resources, you may be able to increase the number of backgrounder instances beyond the maximum recommended above. Increasing backgrounder instances on the node can impact node functionality in positive and negative ways. You are responsible for carefully monitoring RAM and CPU resources, and other aspects of Tableau Server to determine the best configuration for your environment.

For more information on performance tuning, see [Performance Tuning](#) topic.

Two Node Installation - Specialized for flow environments

Start with a two node configuration if you are planning to publish, schedule, and manage flows on your Tableau Server.

Important: Two-node configurations do not meet the minimum requirements for high availability. If you need a system that is highly available, see [High Availability Installations \(HA\)](#).

- On the initial node, install all the processes. Below is the number of instances of the processes for an 8 core machine:
 - VizQL Server: Set to 2 instances. (default calculation: Number of physical cores divided by 4, up to a maximum of 4).
 - Cache Server, and Data Server: Set to 2 instances. One instance of Ask Data is automatically configured on the node that has Data Server.
 - Backgrounder: Minimum 2, maximum 4. The diagram above shows the maximum for an 8 core node. Tableau Prep Conductor is automatically configured on the node where you have backgrounder installed. On the initial node, set the Backgrounder node role to run all job types including flows using the `tsm topology set-node-role` tsm configuration. For more information, see [tsm topology set-node-role](#)
 - Index and Search Server: Index and Search Server memory can be configured to improve performance by using the `indexandsearchserver.vmopts` TSM configuration option. For more information, see [tsm configuration set Options](#).
 - All other processes, only one instance of the process is installed, regardless of hardware. One instance of Interactive Microservice Container is installed on a node that has Application Server enabled, and one instance of Non-Interactive Microservice Container is installed on a node that has Backgrounder enabled.
- Isolate the backgrounder on the additional node to run only flows. Use the `tsm topology set-node-role` tsm configuration to configure this setting. For more information, see [tsm topology set-node-role](#)

Note: If you have both a heavy extract environment, and schedule and manage flows on your server, we recommend that you use the 3 node configuration described below.

High Availability Installations (HA)

Recommendations

A highly available installation of Tableau Server is a distributed installation that is designed to maximize the availability of Tableau Server. High availability basically means that the system is available with minimal amount of downtime. To build in redundancy for HA related items such as repository, file redundancy, and failover, you need a **minimum of three nodes**. The tolerance for downtime will vary for each organization and depends on the SLAs you have established in your organization.

High availability is achieved by eliminating single points of failure and detecting failures and setting up a reliable failover system. HA in Tableau Server is mainly achieved by:

- File redundancy with multiple File Store/Data Engine instances.
- Active/Passive Repository across two nodes.
- Index and Search Server across all the three nodes.
- Adding an external load balancer to make sure your installation is robust to Gateway failures and make sure that requests only get routed to functioning Gateway processes.

Server Configuration

Three-node configuration:

- To build in redundancy, you need to add additional nodes to host instances of the repository and File Store/Data Engine processes. You can add instances of other processes, including multiple instances of a process on a node.

- To build redundancy for the type of backgrounder jobs, have one of the nodes (initial node in this example) run all type of jobs. Backgrounders run all types of jobs by default. On one of the additional nodes, set the backgrounder to run only flows, and the other additional node to run all jobs except for flows.
- The successful functioning of Tableau Server depends on a properly functioning Coordination Service. For server installations of three or more nodes, we recommend that you add additional instances of the Coordination Service by deploying a new Coordination Service ensemble. This provides redundancy and improved availability in the event that one instance of the Coordination Service has problems. For more information, see [Deploy a Coordination Service Ensemble](#) .
- Index and Search Server memory is added to all three nodes for redundancy and can be configured to improve performance by using the `index-andsearchserver.vmopts` TSM configuration option. For more information, see `indexandsearchserver.vmopts`.
- To reduce the system's vulnerability, you can run multiple gateways and additional instances of some of the server processes. The fewest number of computers required to achieve this configuration is three.
- The repository has also been moved from the initial node to one of the additional nodes, and a second, passive instance has been added to the other new node.
- One instance of Interactive Microservice Container is installed on a node that has Application Server enabled, and one instance of Non-Interactive Microservice Container is installed on a node that has Backgrounder enabled.

NOTE: In certain circumstances you may want to limit the processes running on your initial node. Reasons for doing this include wanting to run as few processes as possible on the node to limit processing requests on the node. You might also remove licensed Tableau Server processes from the node if you have a core-based license and do not

want the initial node cores to count against your core use. For more information on Tableau Server licensed processes, see [Tableau Server Processes from the node](#).

Virtual Machines and Public Cloud Deployments

In general, the considerations and recommendations described in this topic apply to virtual environment and cloud deployments.

If you are running Tableau Server in a virtual environment, use your VM host's best practices for vCPU allocation in relation to the number of physical CPU cores on the VM host. Typically 2 vCPUs = 1 physical core for Tableau Server. For example, for AWS installations, the 4 core minimum recommendation is equivalent of 8 AWS vCPUs.

For more information on cloud-based deployments, see:

- [Self-Host Tableau Server in a Public Cloud Service](#).

Beyond Baseline Configurations

If you are planning a system whose configuration is beyond the limits documented here, contact [Tableau Professional Services](#).

High VizQL Peak Usage Considerations

For optimal performance for Tableau Server we recommend isolating the repository on a dedicated node in your deployment. If you have an Advanced Management license, consider running the repository as an external database.

If your organization has a peak load of more than 1000 VizQL sessions per hour, we also recommend running Tableau Server on Linux. In this scenario, VizQL sessions refer to any user actions that display or generate visualizations from Tableau Server.

For more information, see [Tableau Server External Repository](#).

Disaster Recovery Considerations

While HA configurations reduce downtime, you may still encounter failures in case of a disaster or hardware failures. In addition to the above considerations, you should evaluate the importance of disaster recovery in your organization and plan for a deployment that helps you meet your disaster recovery goals and objectives.

When planning for disaster recovery (DR) in your Tableau environment, there are two main factors to consider:

- Recovery Time Objective (RTO), a measure of how much downtime your business can accept before a full recovery.
 - Influences how often you restore your backups to an alternative cluster and the amount of infrastructure investment.
- Recovery Point Objective (RPO), a measure of how much data loss your business can tolerate.
 - Influences how often you will need to take backups of your system.
 - For Tableau Server the RPO cannot be shorter than the time it takes to complete a full backup of your server.

The diagram below illustrates how to plan for a range of RTO requirements:

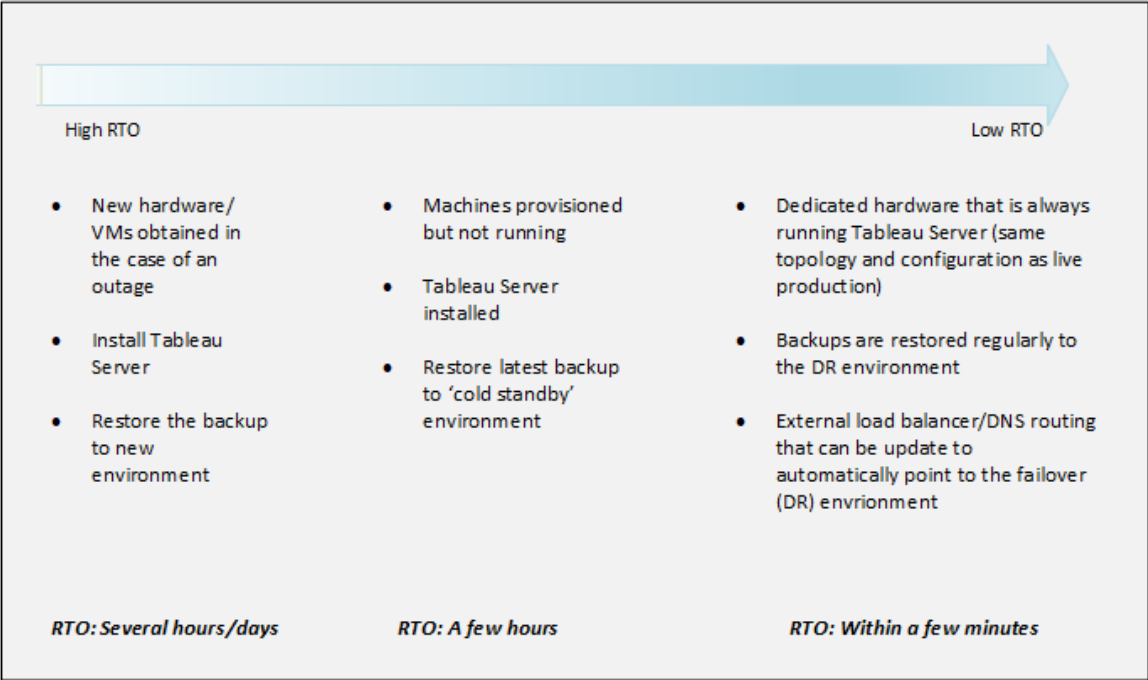

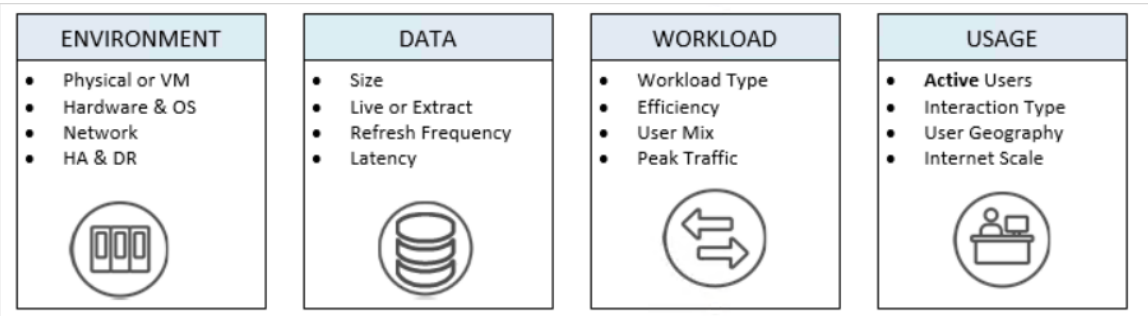

Tableau Server Scalability

These baseline configurations may not be enough as your needs change and grow, and you might need to scale your Tableau Server beyond these configurations. Like other enterprise platforms, Tableau Server scales up by adding processor, memory, and disk to existing node, and scales out by adding more nodes to a cluster. However, scalability and performance are heavily dependent on external systems and user activity. The configuration of your Tableau Server can be different depending on your requirements and variables:

For more information on Tableau Server scalability and the variables affecting scalability, see [Tableau Server Scalability whitepaper](#).

Run As Service Account

The *Run As* service account is a Windows account that Tableau Server uses ("runs as") when it accesses resources. For example, Tableau Server reads and writes files on the computer where Tableau Server is installed. From the perspective of Windows, Tableau Server is doing this as the Run As service account. In some cases, Tableau Server may use the Run As service account to access data from external sources, such as databases or files on a shared network directory.

As you plan your Tableau Server deployment, you need to determine if the default Run As service account, configured to run under the context of the local Network Service account (NT Authority\Network Service), will suffice for your needs. If it does not, then you will need to update the Run As service account to run under a domain account that has access to the resources in your Active Directory domain(s).

In either case, it's important to understand the security implications of the account that Tableau Server uses for the Run As service account. Specifically, if Tableau Server needs to access other servers, file shares, or databases that use Windows authentication, then the account that is configured for Run As service account will be used to access those resources. The account that is configured for Run As service account must also have elevated permissions to the local Tableau Server. A general best security practice is to limit the scope of all user accounts to the minimum required permissions. We make the same recommendation to you as you plan Run As service account. For more information, see [Data Access with the Run As Service Account](#)

The account you use for the Run As service account should not be a member of the Local Administrators or Domain Administrators account. Instead we recommend using a domain user account that is not an administrator for the Run As service account. Using a domain account that is not a member of these administrator groups is a good security practice and can help avoid access to certain data sources and folders. For information on best practices when creating a Run As service account, see [Creating the Run As service account](#).

You can set the Run As service account during Tableau Server installation, or you can update the Run As service account using the TSM Web UI. Tableau Services Manager sets

permissions for the Run As service account, but if you are unsure if the account you want to use for Run As service account satisfies the requirements, or if you have changed the Run As service account and are getting permission errors, see [Required Run As Service Account Settings](#).

Default Run As service account: Network Service

The Network Service account is a predefined local account with limited permissions that exists on all Windows computers. While it has limited administrative access to the local computer on which it runs, it does have more access to resources than members of the Active Directory default Users group. For example the Network Service group can write to the registry, the event log, and has special rights to log on for application services.

By default, the Run As service account is set to a local account called Network Service. Use the default Network Service account when:

- You are using local authentication for Tableau Server.
- All users in your organization include extracted data in the workbooks that they are uploading to Tableau Server.
- You are running Tableau Server in a single-server deployment.
- External data sources that your users access through Tableau Server do not require Windows NT integrated security or Kerberos. In most data-access scenarios, Microsoft

SQL Server, MSAS, Teradata, and Oracle databases require Windows NT integrated security.

While the Network Service account can be used to access resources on remote computers within the same Active Directory domain we do not recommend using the default account for such scenarios. Instead, configure a domain account for Run As service account if Tableau Server must connect to data sources in your environment. See [Change the Run As Service Account](#).

Run As service account: Domain user

For all Active Directory scenarios, we recommend updating the Tableau Server Run As service account with a domain user account. Update the Run As service account to a domain user account when data sources accessed through Tableau Server require Windows NT integrated security or Kerberos.

If you have deployed a distributed deployment of Tableau Server, then you can update the Run As service account with either a domain user or a Windows workgroup user. In either case, you must use the same user account for all server nodes. See [Distributed Requirements](#) for more information.

To configure your environment to use a domain account, see [Change the Run As Service Account](#).

Data Access with the Run As Service Account

When Windows Authentication is configured, the Run As service account requires read and query permissions to the databases that are accessed by Tableau Server. As designed, Run As service account permissions result in access to the same databases by Tableau Server users with the *Creator* role or the *Explorer (Can Publish)* role. Users with these roles can access and view the databases with the same level of access as the Run As service account when connecting to the databases using Windows Authentication option on Tableau Server.

For example, a user with the Creator role can view all databases that have been granted access to the Run As service account.

If the Creator-user specifies the database host name and selects Windows Authentication when creating a new data source from a web browser, then the user will be able to view the databases that have been permissioned for the Run As service account.

View access to database assets are not restricted to users who connect to Tableau Server with a web browser. Sophisticated users, who have the same roles noted above and who have knowledge of database server names, can also craft workbooks with Tableau Desktop that can view the databases that have been permissioned for the Run As service account.

The functionality described here is universal for all data sources that are accessed by the Run As service account, regardless of how users authenticate with Tableau Server. For example, even if users authenticate to Tableau Server with Kerberos or SAML, their access to all Run As-configured data sources will be the same. Users with Creator or Explorer (Can Publish) are able to access all data that is permissioned for the Run As service account.

Recommendations

Whether user access to databases in these scenarios is acceptable must be assessed by your organization. Generally, reducing the usage and scope of the Run As service account will reduce the likelihood of inadvertent user access to database content. However, reducing the usage and scope of the Run As service account may also impose more credential management to you and your users.

Evaluate the following recommendations in context of your business needs and data access policies.

- Firstly, be sure that you trust all users who have Creator roles or Explorer (Can Publish) roles. You will rely on these users to perform actions in Tableau with integrity.
- If you cannot trust all of your users who have publishing rights on data sources that are accessed by the Run As service account, then you should consider embedding credentials for those data sources.
- If a data source is not set up for automated extract refreshes, that is, the data source is primarily accessed as a live connection, then you may be able to use Kerberos Delegation. For requirements, see Enable Kerberos Delegation.

Configure Data Source Connection Settings

To automatically authenticate your users when the workbook they're accessing connects to a live, Windows-authenticated data source, configure your Tableau data connection with the **Use Windows Authentication** option selected:

Windows Authentication	Username and Password
Authenticates with the server's Run As user service account	Each Tableau Server user is prompted for database credentials
<div><div>Microsoft SQL Server</div><div>Server: <input type="text" value="mssql.example.com"/></div><div>Database: <input type="text" value="Optional"/></div><div>Enter information to sign in to the database:</div><div><div><input checked="" type="radio"/> Use Windows Authentication (preferred)</div><div><input type="radio"/> Use a specific username and password:</div></div><div><div>Username: <input type="text"/></div><div>Password: <input type="password"/></div></div><div><div><input type="checkbox"/> Require SSL</div><div><input type="checkbox"/> Read uncommitted data</div></div><div>Initial SQL...</div></div>	<div><div>Microsoft SQL Server</div><div>Server: <input type="text" value="mssql.example.com"/></div><div>Database: <input type="text" value="Optional"/></div><div>Enter information to sign in to the database:</div><div><div><input type="radio"/> Use Windows Authentication (preferred)</div><div><input checked="" type="radio"/> Use a specific username and password:</div></div><div><div>Username: <input type="text" value="jsmith"/></div><div>Password: <input type="password" value="••••••••"/></div></div><div><div><input type="checkbox"/> Require SSL</div><div><input type="checkbox"/> Read uncommitted data</div></div><div>Initial SQL...</div><div>Sign In</div></div>

It's important to understand how the Run As service account accesses data on behalf of the users in your organization. In some cases, users may inadvertently access data that their

users accounts are not explicitly permissioned for. Before allowing users to access data with the Run As service account, review Data Access with the Run As Service Account.

Change the Run As Service Account

Depending on your environment and data access requirements, you may want or need to change the Run As service account. There are two main scenarios where you change the Run As service account:

- Replacing the default Run As local account (NetworkService) with a domain account. If you are operating in an environment where a majority of your data sources are authenticated in the context of Active Directory (Windows NT integrated security) then you will need to configure the Run As service account to use a domain account, not the local account (NetworkService).
- Changing an existing domain Run As service account to a different account.

This topic describes both scenarios and describes how to update the Run As service account password.

The account you use for the Run As service account should not be a member of the Local Administrators or Domain Administrators account. Instead we recommend using a domain user account that is not an administrator for the Run As service account. Using a domain account that is not a member of these administrator groups is a good security practice and can help avoid access to certain data sources and folders. For information on best practices when creating a Run As service account, see [Creating the Run As service account](#).

Replacing the default Run As local account (NetworkService) with a domain account

If you are going to replace the default NetworkService account with a domain account, we recommend using a dedicated account for the Run As service account. Follow these steps:

1. Create the Run As service account in Active Directory
2. Configure Tableau Server to use the Run As service account

Creating the Run As service account

Follow these best practices:

- It's important to understand how the Run As service account accesses data on behalf of the users in your organization. In some cases, users may inadvertently access data that their users accounts are not explicitly permissioned for. Before you create a Run As service account, review Data Access with the Run As Service Account.
- Create a dedicated account in Active Directory for the Tableau Server Run As service account. In other words, don't use an existing account. By using a dedicated account you can be sure that the data resources that you permission for Tableau Server are only accessible by Tableau Server Run As service account.
- The Run As service account is used to query users and group membership in Active Directory. By default, the NetworkServices account and default domain users have permission to query Active Directory. Do not restrict read or query permissions for the Run As service account.
- Do not use an account with any kind of domain administrative permissions. Specifically, when you create an account in Active Directory, create an account in the domain User Group. Do not add the account that you create to any Active Directory security groups that needlessly elevate the permissions for the account.
- Permission the data sources in your directory for this one account. The account that you'll use for Run As service account only needs Read access to the appropriate data sources and network shares.
- If users in your organization authenticate with smart cards, disable the smart card logon option for the Run As service account.
- If you have installed Tableau Server on a drive other than the system drive, then you will need to configure the system drive to allow the Run As service account additional permissions. The system drive is the drive where Windows is installed. For example, if you have installed Windows on the C:/ drive, then C:/ is your system drive. If you install Tableau Server on any other drive (D:/, E:/, etc), then you will need to configure permissions for the Run As service account on the system drive. See [Required Run As Service Account Settings](#) for more information.

Configuring the Run As service account in Tableau Server

After you have created the Run As service account in Active Directory, configure Tableau Server to use that account.

Use the TSM Web UI to configure the Run As service account for the first time.

To configure the Run As service account

1. Open TSM in a browser:

<https://<tsm-computer-name>:8850>. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Security** tab, and then click the **Run As Service Account** tab.
3. Select **User Account** and then enter the user name and password for the service account. Specify the domain name as `domain\account`, where domain name is the NetBIOS name of the domain where the user resides:

The screenshot shows the 'Run As Service Account' configuration window. It has three tabs: 'Run As Service Account', 'External SSL', and 'Repository SSL'. The 'Run As Service Account' tab is active. Inside this tab, there are two radio buttons: 'NT AUTHORITY\NetworkService' and 'User Account'. The 'User Account' radio button is selected. Below the radio buttons are two text input fields: 'Username' and 'Password'. The 'Username' field contains the text 'EXAMPLE\runas-user' and the 'Password' field contains a series of dots. At the bottom of the window, there are two buttons: 'Cancel' and 'Save'.

4. Click **Save** to verify the user name and password.
5. When you are finished, click **Pending Changes**, and then click **Apply Changes and Restart**.

After you update the Run As service account, Tableau Server will automatically configure permissions on the local computer for the account that you have entered.

Changing an existing domain Run As service account to a different account

To change an existing domain Run As service account to a different account, you must apply permissions to that new account. To apply permissions to your new Run As service account,

you must first reset permissions by applying them to the default NetworkService account.

Before you begin, verify that the new account that you will be using for the Run As service account complies with the best practices noted previously in the section, Creating the Run As service account.

This procedure requires you to restart Tableau Server services twice, so run this procedure during off hours.

Use the TSM web interface

1. Open TSM in a browser:

<https://<tsm-computer-name>:8850>. For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the **Security** tab, and then click the **Run As Service Account** tab.
3. Under **User Account**, select **NT Authority\NetworkService**.
4. Click **Save**.
5. When you are finished, click **Pending Changes**, and then click **Apply Changes and Restart**.
6. After the server restarts, open TSM and navigate to the **Run As Service Account** tab.
7. Select **User Account** and then enter the user name and password for the service account. Specify the domain name as `domain\account`, where domain name is the NetBIOS name of the domain where the user resides:

Run As Service Account External SSL Repository SSL

Run As Service Account

☐ NT AUTHORITY\NetworkService

☒ User Account

Username Password

EXAMPLE\runas-user

Cancel Save

8. Click **Save** to verify the user name and password.
9. When you are finished, click **Pending Changes**, and then click **Apply Changes and Restart**.
10. Revoke the permissions for the previous account. See Revoke Run As Service Account Permissions.

Use the TSM CLI

1. Reset the Run As service account to NetworkService. Run the following command:

```
tsm configuration set -k service.runas.username -v "NT
AUTHORITY\NetworkService"
```

2. Run the following command to save this change and restart:

```
tsm pending-changes apply
```

3. Set the Run As service account to the new account. Run the following commands:

Tableau Server on Windows Help

```
tsm configuration set -k service.runas.username -v <domain\user-  
name>
```

```
tsm configuration set -k service.runas.password -v "<password>"
```

Enclose the password with double quotes to ensure special characters in the string are processed correctly. To view the password as it will be stored, run the following command:

```
tsm pending-changes list
```

The password will be validated with Active Directory. If valid, then the password will be encrypted and saved. TSM will not report success or failure.

4. Run the following command to save and restart:

```
tsm pending-changes apply
```

Troubleshooting:

- Verify that the server has started. If it is in a degraded state, then you may have entered an incorrect password. View the stored password by running the `configuration get` command. This command will decrypt and display the password in the shell. Run the following command:

```
tsm configuration get -k service.runas.password
```

If the previous password is displayed, then you did not enter a valid password.

- Enter the correct password (see Step 3), and then run the following command to save and restart:

```
tsm pending-changes apply
```

5. Revoke the permissions for the previous account. See [Revoke Run As Service Account Permissions](#).

Updating the Run As service account password

If the Run As service account password has been updated in Active Directory you must update it for Tableau Server. The Run As service account password is encrypted and stored on Tableau Server. For more information, see [Manage Server Secrets](#).

If you are running Tableau Server in a distributed deployment, then you only need to update the password with TSM on the initial node in the cluster. TSM will distribute this configuration to each node automatically.

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Security** tab, and then click the **Run As Service Account** tab.
3. Under **User Account**, enter the password for the service account.
4. Click **Save** to verify the password.
5. When you are finished, click **Pending Changes**, and then click **Apply Changes and Restart**.

Use the TSM CLI

1. Set the new password. Run the following command:

```
tsm configuration set -k service.runas.password -v "<password>"
```

Enclose the password with double quotes to ensure special characters in the string are processed correctly. To validate that special characters were escaped correctly, run the following command to view the password as it will be stored:

Tableau Server on Windows Help

```
tsm pending-changes list
```

The password will be validated with Active Directory. If valid, then the password will be encrypted and saved. TSM will not report success or failure.

2. Run the following command to save and restart:

```
tsm pending-changes apply
```

Troubleshooting:

- Verify that the server has started. If it is in a degraded state, then you may have entered an incorrect password. View the stored password by running the `configuration get` command. This command will decrypt and display the password in the shell. Run the following command:

```
tsm configuration get -k service.runas.password
```

If the previous password is displayed, then you did not enter a valid password.

- Enter the correct password (see Step 1), and then run the following command to save and restart:

```
tsm pending-changes apply
```

Troubleshooting: Update the password in the Microsoft Services console

In some cases, you may see service failures after updating the Run As service account password. If so, then you may need to manually update the password for the **Tableau Server Services Manager** service. Update the password in the Microsoft Services management console.

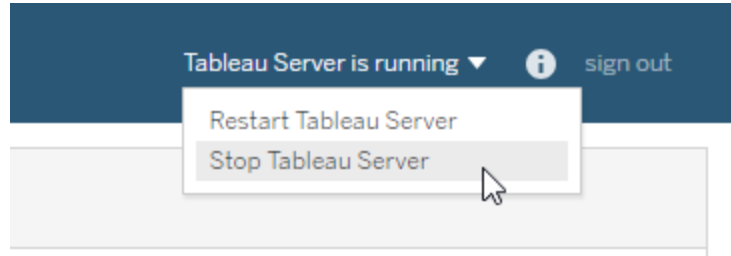

If you are running Tableau Server in a distributed deployment, then you must perform the following procedure on each node in the cluster.

1. Stop Tableau Server.

- To use the TSM CLI, run the following command:

```
tsm stop
```

- To use the TSM Web UI, on the top-right of the page, click the drop-down list next to the status, and then click **Stop Tableau Server**:

2. Open the Services MMC snap-in on the Windows computer that is running Tableau Server.
3. Double-click the **Tableau Server Services Manager** service to open the properties page.
4. On the **Tableau Server Services Manager Properties** page, click the **Log On** tab, and then enter the password for the service account.
5. Click **Apply**, then click **OK**.
6. Restart the **Tableau Server Services Manager** service by right-clicking on the service name and then clicking **Restart**.
7. Start Tableau Server.

- To use the TSM CLI, run the following command:

```
tsm start
```

- To use the TSM Web UI, on the top right of the page, click the drop-down list next to the status, and then click **Start Tableau Server**.

Related tasks

The Run As service account is central to many operations on Tableau Server, especially those that are involved with remote data access. To avoid access errors, review the tasks here and follow the links for those that apply to your scenario.

- If you are running Tableau Server in an organization with multiple Active Directory domains, see [Domain Trust Requirements for Active Directory Deployments](#).
- Enabling Kerberos single sign-on requires additional configuration related to the Run As service account. To enable Kerberos single sign-on with Tableau Server, see [Kerberos](#).
- Enabling impersonation requires additional configuration related to Run As service account. To deploy and enable impersonation with Microsoft SQL Server, see [Impersonate with Embedded SQL Credentials](#).
- If you have installed Tableau Server onto the non-system drive, then you will need to manually set some permissions for the Run As service account. See [Required Run As Service Account Settings](#) for more information.
- If you have changed the Run As service account, then we recommend revoking the permissions for the previous account. See [Revoke Run As Service Account Permissions](#).
- If your organization uses a forward proxy solution, then you may need to reconfigure the local LAN settings on the Tableau Server with the Run As service account. See [Configure a forward proxy server](#) for more information. In this scenario, the Run As service account must also be temporarily configured as the log on account for Tableau Server Administrative Controller for product key operations. See [Configure Product Key Operations with Forward Proxy](#).
- If you are using the Resource Monitoring Tool in your enterprise, the Run As service account may be used to authenticate and gather Hardware information. When updating a Run As account, confirm connectivity between RMT and Tableau Server in the RMT Environment Settings:
 1. Sign into RMT as an administrator.
 2. Navigate to the Environments page (Admin > Environments).
 3. Click **Edit** for the environment that was updated.
 4. In the **Servers** list, confirm that each server shows the Agent Service as Connected. Hover over the Connected status to see a timestamp of the last heartbeat message received.

Troubleshoot Run As User

As discussed in the topic, [Run As Service Account](#), Tableau Server requires administrative-like access to the machine on which it is installed. Therefore, when you update the Run As service account, a background process will configure permissions on the Tableau computer for that account. However, in some complex deployment scenarios you may need to verify or manually configure the Run As service account permissions on the local Tableau Server computer. Use this section to verify how permissions are configured on the machines running Tableau Server in your deployment. This section also includes procedures that describe how to set permissions and configure security policies for the Run As service account.

Required Run As Service Account Settings

The Run As service account needs permissions that allows it to modify files and registry settings. In addition, because the Run As service account is used as the security context for the Tableau Server Application Manager service (tabsvc), the account must also be given rights to log on as a service.

These permissions are set automatically when you update the Run As service account in Tableau Server Configuration as described in the topic, [Change the Run As Service Account](#).

If you have changed the Run As service account, then we recommend revoking the permissions for the previous account. See [Revoke Run As Service Account Permissions](#).

The account you use for the Run As service account should not be a member of the Local Administrators or Domain Administrators account. Instead we recommend using a domain user account that is not an administrator for the Run As service account. Using a domain account that is not a member of these administrator groups is a good security practice and can help avoid access to certain data sources and folders. For information on best practices when creating a Run As service account, see [Creating the Run As service account](#).

If you have recently changed Run As service account or are getting permission errors, use this section to confirm that Tableau Server meets the permission requirements that are

detailed here. If you're running a distributed installation, all Run As service account permission configurations must be the same across all nodes.

Note: Do not hide the files created by the Tableau Server installer.

Verify Folder Permissions

The account the Tableau Server service runs under is referred to as the Run As service account. The Run As service account needs permission to specific folder resources on the Windows computer.

This topic provides:

- An accounting of the permissions that are required by the Run As service account.
- Information about installing Tableau Server in non-default locations.
- How to reapply permissions on an existing Run As service account using TSM.

This topic refers to the drive where Windows is installed as the *system drive*. The system drive is equivalent to the Windows environmental variable, %WINDIR%. The drive where Tableau Server is installed is referred to as the *install drive*.

Resource	System or install drive	File Path	Permissions required
folder	system	SYSTEMROOT:\windows\system32	Read, List folder contents
executable	system	SYSTEMROOT:\windows\system32\cmd.exe	Read & execute
Drive root	install	root, for example, Local Disk (C:)	Read, List folder contents
folder	install	PROGRAMFILES\Tableau\Tableau Server	Modify

folder	install (on system drive)	\ProgramData\Tableau\Tableau Server\	Modify
folder	install (on non- system drive)	\Tableau\Tableau Server\data\	Modify

When you update the Run As service account in TSM, a background process will configure the folder permissions on the Tableau computer for the Run As service account that you specify.

In this case, where you are installing on the system drive into the default folder (C:\Program Files\Tableau), the configuration of folder permissions will be handled by TSM. You do not need to verify or change any folder permissions for this scenario. If you install Tableau Server onto a different drive, you will need to manually configure some permissions.

Installing in a non-default location

If you are installing Tableau Server in a non-default location on a different drive, then you will need to configure permissions on the installation folder for Run As service account as well as the predefined local accounts: Network Service, Local Service, and System.

The following table describes the permissions that are applied if you install Tableau Server in a non-default location. All of these permissions are set on the installation folder, and are inherited by the subfolders and files in the installation folder. These permissions are configured by the Tableau Setup program and are also reconfigured whenever you upgrade Tableau Server to a new version. Changing permissions on these folders may impair functionality.

For more information about different accounts used by Tableau Server, see [Windows Accounts and Permissions](#).

Set permissions for this account:	Permissions required
The user account that is used to install and upgrade Tableau Server	Full control
The user account that is used to run TSM commands	Full control
System account	Full control
Run As service account, Network Service, and Local Service	Read & execute

Reapplying folder permissions

In some organizations, Group Policy or other system management solutions are used to standardize permissions and accounts on application servers. If your organization runs a such a solution, be sure to configure the system to accommodate the folder permissions required by the Run As service account. If the folder permissions for the Run As service account have been changed, you can use TSM to reapply the permissions. See [Changing an existing domain Run As service account to a different account](#).

Verify Registry Permissions

The account the Tableau Server service runs under needs permission to modify the registry on the local machine.

In a multi-node cluster, the registry permissions are only granted on the tsm node in the cluster.

When you update the Run As service account, TSM will configure the registry permissions on the Tableau computer for the account you specify. It's unlikely that you will need to apply these permissions manually.

Verify that the Run As service account has been granted permissions to the `HKEY_LOCAL_MACHINE\Software\Tableau` registry branch. If the account that you have specified as the

Run As service account is a member of the local administrative group or a member of the Domain Admins security group, then the account will not be displayed on the Permissions page.

Permissions

TSM will grant Read permission and the following Special permissions to these branches:

- Query Value
- Set Value
- Create Subkey
- Enumerate Subkeys
- Notify
- Write DAC
- Write Owner
- Read Control

To view or edit permissions on registry directories:

1. Open the Registry Editor by entering `regedit` in Windows Run, and then clicking **OK**.
2. In Registry Editor, navigate to the directory where you want to view or edit permissions. Right-click the directory, and then click **Permissions....**
3. In Permissions, on the Security tab, select the Run As service account, and then click **Advanced**.
If you are adding your Run As service account, then click **Add** and follow the Windows process for adding a user account to the Security tab. After you have added the account, then select the Run As service account, and then click **Advanced**
4. In Advanced Security Settings. on the Permissions tab, select the Run As service account, and then click **Edit**.
5. On the Permission Entry, under Basic permissions, verify that **Read** and **Special permissions** are selected. Verify that **Only apply these permissions to objects and/or containers within this container** is not selected.
6. To view or edit Special permissions, click **Show advanced permissions**.
7. Under Advanced permissions, verify that the permissions enumerated at the beginning of this topic are selected. Verify that **Only apply these permissions to objects and/or containers within this container** is not selected.

8. If you have set new permissions, then click **OK** through the multiple windows to finish. If you have viewed permissions and not edited anything, then click **Cancel** to close all windows.

Verify the Local Security Policy

After you specify a Run As service account in Tableau Services Manager (as described in the topic, [Change the Run As Service Account](#)), TSM will update the local security policy on the computer running Tableau Server. TSM will update the local security policy to give "log on as a service" and "log on locally" permissions to the Run As service account. This elevated policy is required because the Run As service account is used as the security context for the Tableau Server Application Manager service (tabsvc).

Note: If the Run As service account that you specify in TSM is a member of the local administrators or a domain administrator, then TSM may not update the local security policy. Updating the Run As service account with an account that is a member of local administrators or domain administrators is not a good security practice. We recommend using a domain User account for the Run As service account.

In some cases, you may need to manually set security policy for your Run As service account. For example, some organizations run Windows Group Policy that remove "Log on as a service" or "Allow log on locally" rights that have been set on user accounts. Or an organization may run a policy that creates a permission conflict by specifying "Deny log on as a service." If your organization does this, then you will need to disable or edit such Group Policies so that your Run As service account is not affected. For details on best practices when creating a Run As service account, see [Creating the Run As service account](#).

The following procedure describes how to configure security policies, **Log on as a service** and **Allow log on locally**, manually. You can also use the procedure below to verify that your Run As service account is appropriately configured with local security policy rights. For example, you should verify that the Run As service account is not specified on the **Deny log on as a service** policy.

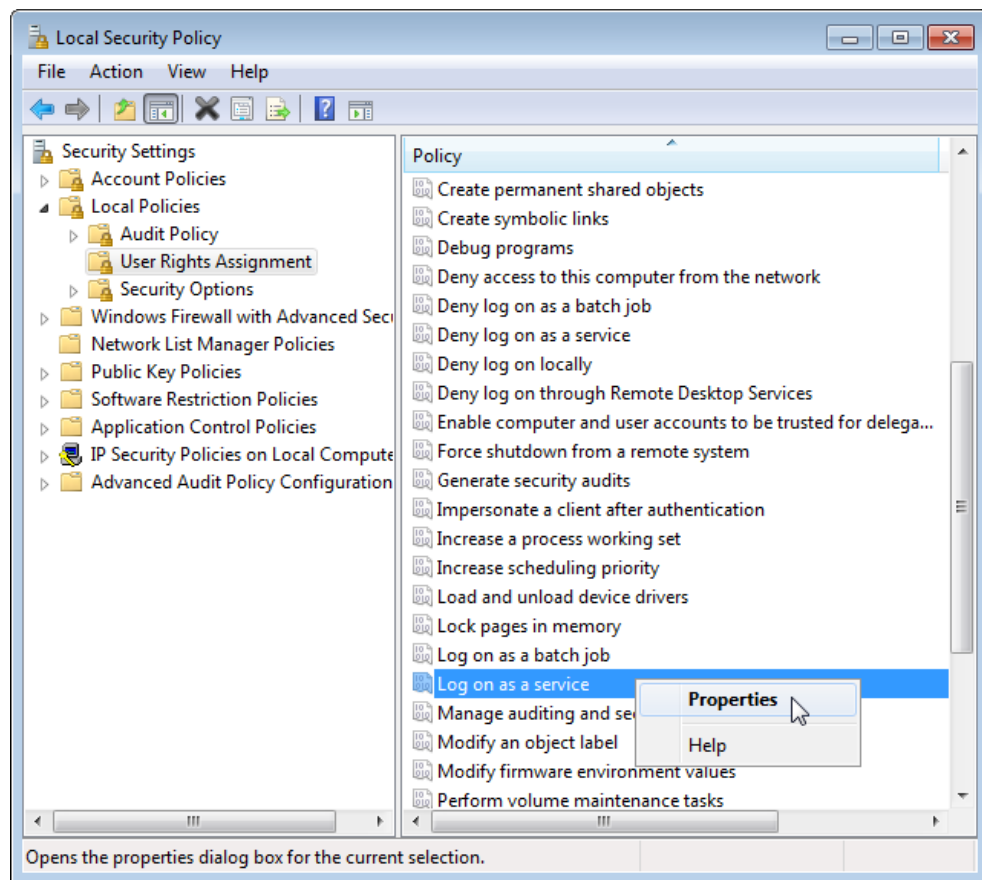

If you are running a distributed installation, then configuration must be the same across the initial and all additional nodes.

To verify or update the local security policy:

1. Select **Start > Control Panel > Administrative Tools > Local Security Policy**.
2. In Local Security Policy, open **Local Policies**, select **User Rights Assignments**.

To verify or set Log on as a service policy:

- a. Right-click **Log on as a service** policy and then click **Properties**.

- b. In **Log on as a service Properties**, click **Add User or Group**.
- c. Type the <domain>\<username> for the Tableau Server Run As service account (for example: MYCO\tableau_server), and click **Check Names**.
- d. When the account resolves correctly, it is underlined. Click **OK**.

To verify or set Allow log on locally policy:

- a. Right-click **Allow log on locally** policy and then click **Properties**.
- b. Verify that the Run As service account is specified. If it is not, follow the procedure above to add the Run As service account.

To verify Run As service account is not specified in the Deny log on as a service policy:

- a. Right-click **Deny log on as a service** policy, and then click **Properties**.
 - b. In **Deny log on as a service Properties**, verify that the Run As service account is not listed. If it is, remove it. When you are finished, click **OK**.
3. Click **OK** to close the Local Security Settings windows.

Verify Tableau Service Settings

Confirm that Tableau services are assigned the correct Log On and Startup values. If you are running a **distributed installation** of Tableau Server, perform these steps on all nodes in the cluster.

Note: The Startup Values for TSM services changed in these maintenance releases: 2020.215, 2020.3.10, 2020.4.6, and 2021.1.3. Values changed from "Automatic" to "Automatic (Delayed Start)" for the following TSM services: Tableau Server Administration Agent, Tableau Server Administration Controller, Tableau Server Client File Service, Tableau Server Coordination Service, Tableau Server License Manager, and Tableau Server Service Manager. If you are running older versions of Tableau Server you do not have to change these values from "Automatic" but can do so without negative impact.

1. Log on as administrator to the computer running Tableau Server.
2. On the Tableau Server computer, select **Start > Control Panel > Administrative Tools > Computer Management > Services and Applications > Services**.
3. Open Services and Applications, then click **Services**. Confirm that the following services have the correct settings:

Service Name	Logon Value	Startup Value
FLEXnet Licensing Service 64	Local System	Automatic
Secondary Logon	Local System	Manual
Tableau Server Administration Agent	Local System	Automatic (Delayed Start)
Tableau Server Administration Controller	Network Service	Automatic (Delayed Start)
Tableau Server Client File Service	Network Service	Automatic (Delayed Start)
Tableau Server Coordination Service	Network Service	Automatic (Delayed Start)
Tableau Server License Manager (Runs on initial node only)	Local Service The License Manager relies on default Windows folder permissions that are applied to the Local Service. In more secure environments, you must modify the permissions on the Tableau installation directory. Otherwise, you may encounter licensing errors. See Verify Folder Permissions for more information.	Automatic (Delayed Start)
Tableau Server Service Manager	<domain>\<username> This is the Run As service account. See below. If you	Automatic (Delayed Start)

Service Name	Logon Value	Startup Value
	have not specified a Run As service account, then the Network Service system account is used.	

Note: Do not change the default settings on the **Recovery** tab of the **Tableau Server Service Manager Properties** dialog box; leave the settings for failure recovery as **Restart the Service**.

Changing the Log On Value

To change the **Log On** value for Tableau Server (tabsvc) to the Run As service account, see [Change the Run As Service Account](#).

Revoke Run As Service Account Permissions

Changing the Run As service account in Tableau Server Configuration Utility does not remove the permissions from the previous account. Therefore, after you change the Run As service account, we recommend manually revoking permissions from the previous account as a secure best practice. Follow the procedure below to revoke permissions from the previous Run As service account.

If you have changed your Run As service account and your organization uses a forward proxy solution, then you may need to reconfigure the local LAN settings with the new Run As service account. See [Configure a forward proxy server](#) for more information.

You must be logged onto the Tableau Server computer with an administrator account to perform the following procedures.

Remove folder permissions

Tableau Server configures permissions on Windows folders according to the location where you install Tableau Server. Before you remove folder permissions, review [Verify Folder Per-](#)

missions to identify the resources for which you will need to remove permissions. Run the following procedure for each of the resources you have identified:

1. For each resource (drive, folder, executable), right-click the resource, and then click **Properties**.
2. On the resource property page, click the **Security** tab, and then click **Edit** to change permissions.
3. On the Permissions page, select the previous Run As service account and then click **Remove**.
4. Click **OK**.

Remove registry permissions

Remove the previous Run As service account from the following registry locations:

- HKEY_CURRENT_USER\Software\Tableau
- HKEY_LOCAL_MACHINE\Software\Tableau

Warning: Editing the Windows registry incorrectly can have harmful effects on your computer.

1. Open the Registry Editor by entering `regedit` in Windows Run, and then clicking **OK**.
2. For each registry directory, right-click the **Tableau** folder, and then click **Permissions**.
3. In the **Permissions for Tableau** page, select the previous Run As service account, and then click **Remove**.
4. Click **OK**.

Remove security policies

Remove the previous Run As service account from the following security policies:

- “Log on as a service” policy
 - “Allow log on locally” policy
1. Select **Start > Control Panel > Administrative Tools > Local Security Policy**.
 2. In **Local Security Policy**, open **Local Policies**, select **User Rights Assignments**.

3. For each policy:
 - a. Right-click the policy and then select **Properties**.
 - b. On the policy property page, select the previous Run As service account, and then click **Remove**.
 - c. Click **OK**.

Identity Store

Tableau Server requires an identity store to manage user and group information. There are two kinds of identity stores: local and external. When you install Tableau Server you must configure either a local identity store or an external identity store.

For information about configuration options for the identity store, see [identityStore Entity](#) and [External Identity Store Configuration Reference](#). For more information about adding more flexibility to the single identity store model, see [Provision and Authenticate Users Using Identity Pools](#).

Local identity store

When you configure Tableau Server with a local identity store, all user and group information is stored and managed in the Tableau Server repository. In the local identity store scenario, there is no external source for users and groups.

External identity store

When you configure Tableau Server with an external store, all user and group information is stored and managed by an external directory service. Tableau Server must synchronize with the external identity store so that local copies of the users and groups exist in the Tableau Server repository, but the external identity store is the authoritative source for all user and group data.

If you have configured the Tableau Server identity store to communicate with an external LDAP directory, then all users (including the initial admin account) that you add to Tableau Server must have an account in the directory.

When Tableau Server is configured to use an external LDAP directory, you must first import user identities from the external directory into the Tableau Server repository as system users. When users sign in to Tableau Server, their credentials are passed to the external directory, which is responsible for authenticating the user; Tableau Server does not perform this authentication. However, the Tableau user names stored in the identity store are associated with rights and permissions for Tableau Server. Therefore, after authentication is verified, Tableau Server manages user access (authorization) for Tableau resources.

Active Directory is an example of an external user store. Tableau Server is optimized to interface with Active Directory. For example, when you install Tableau Server on an Active Directory domain-joined computer using the Configure Initial Node Settings, Setup will detect and configure most Active Directory settings. If, on the other hand, you are using TSM CLI to install Tableau Server, you must specify all the Active Directory settings. In this case, be sure to use the LDAP - Active Directory template to configure identity store.

If you are installing into Active Directory, you must install Tableau Server onto a computer that is joined to the Active Directory domain. Additionally, we recommend that you review *User Management in Deployments with External Identity Stores* before you deploy.

For all other external stores, Tableau Server supports LDAP as a generic way to communicate the identity store. For example, OpenLDAP is one of several LDAP server implementations with a flexible schema. Tableau Server can be configured to query the OpenLDAP server. To do so, the directory administrator must provide information about the schema. During setup, you must use Configure Initial Node Settings to configure a connection to other LDAP directories.

LDAP bind

Clients that wish to query a user store using LDAP must authenticate and establish a session. This is done by binding. There are multiple ways to bind. Simple binding is authenticating with a username and password. For organizations that connect to Tableau Server with simple bind, we recommend configuring an SSL encrypted connection, otherwise the credentials are sent over the wire in plaintext. Another type of binding Tableau Server supports is GSSAPI

binding. GSSAPI uses Kerberos to authenticate. In Tableau Server's case, Tableau Server is the client and the external user store is the LDAP server.

LDAP with GSSAPI (Kerberos) bind

We recommend binding to LDAP directory with GSSAPI using a keytab file to authenticate to the LDAP server. You will need a keytab file specifically for the Tableau Server service. We also recommend encrypting the channel with the LDAP server using SSL/TLS. See [Configure Encrypted Channel to LDAP External Identity Store](#).

If you are installing into Active Directory, and the computer where you are installing Tableau Server is already joined to the domain, then the computer may already have a configuration file and a keytab file. In this case, the Kerberos files are for the operating system functionality and authentication. Strictly speaking, you can use these files for GSSAPI bind, but we don't recommend using them. Instead, contact your Active Directory administrator and request a keytab specifically for the Tableau Server service. See [Understanding Keytab Requirements](#).

Assuming your operating system has a properly configured keytab for authentication to the domain, then the Kerberos keyfile for GSSAPI bind is all you need for the base installation of Tableau Server. If you plan to use Kerberos authentication for users, then [configure Kerberos for user authentication](#) and [Kerberos delegation to data sources](#) after installation is complete.

LDAP over SSL

By default, LDAP with simple bind to arbitrary LDAP servers is not encrypted. User credentials that are used to establish the bind session with the LDAP server are communicated in plaintext between Tableau Server and the LDAP server. We strongly recommend that you encrypt the channel between Tableau Server and the LDAP server.

If your organization uses an LDAP directory other than Active Directory, see [Configure Encrypted Channel to LDAP External Identity Store](#).

Authenticating clients

Basic user authentication in Tableau Server is by username and password sign-in for both local and external user stores. In the local case, user passwords are stored as a hashed password in the repository. In the external case, Tableau Server passes the credentials to the external user store and awaits a response as to whether the credentials are valid. External user stores can also handle other kinds of authentication like Kerberos or SSPI (Active Directory only), but the concept is still the same, Tableau Server delegates the credentials or user to the external store and awaits a response.

You can configure Tableau Server such that username-password sign-in is disabled. In these scenarios other authentication methods, such as trusted authentication, OpenID, or SAML can be used. See [Authentication](#).

In some cases, you may need to update LDAP external directories to allow bind operations with username + DN format from Tableau Server. See [User binding behavior on sign in](#).

User Management in Deployments with External Identity Stores

This topic describes important technical details that you should be familiar with if you use an external identity store to manage users for Tableau Server. Tableau Server supports connecting to an external directory using LDAP. In this scenario, Tableau Server imports users from the external LDAP directory into the Tableau Server repository as system users.

Arbitrary LDAP directories

The system username in Tableau is whatever attribute you set as part of LDAP configuration, for example "cn". This is true for both individual user import and group sync functionality. See [External Identity Store Configuration Reference](#).

User binding behavior on sign in

You may need to update your LDAP configuration to allow binding with usernames appended with the DN. Specifically, you will need to update your LDAP configuration when Tableau

Server is configured with an arbitrary LDAP directory. (e.g., OpenLDAP) that uses UPN or Email addresses as usernames.

Tableau Server will search for a given user based on the username that is supplied during sign in. Tableau Server will then attempt to bind with the username appended with the DN. In the case where Tableau Server has been configured with GSSAPI, then the username@REALM (domain name) will be used.

Active Directory

This content in rest of this topic assumes that you are familiar with Active Directory user management and basic Active Directory schema and domain concepts.

If you are installing into Active Directory, you must install Tableau Server onto a computer that is joined to the Active Directory domain.

Note: In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

Active Directory user authentication and Tableau Server

Tableau Server stores all user names in the Tableau Server identity store, which is managed by the repository. If Tableau Server is configured to use Active Directory for authentication, you must first import user identities from Active Directory to the identity store. When users sign in to Tableau Server, their credentials are passed to Active Directory, which is responsible for authenticating the user; Tableau Server does not perform this authentication. (By default, NTLM is used for authentication, but you can enable Kerberos or SAML for single sign-on functionality—however, in all these cases, authentication is left to Active Directory.) However, the Tableau user names stored in the identity store are associated with rights and permissions for Tableau Server. Therefore, after authentication is verified, Tableau Server manages user access (authorization) for Tableau resources.

Active Directory user name attributes and Tableau Server

Active Directory uniquely identifies user objects using several attributes. (For details, see [User Naming Attributes](#) on the MSDN website.) Tableau Server relies on two Active Directory user naming attributes:

- `sAMAccountName`. This attribute specifies the logon name that was originally designed for use with older versions of Windows. In many organizations, this name is combined with the NetBIOS name for authentication, using a format like `example\j-smith`, where `example` is the NetBIOS name and `j-smith` is the `sAMAccountName` value. Due to the original design in Windows, the `sAMAccountName` value must be less than 20 characters.

In the Windows **Active Directory Users and Computers** administrative console, this value is in the field labeled **User logon name (pre-Windows 2000)** on the **Account** tab of the user object.

- `userPrincipalName` (UPN). This attribute specifies a user name in the format `j-smith@example.com`, where `j-smith` is the UPN prefix and `@example.com` is the UPN suffix.

In the Windows **Active Directory Users and Computers** administrative console, the UPN is a concatenation of two fields on the **Account** tab of the user object: the **User logon name** field, and the domain drop-down list next to it.

Adding users from Active Directory

You can [add users individually](#) from Active Directory, either by typing them in the server environment or by creating a CSV file and importing the users. You can also add Active Directory users by [creating a group via Active Directory](#) and importing all of the group's users. The result can be different depending on which approach you're using.

Importing UPN prefix as username

You cannot import the whole UPN as a user name.

In most cases, the user name that Tableau Server will import into the identity store will be the `sAMAccountName` value. For more information about exceptions to this behavior, see the [Importing UPN Prefix as Username in Non-Standard Scenarios with Active Directory](#) in the Tableau knowledge base.

Adding user groups

If you import an Active Directory user group, Tableau will import all users from the group using the `sAMAccountName`.

Sync behavior when removing users from Active Directory

Users cannot be automatically removed from Tableau Server through an Active Directory sync operation. Users that are disabled, deleted, or removed from groups in Active Directory remain on Tableau Server so that you can audit and reassign the user's content before removing the user's account completely.

However, Tableau Server will act upon user objects differently based how the status of that user object changes in Active Directory. There are two scenarios: deleting/disabling users in Active Directory or removing users from synchronized groups in Active Directory.

When you delete or disable a user in Active Directory and then synchronize that user's group on Tableau Server, the following occurs:

- The user is removed from the Tableau Server group you synchronized.
- The user's role is set to "unlicensed."
- The user will still belong to the All Users group.
- The user is unable to sign in to Tableau Server.

When you remove a user from a group in Active Directory and then synchronize that group on Tableau Server, the following occurs:

- The user is removed from the Tableau Server group you synchronized.
- The user's role is retained: it is not set to "unlicensed."
- The user will still belong to the All Users group.
- The user will still have permission to the Tableau Server with access to everything that the All Users group is granted permission to use.

In both instances, to remove a user from Tableau Server, the server administrator must delete the user from the Server Users page in Tableau Server.

Domain nicknames

In Tableau Server, domain nickname is equivalent to the Windows NetBIOS domain name. In a Windows Active Directory forest, a fully qualified domain name (FQDN) can have an arbitrary NetBIOS name. The NetBIOS name is used as the domain identifier when a user logs in to Active Directory.

For example, the FQDN `west.na.corp.lan` might be configured with a NetBIOS name (nickname) of `SEATTLE`. The user `jsmith` in that domain could log on to Windows using either of the following user names:

- `west.na.corp.example.com\jsmith`
- `SEATTLE\jsmith`

If you want your users to sign in to Tableau Server with a NetBIOS name instead of the FQDN, then you'll need to verify that the nickname value for each domain where users log in is set. See `editdomain` for information on how to view and set the nickname value for each domain.

Support for multiple domains

You can add users and groups from a domain that's different from the domain of the Tableau Server computer in these cases:

- Two-way trust has been established between the server's domain and the users' domain.
- The server's domain trusts the users' domain (one-way trust). See [Domain Trust Requirements for Active Directory Deployments](#).

The first time you add a user or group from the non-server domain, you must specify the fully qualified domain name with the user/group name. Any additional users or groups you add from that domain can be added using the domain's nickname, provided the nickname matches the NetBIOS name. If Tableau Server connects to multiple domains, you must also

specify the other domains that Tableau Server connects to by setting the `wgserver-domain.whitelist` (version 2020.3 and earlier) or `wgserver-domain.accept_list` (version 2020.4 and later) option with TSM. For more information, see `wgserver-domain.whitelist` or `wgserver-domain.accept_list`.

Duplicate display names

If user display names are not unique across multiple domains, then managing users with the same display name in Tableau can be confusing. Tableau Server will display the same name for two users. For example, consider an organization with two domains, `example.lan` and `example2.lan`. If user John Smith exists in both domains, then adding that user to groups and other administrative tasks will be confusing in Tableau Server. In this scenario, consider updating the display name in Active Directory for one of the users to differentiate the accounts.

Sign in to Tableau Server with NetBIOS name

Users can sign in to Tableau Server using the domain nickname (NetBIOS name), for example, `SEATTLE\jsmith`.

Tableau Server cannot query for NetBIOS name for a given FQDN. As a result, Tableau sets the nickname of a given FQDN according to the first entry in the namespace. For example, given the FQDN `west.na.corp.lan`, Tableau sets the nickname to `west`.

Therefore, you might need to update the domain nickname on Tableau Server before users can sign in using the nickname. If you do not update the nickname, users will have to sign in using a fully qualified domain name. For more information, see [Users From New Domain Unable to Log In and Do Not Appear in User List](#) in the Tableau Knowledge Base.

Domain Trust Requirements for Active Directory Deployments

When you run Tableau Server in an Active Directory environment across multiple domains (either in the same Active Directory forest or in different forests), some Tableau functionality is dependent on the trust relationship between the domains. For example, some administrators manage users in domains that are separate from where they deploy server applications, such as Tableau Server. In other organizations, a Tableau Server deployment might be shared with

external partners or with different partners in the organization. Finally, Windows-authenticated data sources, such as SQL Server, MSAS, or Oracle, that Tableau Server connects to may also be in other domains.

If it's feasible, we recommend configuring two-way trust between all domains that interact with Tableau Server. If this is not possible, Tableau Server can be configured to support user authentication where a one-way trust has been configured. In this case, a one-way trust between domains is supported when the domain in which Tableau Server is installed is configured to trust the domain where user accounts reside.

The following illustration shows one-way trust between the domain where Tableau Server is installed and the domain where user accounts reside:

In this scenario, Tableau Server is in the dev.local domain, and users from the users.lan Active Directory domain are imported into Tableau Server. A one-way trust is required for this scenario; specifically, the dev.local domain is configured to trust the users.lan domain. Users in the users.lan domain can access Tableau Server in the dev.local with their normal Active Directory credentials. However, you may need to update the domain nickname on Tableau Server before users log on with the nickname. Refer to the [Tableau Knowledge Base](#) for more information.

When you configure Tableau Server for this scenario, specify the primary user domain during installation. See [Configure Initial Node Settings](#). To ensure that Tableau Server can connect

to other Active Directory domains, you must also specify other domains that Tableau Server connects to by setting the `wgserver.domain.accept_list` option with TSM. For more information, see `wgserver.domain.accept_list`.

The Run As service account must also have query (Read) access to each domain from which users will be imported.

Kerberos single sign-on is supported in this one-way trust scenario.

Review [User Management in Deployments with External Identity Stores](#) to understand how multiple domains, domain naming, NetBIOS, and Active Directory user name format influence Tableau user management.

Connecting to live data in one-way trust scenarios

In the one-way trust scenario, users connecting to Tableau Server can connect to live data that's hosted in the cloud or on any other data source on premises that does not rely on Windows authentication.

Data sources that require Windows-authentication might have additional authentication requirements that complicate the scenario, or that can even prevent Tableau Server users from connecting. This is because Tableau Server uses the Run As service account for authentication with such data sources. If you are running Tableau Server in a different domain than data sources that use Windows authentication, verify that the Run As service account that is used for Tableau Server can access the data source.

Communicating with the Internet

In most enterprises, Tableau Server needs to communicate with the internet. Tableau Server was designed to operate inside a protected internal network. Do not set up Tableau Server directly on the internet or in a DMZ. Instead, communications between your network and the internet should be mediated using proxy servers. If the computer running Tableau Server cannot access the internet directly, then you may need to deploy forward proxy servers to mediate traffic from inside the network to targets on the internet. Tableau Server doesn't support pass-through or manual proxy authentication.

For inbound traffic, we recommend running Tableau Server behind reverse proxy servers.

How Tableau communicates with the internet

Tableau Server requires outbound access to the internet for these scenarios:

- Working with maps. Tableau uses map data that is hosted externally.

Tableau Server needs to connect to the following internet locations with port 443 to use maps:

- `mapsconfig.tableau.com`
- `api.mapbox.com`

If Tableau cannot make these connections, maps may fail to load.

You can test connectivity by accessing each of those addresses in a browser:

`https://mapsconfig.tableau.com/v1/config.json` and `https://api.mapbox.com/` will prompt you to download a json file.

If you use a proxy to connect to the internet and are unable to connect to `api.mapbox.com`, see [Working with firewalls](#) on the Mapbox website.

For Tableau Server version 2019.1 and earlier, see the documentation for your version: [Tableau Help](#)

- Connecting to the Tableau send-logs server.

You can upload log files to Tableau when working with Support. See `tsm maintenance send-logs`. To successfully upload files to Tableau, your Tableau Server must be able to communicate with the send-logs server on port 443:

`report-issue.tableau.com:443`

- Sending Basic Product Data.

Tableau Server on Windows Help

The domain, `prod.telemetry.tableausoftware.com`, is used by Tableau to receive the Basic Product Data about process launch and shutdown. It is also used for the more general Product Usage Data.

Traffic to this domain will occur on port 80 (for initial registration of our Product Data clients) and on port 443 (for all subsequent traffic).

`prod.telemetry.tableausoftware.com:80`

`prod.telemetry.tableausoftware.com:443`

- Licensing. Tableau products connect to the internet to activate product keys. Unless you activate Tableau software with the [Offline Activation Tool](#), all Tableau products must have access to the internet to validate licenses. Specifically Tableau requires internet access during the following licensing operations: activation, deactivation, and on the refresh maintenance date. For more information about these operations, see [Manage Licenses](#).

Tableau Server needs to connect to the following internet locations for licensing purposes:

- `atr.licensing.tableau.com:443`
- `licensing.tableau.com:443`
- `register.tableau.com:443`
- `o.ss2.us`
- `s.ss2.us`
- `crt.rootca1.amazontrust.com`
- `crt.sca1b.amazontrust.com`
- `crt.sca0a.amazontrust.com`

- crt.sca1a.amazontrust.com
- crt.sca2a.amazontrust.com
- crt.sca3a.amazontrust.com
- crt.sca4a.amazontrust.com
- *.digicert.com
- ocsp.*.amazontrust.com
- crl.*.amazontrust.com

Requests to the above domains may be on port 80 or 443. Port 80 is used for certificate validation (revocation, certificate chain, etc). Port 443 is used for SSL connections.

Requests to the `ocsp.*.amazontrust.com` and `crl.*.amazontrust.com` domains are managed by Amazon for certificate revocation information. See [ACM certificate characteristics](#) for more information.

If Tableau Server cannot make a connection while attempting to activate its license, you will be prompted to do an offline activation.

To diagnose connectivity to Tableau's licensing server, paste the following URL into a browser or at a curl command prompt on the Tableau Server computer:

```
https://atr.licensing.tableau.com/_status/healthz
```

If Tableau Server is able to access the licensing server, it displays an "OK" message. Otherwise, an error such as "Can't reach this page" may be displayed. To resolve this issue, work with your networking team to unblock access to `atr.licensing.tableau.com:443` on the Tableau Server computer.

Specifically, for deployments where ATR is configured, see Step 4: Verify proxy settings do not conflict with Windows environment variables.

- Working with external or cloud-based data.

Tableau Server needs to connect to the following internet location for Anaplan, Box, Dropbox, Google Drive, Google Sheets, OneDrive, and Snowflake services:

```
galop.connectors.tableau.com:443
```

- Working with Tableau dashboard extensions.

Tableau Server needs to connect to the following internet location to use Sandboxed dashboard extensions:

```
extensions.tableauusercontent.com: 443
```

For more information, see [Manage Dashboard Extensions in Tableau Server](#).

Tableau Server can run without internet access. For more information about deploying Tableau Server in organizations without access to the internet, see [Install Tableau Server in a Disconnected \(Air-Gapped\) Environment](#).

In many enterprises, users also need to access Tableau Server from outside the network (that is, from the internet). For example, in many enterprises, users want to be able to reach Tableau Server from their mobile devices in order to interact with views that are stored on the server. To configure access to Tableau Server from the internet or from mobile devices, you should use a reverse proxy. See [Configuring Proxies and Load Balancers for Tableau Server](#).

Configuring Proxies and Load Balancers for Tableau Server

In most enterprises, Tableau Server needs to communicate with the internet. Tableau Server was designed to operate inside a protected internal network. Do not set up Tableau Server directly on the internet or in a DMZ. Instead, communications between your network and the internet should be mediated using proxy servers. Forward proxy servers mediate traffic from inside the network to targets on the internet. Reverse proxy servers and load balancers mediate traffic from the internet to targets inside the network.

Who should read this article?

This article is for IT professionals who are experienced with general networking, load balancing, and gateway proxy solutions. The article describes how and when Tableau requires internet access, and describes how to configure your network and Tableau to use proxy servers and load balancers for access to and from the internet. There are many third-party solutions available, so some of the content in the article is necessarily generic.

Before you configure a proxy server, see [Communicating with the Internet](#).

Configure a forward proxy server

To enable communication from Tableau Server to the internet, deploy Tableau Server behind a forward proxy server. When Tableau Server needs access to the internet, it doesn't send the request directly to the internet. Instead, it sends the request to the forward proxy, which in turn forwards the request. Forward proxies help administrators manage traffic out to the internet for tasks such as load balancing, blocking access to sites, etc.

If you use a forward proxy, you must configure the computers that run Tableau Server inside the network to send traffic to the forward proxy. Tableau Server doesn't support pass-through or manual proxy authentication.

If you are running OpenID authentication with a forward proxy solution, additional configurations are required. See [Configure OpenID to work with a forward proxy](#).

Configuring Tableau Server on Windows to work with a forward proxy

The steps for configuring internet options on the Tableau Server computer depend on which of these scenarios describes your enterprise:

- **Your organization doesn't use a forward proxy solution.** If your organization is not running a proxy solution and the computer where you are installing Tableau Server can communicate with the internet, you don't need to follow the procedures here.

- **A proxy solution is deployed, and automatic configuration files define connection settings.** If your organization uses automatic configuration files (such as PAC or `.ins` files) to specify internet connection information, you can use this information in the Local Area Network (LAN) Settings dialog box in Windows. For more information, see [Enable Automatic Detection and Configuration of Browser Settings](#) on the Microsoft support site.
- **A proxy solution is deployed, but automatic configuration files are not deployed.** For this scenario, you must configure LAN settings on the Windows computer that is running Tableau Server so that connections to your proxy server are run under the security context of the Run As User account. You must also configure `localhost` and other internal Tableau Server instances as exceptions.

The following procedure describes the steps for the last scenario—a proxy solution without automatic configuration files, where Tableau Server is running on Windows Server.

Note: If you are using a distributed installation of Tableau Server, perform the following procedures on the initial server node and on each additional node.

Step 1: Add the Run As service account to the Local Administrators group

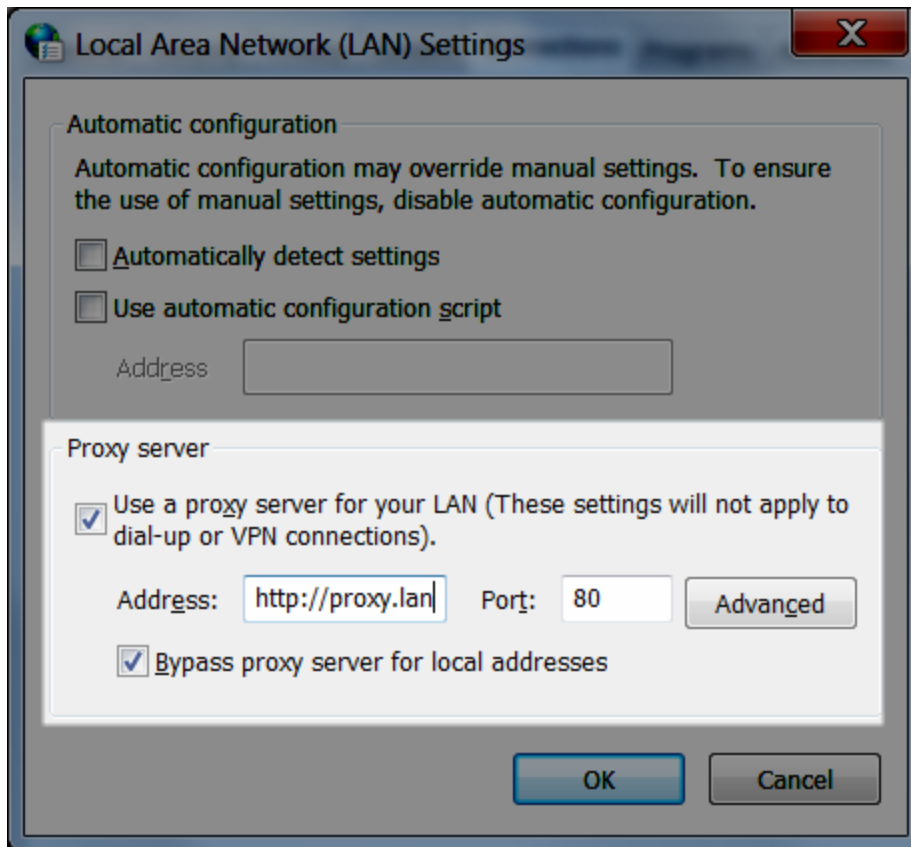

To perform this procedure, you must log onto the Tableau Server computer with the as the Run As service account. By default, the "log on locally" policy is not applied to the Run As service account. Therefore, you must temporarily add the Run As service account to the Local Administrators group.

If you haven't installed Tableau Server on the computer yet, see [Change the Run As Service Account](#). If you already installed Tableau Server and configured the Run As service account, then you can determine the Run As service account name by signing into TSM Web UI. The Tableau Server Run As service account is listed on the **Security** tab of the **Configuration** window. See [Sign in to Tableau Services Manager Web UI](#).

Add the Run As service account to the Local Administrators group using steps in [Add a member to a local group](#) on the Microsoft website. When you've finished configuring the forward proxy information, you'll remove the Run As service account from the Local Administrators group.

Step 2: Configure the proxy server in Windows LAN Settings

1. Using the Run As service account, log onto the computer where Tableau Server is installed or will be installed.
2. Open the **Local Area Network (LAN) Settings** dialog box. (A quick way to get to this dialog box is to search for `Internet Options` in the Windows Start menu. In the **Internet Properties** dialog box, click the **Connections** tab, and then click **LAN settings**.)
3. Under **Proxy server**, select **Use a proxy server for your LAN**, enter the proxy server address and port, and then select **Bypass proxy server for local addresses**.

Leave this dialog box open and continue to the next step.

Step 3: Add exceptions to bypass the proxy server

You add exceptions to this proxy configuration to guarantee that all communications within a local Tableau Server cluster (if you have one now or will have one later) do not route to the proxy server.

1. In the LAN settings dialog box, click **Advanced**. (This button is available only if you've selected the option to use a proxy server for your LAN.)
2. In the **Proxy Settings** dialog box, in the **Exceptions** field, enter the following:
 - `localhost`
 - Server host names and IP addresses of other Tableau Server computers in the same cluster.

Use semicolons to separate items.

3. Close the proxy settings dialog box and the Local Area Network (LAN) Settings dialog box.
4. In the **Internet Properties** dialog box, click **OK** to apply the settings.

Stay logged onto the computer and continue to the next step.

Step 4: Verify proxy settings do not conflict with Windows environment variables

Some organizations configure forward proxy settings as environment variables in the Windows operating system. If such settings are configured on the computer that is running Tableau Server, then you must verify that they do not conflict with the configurations you've completed here.

This verification is important if your Tableau Server is enabled for ATR licensing. ATR licensing is enabled by default on Tableau Server version 2021.4 and later.

1. On the computer that is running Tableau Server, enter "advanced system settings" in the search box and then click Enter to open the **System Properties** box.
2. On the **Advanced** tab, click **Environment Variables**.
3. Scroll through the **System variables** field.

If `http_proxy` or `https_proxy` are specified, verify that the values do not conflict with the proxy server address that you configured in the previous step.

- If the existing settings do not conflict, then go to "Step 5: Test the proxy configuration."
- If the existing settings do conflict, then create a new variable named `no_proxy`, and enter:

Tableau Server on Windows Help

- the host name,
- IP address

For example, `localhost`, `192.168.0.10`. For more information see the Microsoft MSDN article, [Set Environment Variables](#).

4. Click **OK**.

Step 5: Verify that the WinHTTP proxy settings do not conflict with Windows LAN settings

If Server ATR is enabled (it is enabled by default in Tableau Server 2021.4 or later), verify that the WinHTTP proxy is configured and does not conflict with Windows LAN Settings.

1. Using the Run As service account, log onto the computer where Tableau Server is installed or will be installed.
2. Open the command prompt and use the following command to confirm the current configuration:

```
netsh winhttp show proxy
```

3. Configure the proxy for WinHTTP using either of the following methods:

- Use the following command if you import the configuration from Windows LAN Settings:

```
netsh winhttp import proxy source=ie
```

- Use the following command to configure WinHTTP proxy separately:

```
netsh winhttp set proxy <proxy server> <proxy bypass list>
```

For more information see [Configure the proxy server manually using netsh command](#) at the Microsoft website.

4. Confirm that the proxy settings do not conflict with other Windows proxy configurations.

Step 6: Test the proxy configuration

To test the new configurations, while still logged in with the Run As service account on the Tableau Server computer, open a web browser and test the following Tableau URLs:

<https://mapsconfig.tableau.com/v1/config.json> and <https://api.mapbox.com/> will prompt you to download a json file.

Step 7: Remove the Run As service account from the Local Administrator group

After you have tested the proxy settings, remove the Run As service account from the Local Administrators group. Leaving the Run As service account in the administrator group elevates the permissions of the Run As service account and is a security risk.

Restart Tableau Server to ensure that all changes are implemented.

Server crash reporter

If your organization uses a proxy server to connect to the internet then you must configure Tableau Server's crash reporter to use the proxy. Even if you have already configured Tableau Server to use a proxy, you must also configure server crash reporter separately. To configure proxy for server crash reporter, see [Configure Server Crash Reporter](#).

How a reverse proxy and a load balancer works with Tableau Server

Reverse proxies and load balancers are servers that receive requests from external (internet) clients and forwards them to Tableau Server. These solutions make Tableau Server available to the internet without having to expose the individual IP address of that particular Tableau Server to the internet. They may also act as authentication and pass-through devices, so that no data is stored where people outside the company can get to it. This requirement can be important for organizations that are subject to various privacy regulations such as PCI, HIPAA, or SOX.

The following diagram illustrates the communication path when a client makes a request to Tableau Server that is configured to work with a reverse proxy and/or load balancer (LB).

1. An external client initiates a connection to Tableau Server. The client uses the public URL that's been configured for the reverse proxy server/LB, such as `https://tableau.example.com`. (The client doesn't know that it's accessing a reverse proxy/LB.)
2. The reverse proxy maps that request in turn to a request to Tableau Server. In some scenarios, the reverse proxy may be configured to authenticate the client (using SSL/TLS) as a precondition to passing the request to Tableau Server.
3. Tableau Server gets the request and sends its response to the reverse proxy/LB.
4. The reverse proxy/LB sends the content back to the client. As far as the client is concerned, it just had an interaction with Tableau Server, and has no way to know that the communication passed through intermediary server(s).

TLS/SSL

Depending on your gateway scenario, you should consider configuring your reverse proxy and load balancing servers to use TLS/SSL for any traffic that's external to your network. This helps to ensure privacy, content integrity, and authentication. Unless you've deployed other security measures to protect traffic between your internet gateway and Tableau Server, we also recommend configuring SSL between the gateway proxy and Tableau Server. You can use internal or self-signed certificates to encrypt traffic between Tableau Servers and other internal computers.

Mobile access

Tableau Server adds an X-header to all HTTP responses for Tableau Mobile sessions. By default, most proxy solutions will preserve X-headers. If your gateway solution does not preserve X-headers, then you will need to configure your proxy server and load balancer to preserve the following header to all HTTP responses for Mobile client sessions: `X-Tableau: Tableau Server`.

If you have configured authentication at the gateway, then your proxy server/LB must respond to Tableau Mobile HTTP requests with a HTTP 302 response. The 302 must include a redirect to the identity provider login page. To view a diagram that describes the 302 authentication sequence, see [Tableau Mobile Authentication Sequence](#) in the Tableau Community.

Reverse proxy, load balancer and user authentication

Tableau Server will always authenticate users. This means that even if you are authenticating inbound connections at the gateway for your organization, Tableau Server will still authenticate the user.

However, not all clients will support user authentication with a gateway solution:

- For supported web browsers, you can use SAML, OpenID Connect, Kerberos, Trusted Tickets or manual authentication with a reverse proxy/LB.
- Tableau Mobile supports SAML or manual authentication with a reverse proxy/LB. The iOS version of Tableau Mobile additionally supports Kerberos with a reverse proxy/LB. The same recommendation above applies.
- Tableau Prep does not support authentication with a reverse proxy or load balancer. For remote access, use a VPN solution or configure your gateway services to route traffic from Tableau Prep directly to Tableau Server for authentication.
- Tableau Desktop supports authentication with a reverse proxy provided that an authentication module is performing preauthentication on the reverse proxy before traffic is routed to Tableau Server for final authentication. For more information, see [Part 5 -](#)

Configuring Web Tier of the *Tableau Server Enterprise Deployment Guide* and Configure Authentication Module with Independent Gateway.

If your organization is authenticating with Active Directory:

- Active Directory with Enable automatic logon (SSPI) is not supported with a reverse proxy.
- Tableau Server must be configured for reverse proxy before configuring Tableau Server for Kerberos. For more information, see [Configure Kerberos](#).

Configure Tableau Server to work with a reverse proxy server and/or load balancer

Before you configure Tableau Server, you'll need to collect the following information about the proxy server configuration. To configure Tableau Server, you use the `tsm configuration set` command. The information you need to collect corresponds to options you'll need when you run `tsm`.

Most of the following `tsm` options are also used to configure Tableau Server deployments that operate behind a load balancer. For more information, see [Add a Load Balancer](#).

Item	Description	Corresponding <code>tsm configuration set</code> option
IP address or CNAME	<p>You can either enter an IP address or a CNAME for this option.</p> <p>The public IP address or addresses of the proxy and load balancer servers. The IP address must be in IPv4 format, such as <code>203.0.113.0</code>, and it must be a static IP.</p> <p>If you are unable to provide a static IP, or if you are using cloud proxies or external load balancers, you can spe-</p>	<code>gateway.trusted</code>

Item	Description	Corresponding <code>tsm</code> configuration set option
	<p>cify the CNAME (Canonical Name) DNS value that clients will use to connect to Tableau Server. This CNAME value must be configured on your reverse proxy solution to communicate with Tableau Server.</p>	
FQDN	<p>The fully qualified domain name that people use to reach Tableau Server, such as <code>tableau.example.com</code>. Tableau Server doesn't support context switching for this option. For example, the following URL is not supported: <code>example.com/tableau</code>.</p>	<code>gateway.public.host</code>
Non-FQDN	<p>Any subdomain names for the proxy or LB servers. In the example of <code>tableau.example.com</code>, the subdomain name is <code>tableau</code>.</p>	<code>gateway.trusted_hosts</code>
Aliases	<p>Any public alternative names for the proxy or LB servers. In most cases, aliases are designated using CNAME values. An example would be a proxy server <code>bigbox.example.com</code> and CNAME entries of <code>ftp.example.com</code> and <code>www.example.com</code>.</p>	<code>gateway.trusted_hosts</code>
Ports	<p>Port numbers for traffic from the client to the reverse proxy server.</p>	<code>gateway.public.port</code>

If you are using a distributed installation of Tableau Server, then run the following `tsm` commands on the initial node in your cluster.

Tableau Server on Windows Help

1. Enter the following command to set the FQDN that clients will use to reach Tableau Server through the proxy and/or LB servers, where *name* is the FQDN:

```
tsm configuration set -k gateway.public.host -v "name"
```

For example, if Tableau Server is reached by entering `https://tableau.example.com` in the browser, enter this command:

```
tsm configuration set -k gateway.public.host -v "tableau-  
.example.com"
```

2. Enter the following command to set the address or the CNAME of the proxy and or LB servers, where *server_address* is the IPv4 address or CNAME value:

```
tsm configuration set -k gateway.trusted -v "server_ip_address"
```

If your organization uses multiple proxy servers and/or LB servers, enter multiple IPv4 addresses, separating them with commas. IP ranges are not supported. To improve start up and initialization of Tableau Server, minimize the number of entries for `gateway.trusted`.

3. Enter the following command to specify alternate names for the proxy/LB servers, such as their fully qualified domain names, any not fully qualified domain names, and any aliases. If there's more than one name, separate the names with a comma.

```
tsm configuration set -k gateway.trusted_hosts -v "name1,  
name2, name3"
```

For example:

```
tsm configuration set -k gateway.trusted_hosts -v "proxyl.ex-  
ample.com, proxyl, ftp.example.com, www.example.com"
```

4. If the proxy server is using SSL to communicate with the internet, run the following command, which tells Tableau that the reverse proxy server is using port 443 instead of port

80:

```
tsm configuration set -k gateway.public.port -v 443
```

Note: If the proxy server is using SSL to communicate with Tableau Server, SSL must be configured and enabled on Tableau Server.

5. Enter the following command to commit the configuration change:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

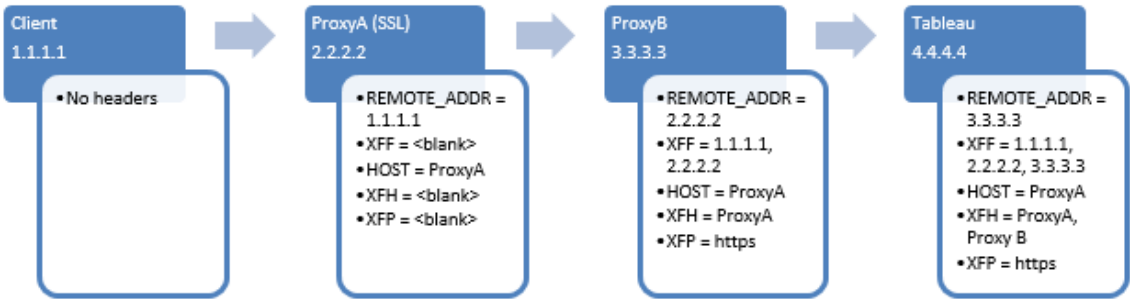

Configure the reverse proxy or load balancing server to work with Tableau Server

When a client accesses Tableau Server through a reverse proxy or load balancer, specific message headers have to be preserved (or added). Specifically, all servers in the message chain must be represented in the `gateway.trusted` and `gateway.trusted_hosts` settings.

The following graphic shows example headers for a single-hop message chain, where the proxy server is communicating directly with Tableau Server:

The following graphic shows example headers for a multiple-hop message chain, where the message traverses two proxy servers before connecting to Tableau Server:

The following table describes what these headers are and how they relate to the configuration settings on Tableau Server:

Headers	Description	Related Tableau Server settings
REMOTE_ADDR and X-FORWARDED-FOR (XFF)	Tableau Server needs these headers to determine the IP address of origin for requests. X-FORWARDED-FOR header must present IP address chain to Tableau Server in the order the connections have occurred.	The IP address that you set <code>ingateway.trusted</code> must match the IP presented in REMOTE_ADDR. if you sent multiple addresses <code>ingateway.trusted</code> , one of them must match the IP presented in REMOTE_ADDR.
HOST and X-FORWARDED-HOST (XFH)	These headers are used to generate absolute links to Tableau Server when it replies to the client. X-FORWARDED-HOST header must present host names to Tableau Server in the order the connections have occurred.	The host names that are presented in X-FORWARDED-HOST header must be included in the host names that you specify in <code>gateway.trusted_hosts</code> .
X-FORWARDED-PROTO (XFP)	This header is required if SSL is enabled for traffic from the client to	Port configuration on

	<p>the proxy, but not for traffic from the proxy to Tableau Server.</p> <p>The <code>X-FORWARDED-PROTO</code> headers are important for scenarios where HTTP or HTTPS is not maintained along each hop of the message route. For example, if the reverse proxy requires SSL for outside requests, but traffic between the reverse proxy and Tableau Server is not configured to use SSL, <code>X-FORWARDED-PROTO</code> headers are required. Some proxy solutions add the <code>X-FORWARDED-PROTO</code> headers automatically, while others do not. Finally, depending on your proxy solution, you might have to configure port forwarding to translate the request from port 443 to port 80.</p> <p>Related KB article: "Unable to Sign In" and "Invalid username or password" Error With SAML After Upgrading.</p>	<p>reverse proxy (inbound connections from client and outbound connections to Tableau Server) must be specified in the corresponding parameter: <code>gateway.public.port</code>, which is the port clients use to connect to the proxy.</p> <p>If the proxy server is using SSL to communicate with Tableau Server, SSL must be configured and enabled on Tableau Server.</p>

Deploy

The topics in this section provide information on installing, configuring, and upgrading Tableau Server on Windows.

Looking for Tableau Server on Linux? See [Install and Configure Tableau Server](#).

Validating your server deployment plan

Before you commit to installing a new Tableau Server deployment in your organization, be sure to carefully evaluate your options. For most organizations, Tableau Cloud will provide a more reliable, performant, and cost-effective analytics solution when compared to self-hosting Tableau Server. For information about the viability of Tableau Cloud for your organization, review this blog post, [Should I move my analytics to the cloud?](#)

Already running Tableau Server and want to migrate to Tableau Cloud? See [Tableau Cloud Manual Migration Guide](#).

If you have determined that you must self-host Tableau Server, we recommend following the prescribed Tableau deployment in the [Enterprise Deployment Guide](#) (EDG). The EDG presents a fully-tested and supported, performant, scalable, secure reference architecture based on a tiered data network. Moving forward, we are committed to investing in the EDG reference architecture to ease feature rollouts and improve upgrade scenarios.

Install and Configure Tableau Server

The topics referenced at the bottom of this page describe the steps to install and configure Tableau Server. If you are installing a distributed deployment (cluster), use the steps in this

topic to install the initial node, then, to install additional nodes, see [Distributed and High Availability Tableau Server Installations](#).

After you run the installation, you must then continue setup by activating a license, registering Tableau Server, and configuring various settings including authentication.

What version are you installing or upgrading to?

Beginning with Tableau Server on Windows version 2019.4.0, a new Setup program is used to install and upgrade Tableau Server. If you are installing or upgrading **to** version 2019.3.x or earlier, see the 2019.3 Server Help for instructions.

Other installation methods

There are a few alternative methods that you can use to install Tableau Server.

- If you want a quick start procedure to install Tableau Server in a non-production environment, see [Jump-start Installation](#).
- The topics included in this installation section describe how to install Tableau Server on Windows using the interactive installer. If you want to install Tableau Server using a command line, see [Automated Installation of Tableau Server](#).
- If you are installing Tableau Server in an environment without a connection to the internet, see [Install Tableau Server in a Disconnected \(Air-Gapped\) Environment](#).
- You can also install Tableau Server onto various cloud platforms. See [Self-Host Tableau Server in a Public Cloud Service](#).

Validating your server deployment plan

Before you commit to installing a new Tableau Server deployment in your organization, be sure to carefully evaluate your options. For most organizations, Tableau Cloud will provide a more reliable, performant, and cost-effective analytics solution when compared to self-host-

ing Tableau Server. For information about the viability of Tableau Cloud for your organization, review this blog post, [Should I move my analytics to the cloud?](#)

Already running Tableau Server and want to migrate to Tableau Cloud? See [Tableau Cloud Manual Migration Guide](#).

Moving forward, we are committed to investing in the EDG reference architecture to ease feature rollouts and improve upgrade scenarios.

Before you begin

To install Tableau Server you must have a computer that satisfies the hardware requirements. You will get an informational message if your computer meets the minimum requirements but does not satisfy the recommended minimum requirements. In this case, your computer hardware can handle a trial installation of Tableau but is not adequate for a production environment. For more information, see [Before you install](#)....

Installation steps

The following steps describe how to install Tableau Server on a single computer. Use the steps to install Tableau Server in a single server deployment. Use the steps to install the initial node in a multi-node Tableau Server deployment. Run the steps sequentially.

1. Install TSM
2. Activate and Register Tableau Server
3. Configure Initial Node Settings
4. Add an Administrator Account

Before you install...

Note: You can find additional information about technical specifications for Tableau Server on the Tableau web site, [here](#).

This topic includes requirements and recommendations that you must consider before you install Tableau Server into a production environment.

- If you are new to Tableau Server, and you want to deploy it in your organization, we encourage you to deploy Tableau Server as a single server in a test environment first. The easiest way to do a single-server installation is to follow the steps in Jump-start Installation.
- If you are deploying Tableau Server in a distributed cluster, review Distributed Requirements in addition to the requirements and recommendations described in this topic.

Validating your server deployment plan

Before you commit to installing a new Tableau Server deployment in your organization, be sure to carefully evaluate your options. For most organizations, Tableau Cloud will provide a more reliable, performant, and cost-effective analytics solution when compared to self-hosting Tableau Server. For information about the viability of Tableau Cloud for your organization, review this blog post, [Should I move my analytics to the cloud?](#)

Already running Tableau Server and want to migrate to Tableau Cloud? See [Tableau Cloud Manual Migration Guide](#).

If you have determined that you must self-host Tableau Server, we recommend following the prescribed Tableau deployment in the [Enterprise Deployment Guide](#) (EDG). The EDG presents a fully-tested and supported, performant, scalable, secure reference architecture based on a tiered data network. Moving forward, we are committed to investing in the EDG reference architecture to ease feature rollouts and improve upgrade scenarios.

Hardware recommendations for production installations

The following list describes the minimum hardware recommendations for a production use, single- node installation of Tableau Server:

Important: These recommendations are minimums and may not reflect the requirements for your installation and organization. For example, there are a number of factors that can impact disk space requirements, including whether or not you will be publishing extracts, flows, and the number of workbooks to Tableau Server. For more information on what might impact free disk space requirements, see [Disk Space Requirements](#).

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
Single node	<ul style="list-style-type: none">• 64-bit (x64 chipsets)• Must support SSE4.2 and POPCNT instruction sets• ARM-based processors are not supported	8 cores (16 vCPUs), 2.0 GHz or higher	<p>Version 2022.3 and later:</p> <ul style="list-style-type: none">• 128 GB <p>Version 2021.4.0 to version 2022.1.x:</p> <ul style="list-style-type: none">• 64 GB <p>Version 2021.3.x and earlier:</p> <ul style="list-style-type: none">• 32 GB	50 GB

If you are adding Tableau Prep Conductor to your Tableau Server installation, we recommend you add a second node and dedicate this to running Tableau Server Prep Conductor. This node should have a minimum of 4 cores (8 vCPUs), and 16 GB of RAM.

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
Multi-node and enterprise deployments	<p>Contact Tableau for technical guidance.</p> <p>Nodes must meet or exceed the minimum hardware recommendations, except:</p> <ul style="list-style-type: none"> • Dedicated Backgrounder nodes running up to two instances of backgrounder, where 4 cores may be acceptable. • Dedicated node for Tableau Prep Conductor: Minimum of 4 cores (8 vCPUs), and 16 GB of RAM. • Dedicated node for Independent Gateway: Minimum of 2 cores (4 vCPUs), 8 GB of RAM, and 100 GB free disk space. 			

Important: The disk space requirement cannot be checked until you initialize TSM.

- Free disk space is calculated after the Tableau Server Setup program is unzipped. The Setup program uses about 1 GB of space. You may need to allocate additional disk space depending on various factors like whether you will be using extracts.
- **Network attached storage space requirements for External File Store:** If you are planning to configure [Tableau Server with External File Store](#), you will need to estimate the amount of storage space to dedicate on your network attached storage.

Estimating the storage size: You must take into account the amount of storage needed for publishing and refreshing extracts. In addition, you must also take into account the repository backup size unless you specifically choose the option to do your repository backup separately as described in the Option 2: Back up repository separately topic.

- Extracts:
 - Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You

can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.

- Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.
- Repository Backup:
 - To obtain an estimate of the repository data, check the size of `<data directory>/pgsql/data/base directory`.
 - To obtain the exact size of the repository data, open the backup file and use the size of the `workgroup.pg_dump` file.
- Core count is based on "physical" cores. Physical cores can represent actual server hardware or cores on a virtual machine (VM). Hyper-threading is ignored for the purposes of counting cores.
- RAM shown is the minimum recommended for a single-node installation. Your installation may function better with more RAM, depending on activity, number of users, and background jobs, for example.

To see the full list of recommendations and to see the minimum requirements, see [Minimum Hardware Requirements and Recommendations for Tableau Server](#). For hardware specifications Tableau uses internally for testing scalability, see [Hardware recommendations for production installations](#).

For public cloud deployments on Amazon Web Services and Google Cloud Platform, their "vCPU" is actually a CPU hyper-thread, and not a full CPU core. When sizing cloud instances, you will need twice as many vCPU as the Tableau Server CPU core requirements given (8 vCPU required for a minimum trial installation, 16 vCPU recommended for a single-node installation).

Operating system requirements

The following 64-bit Microsoft Windows Server operating systems are supported

Note: Windows Server 2022 is *not* supported. Beginning in April 2023, installers for all versions of Tableau Server on Windows will block installation on Windows 2022.

- Tableau Server 2021.3.0 and later:
 - Windows Server 2016
 - Windows Server 2019

Earlier versions:

- Tableau Server 2020.1.0 - 2021.2.x:
 - Windows Server 2012
 - Windows Server 2012 R2
 - Windows Server 2016
 - Windows Server 2019
- Tableau Server 2019.1.0 - 2019.x:
 - Windows Server 2008 R2
 - Windows Server 2012
 - Windows Server 2012 R2
 - Windows Server 2016
 - Windows Server 2019

Note: All nodes in a multi-node cluster must have the same type of operating system. You cannot install a multi-node instance of Tableau Server on a combination of Linux and Windows nodes.

Installation directory

By default, Tableau Server will install on the system drive. The drive where Windows is installed is the system drive. In most cases, the system drive is the C:\ drive. In this default case, Tableau Server will install into the following directories:

- C:\Program Files\Tableau\Tableau Server\packages
- C:\ProgramData\Tableau\Tableau Server

Do not specify a symbolic link or a data directory location on a Network File System (NFS) volume.

Non-default installation locations

Rather than install onto the system drive, some organization install applications on a separate drive. During setup (or with automated installation), you can specify a different installation location. If you select a different installation drive or folder location during setup, then the data directory for Tableau Server will install into the same path. This means that if you install to a non-default location, the default C:\ProgramData\Tableau\Tableau Server path will not be created.

When you install to a non-default location, you must take the following into consideration:

- You may need to configure Run As service account permissions manually. If you do not use the predefined local account, NetworkServices, as the Run As service account, then you will need to set permissions for the account that you will be using. You must set these permissions after you install Tableau Server. See [Verify Folder Permissions](#).

- Log files are stored at <installation path or drive>\data\tabsvc\logs. The C:\ProgramData\Tableau\Tableau Server\data\tabsvc\logs path in a default installation is converted to <installation path or drive>\data\tabsvc\logs.
- You may need to specify the same location when you upgrade to newer versions of Tableau Server. For more information on upgrading, see Upgrade Tableau Server Overview.

Note: If you run Tableau Server on a VM, either locally, or in the cloud, be aware of the potential for complications related to licensing. This applies whether you are running Tableau Server as a standalone or in a cluster. If you are simply upgrading Tableau Server on the VM, you do not need to take any extra action related to licensing. If you plan to clone the VM to create either a new production or test environment to upgrade, you need to deactivate any Tableau Server licenses before cloning. If you do not do this, the new VM environment can end up with an untrusted license, and any attempts to upgrade will fail.

To clone a VM, make sure the Tableau Server is unlicensed (all licenses are deactivated). After cloning the VM, activate the Tableau license on the cloned VM and proceed with the upgrade.

- When installing a multi-node instance of Tableau Server, the installation location (path) must be the same on every node.

Tableau Prep Conductor

Tableau Prep Conductor is one of the process on Tableau Server. It runs a flow, checks connection credentials, and sends alerts if a flow fails. Tableau Prep Conductor leverages the scheduling and tracking functionality of Tableau Server so you can automate running flows to update the flow output instead of logging into Tableau Prep Builder to manually run individual flows as your data changes.

Tableau Prep Conductor is licensed separately and is available through the Data Management license. For more information on Tableau Prep Conductor licensing, see License Data Management.

We recommend you enable Tableau Prep Conductor on a dedicated node. For more information:

- If you are installing a new Tableau Server, see Step 1 (New Install): Install Tableau Server with Tableau Prep Conductor.
- If you are adding Tableau Prep Conductor to an existing installation of Tableau Server, see Step 1 (Existing Install): Enable Tableau Prep Conductor.

Additional requirements

Make sure that your environment also meets the following additional requirements:

Hostname

- Tableau Server must be able to resolve the hostname to an IP address either using the domain name server (DNS) or with a local host file on the computer running Tableau Server. By default, host files are stored at `\Windows\System32\Drivers\etc\hosts`.
- The hostname of the server must not change after you start Tableau Services Manager during the setup process. For example, this might happen if you use the cloud-init package to initialize a virtual machine, and you install Tableau Server on that virtual machine.
- Hostnames that include underscores (`_`) are not supported by Tableau Server.

Static IP address

The computer where you install Tableau Server must have a static IPv4 or IPv6 address.

If both IPv4 and IPv6 are enabled or multiple network cards (NICs) are being used, unexpected behavior can result. For more information, see the following:

- **For Tableau Server deployments running on Windows Server 2019:** Changes to Windows Server 2019 IPv6 configuration behavior can result in IPv6 taking precedence

over IPv4. To verify IPv6 precedence, review the [Tableau Server IPs changed and not all TSM services are coming up correctly](#) article in the Tableau Knowledge Base and update your computer settings.

- **When multiple NICs are being used:** In deployments where multiple NICs are used, review Troubleshoot Inconsistent Process Status for best practices.

Database drivers

To connect to specific data sources, the computer where you install Tableau Server must have the correct database drivers installed. For more information, see Database Drivers.

Available ports

TSM and Tableau Server each require an available TCP port in order for you to access them. TSM defaults to port 8850, and the Tableau Server Gateway service defaults to port 80. We strongly recommend that you ensure that both port 8850 and 80 are not in use on your system before installing Tableau Server. If those ports are not available, the TSM and gateway ports may be dynamically remapped to different port numbers, and there is currently no interface for displaying which port they have been remapped to.

If you are installing Tableau Server on a computer that's also running IIS (not a recommended deployment), you should modify the Tableau's gateway port number to avoid conflict with IIS. You can specify a different gateway port number during the setup process.

See Tableau Services Manager Ports.

Local firewall configuration

If you are running a firewall on the computer where you will be installing Tableau Server, then you will need to open the following default ports for Tableau Server traffic. All port numbers, except 443 can be changed.

Port	TCP/UDP	Used by ...	TYPE OF INSTALLATION	
			All	Distributed / High Availability
80	TCP	Gateway	X	
443	TCP	SSL. When Tableau Server is configured for SSL, the application server redirects requests to this port. Do not change this port.	X	
8850	TCP	Tableau Services Manager.	X	
8060	TCP	PostgreSQL database.	X	
8061	TCP	PostgreSQL backup verification port	X	
8000-9000	TCP	Range of ports reserved by default for dynamic mapping of Tableau processes		X
27000-27009	TCP	Range of ports used by Tableau Server for License service. This range must be open on the node running the License service and accessible from other nodes. By default, the initial node runs the License service.	X	

See Tableau Services Manager Ports

For information about configuring the local Windows firewall, refer to the Microsoft product documentation.

Local administrator

The account that you use to run Setup must be a member of the Local Administrators group on the Windows computer where Tableau Server is installed.

By default, you must also use an account with local administrator rights to run Tableau Services Manager (TSM) Web UI and CLI tools. However, after you have installed Tableau Server, you can specify a Windows group for TSM administration. See [Configure a Custom TSM Administration Group](#).

Use TSM to configure the Tableau Server components that rely on OS-level access, such as processes, authentication, log files, licensing, and alerts. See [TSM Authentication](#).

Tableau-specific administration, such as importing users, creating sites, web authoring, etc. is performed by Tableau Server administrators. You can configure these administrative accounts by assigning roles to users after you install. The initial Tableau Server administrator account is created as part of the installation process. See [Add an Administrator Account](#).

Run As service account

A Run As service account for the Tableau Server service to run under is useful if you're using NT Authentication with data sources or if you're planning on doing SQL Server impersonation. For more information, see [Run As Service Account and SQL Server Impersonation](#).

In some organizations, Group Policy or other system management solutions are used to standardize permissions and accounts on application servers. If your organization runs a such a solution, be sure to configure the system to accommodate the folder permissions required by the Run As service account. See [Verify Folder Permissions](#).

Antivirus software

Antivirus software that scans directories used by Tableau Server can interfere with installation and ongoing use of Tableau Server. In some cases, this can result in installation failures, problems starting Tableau Server, or impacts to performance. If you plan to run antivirus software on the computer running Tableau Server, follow the recommendations in the [Knowledge Base](#).

Continue to the next step: [Install and Configure Tableau Server](#).

Minimum Hardware Requirements and Recommendations for Tableau Server

The following minimum hardware requirements and recommendations apply to all computers running Tableau Server, including physical hardware and virtual machines (VMs):

- **Minimum requirements for installation** reflect the minimum hardware your computer must have in order to install Tableau Server. We do not recommend you attempt run Tableau Server on servers with these values, even if you are just testing. Depending the features you have licensed and are using, you may experience poor performance and an unrealistic experience. In certain cases Tableau Server may not start without at least 20GB of memory.

For prototyping and Proof of Concept (PoC) testing, we recommend you use Tableau Cloud. This will give you an opportunity to experience Tableau Server on appropriately sized hardware.

- **Minimum recommendations for production** go beyond minimum installation requirements, and represent the minimum hardware configuration you should use for installation on most production nodes. If your computer meets the minimum installation requirements but does not meet these recommendations, the Setup program will warn you but you can continue the installation. For certain nodes dedicated to specific tasks and processes such as backgrounder, or Prep, you may be able to use servers that do not meet this minimum recommendation.

The minimum recommendations listed here are intended as general guidance. However the recommendations for your environment may vary. For more information, see the [Hardware recommendations section](#) of the [Recommended Baseline Configurations](#) topic.

In addition, Tableau Server should not be installed on a physical computer or on a VM instance that is also running resource-intensive applications such as databases or application servers.

Note: If you install Tableau Server on a computer that meets the minimum requirements but does not have at least 8 cores and 16 GB of system memory, the default number of all processes installed is reduced to one of each process by design. For more information about processes, see [Server Process Limits](#)

Looking for Tableau Server on Linux? See [Minimum Hardware Requirements and Recommendations for Tableau Server](#).

Minimum installation hardware requirements

We strongly recommend any Proof of Concept (PoC) testing or prototyping be done using Tableau Cloud. This guarantees you will be running on systems with adequate resources.

The computer on which you are installing or upgrading Tableau Server must meet the minimum hardware installation requirements. If the Setup program determines that your computer does not meet the following requirements, you will not be able to install Tableau Server. Meeting these requirements does not guarantee you a good experience testing Tableau Server

For more information on how the Setup program determines hardware, see [Determining Computer Hardware](#).

Minimum Hardware Requirements

These minimum requirements are for installing Tableau Server. They do not guarantee successful testing or use. For production minimum recommendations, see [Minimum production hardware recommendations](#).

<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
<ul style="list-style-type: none">64-bit (x64 chipsets)	4 cores (8	Version 2022.3 and	15 GB

<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
-------------------------	-------------------	-------------------	-------------------------------

- | | | | |
|---|--------|---|--|
| <ul style="list-style-type: none"> • Must support SSE4.2 and POPCNT instruction sets • ARM-based processors are not supported | vCPUs) | later: <ul style="list-style-type: none"> • 64 GB - initial node • 16 GB - additional nodes | |
|---|--------|---|--|

Version 2022.1 and earlier:

- 16 GB - all nodes

- Free disk space is calculated after the Tableau Server Setup program is unzipped. The Setup program uses about 1 GB of space. You may need to allocate additional disk space depending on various factors like whether you will be using extracts.
- Core count is based on "physical" cores. Physical cores can represent actual server hardware or cores on a virtual machine (VM). Hyper-threading is ignored for the purposes of counting cores.

Minimum production hardware recommendations

For production use, the computers on which you install or upgrade Tableau Server should, in most cases, meet or exceed the minimum hardware recommendations. These recommendations are general. Actual system needs for Tableau Server installations can vary based on many factors, including number of users and the number and size of extracts, as well as the features you have licensed. If the Setup program determines that your computer does not meet the following recommendations, you will get a warning, but you can continue with the installation process. For more information, see the Hardware recommendations for production installations.

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
Single node	<ul style="list-style-type: none"> • 64-bit (x64 chipsets) • Must support SSE4.2 and POPCNT instruction sets • ARM-based processors are not supported 	8 cores (16 vCPUs), 2.0 GHz or higher	Version 2022.3 and later: <ul style="list-style-type: none"> • 128 GB Version 2021.4.0 to version 2022.1.x: <ul style="list-style-type: none"> • 64 GB Version 2021.3.x and earlier: <ul style="list-style-type: none"> • 32 GB 	50 GB

If you are adding Tableau Prep Conductor to your Tableau Server installation, we recommend you add a second node and dedicate this to running Tableau Server Prep Conductor. This node should have a minimum of 4 cores (8 vCPUs), and 16 GB of RAM.

Multi-node and enterprise deployments	<p>Contact Tableau for technical guidance.</p> <p>Nodes must meet or exceed the minimum hardware recommendations, except:</p> <ul style="list-style-type: none"> • Dedicated Backgrounder nodes running up to two instances of backgrounder, where 4 cores may be acceptable. • Dedicated node for Tableau Prep Conductor: Minimum of 4 cores (8 vCPUs), and 16 GB of RAM. • Dedicated node for Independent Gateway: Minimum of 2 cores (4
---------------------------------------	---

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
---------------------	------------------	------------	------------	------------------------

vCPUs), 8 GB of RAM, and 100 GB free disk space.

Important: The disk space requirement cannot be checked until you initialize TSM.

- Free disk space is calculated after the Tableau Server Setup program is unzipped. The Setup program uses about 1 GB of space. You may need to allocate additional disk space depending on various factors like whether you will be using extracts.
- **Network attached storage space requirements for External File Store:** If you are planning to configure [Tableau Server with External File Store](#), you will need to estimate the amount of storage space to dedicate on your network attached storage.

Estimating the storage size: You must take into account the amount of storage needed for publishing and refreshing extracts. In addition, you must also take into account the repository backup size unless you specifically choose the option to do your repository backup separately as described in the [Option 2: Back up repository separately](#) topic.

- Extracts:
 - Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.
 - Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.
- Repository Backup:
 - To obtain an estimate of the repository data, check the size of `<data directory>/pgsql/data/base` directory.

- To obtain the exact size of the repository data, open the backup file and use the size of the `workgroup.pg_dump` file.
- Core count is based on "physical" cores. Physical cores can represent actual server hardware or cores on a virtual machine (VM). Hyper-threading is ignored for the purposes of counting cores.
- RAM shown is the minimum recommended for a single-node installation. Your installation may function better with more RAM, depending on activity, number of users, and background jobs, for example.

To see the full list of recommendations and to see the minimum requirements, see [Minimum Hardware Requirements and Recommendations for Tableau Server](#). For hardware specifications Tableau uses internally for testing scalability, see [Hardware recommendations for production installations](#).

For hardware recommendations for Tableau Server in the cloud, see the following:

- Selecting an AWS Instance Type and Size in the [Tableau Server on Windows in the AWS Cloud Administrator Guide](#)
- Selecting a Google Compute Engine Virtual Machine Type and Size in the [Tableau Server on Windows in the Google Cloud Platform Administrator Guide](#)
- Selecting a Microsoft Azure Virtual Machine Type and Size in the [Tableau Server on Windows in Microsoft Azure Administrator Guide](#)

Determining Computer Hardware

To determine how many physical cores a computer has, the Tableau Server setup program queries the operating system. To view hardware information that the setup program detected on your computer, open the `app-install.log` file in the following folder on the computer where you are installing Tableau Server:

```
<install directory>\ProgramData\Tableau\Tableau Server\logs\app-  
install.log
```

Tableau Server on Windows Help

In the `app-install.log` file, look for lines similar to the following. These lines provide information about the physical cores that the setup program detected and that it used to determine the core count that is being used for licensing, as well as the amount of system memory that was detected.

```
2020-11-24 17:40:43.842 +0000 main : DEBUG com.tableau-ware.tabadmin.configuration.builder.BootstrapConfigurationBuilder - System processor count = 8

2020-11-24 17:40:43.842 +0000 main : DEBUG com.tableau-ware.tabadmin.configuration.builder.BootstrapConfigurationBuilder - System memory = 64383MB
```

Manually determining the number of cores on your computer

To determine manually how many physical cores your server has, you can use the Windows Management Instrumentation Command-line tool (WMIC). This is useful if you do not know whether your computer will meet the minimum hardware requirements for installing Tableau Server.

1. Open a command prompt.
2. Enter the following command:

```
WMIC CPU Get DeviceID,NumberOfCores
```

The output will display the device ID or IDs and the number of physical cores the computer has.

```

Administrator: Command Prompt
C:\>WMIC CPU Get DeviceID,NumberOfCores
DeviceID  NumberOfCores
CPU0      6
CPU1      6
C:\>_

```

In this example, there are two CPUs, each with six cores, for a total of twelve physical cores. This computer would satisfy the minimum hardware requirements for installing Tableau Server.

The following command shows a longer version that lists the logical processors as well as the physical cores.

```
WMIC CPU Get DeviceID,NumberOfCores,NumberOfLogicalProcessors,SocketDesignation
```

```

Administrator: Command Prompt
C:\>WMIC CPU Get DeviceID,NumberOfCores,NumberOfLogicalProcessors,SocketDesignation
DeviceID  NumberOfCores  NumberOfLogicalProcessors  SocketDesignation
CPU0      6              12                        CPU 1
CPU1      6              12                        CPU 2
C:\>_

```

In the above example, the server has a total of twelve physical cores, resulting in 24 logical cores.

Install TSM

This topic guides you through the process of installing Tableau Server Tableau Services Manager (TSM).

Important: Do not install a beta version of Tableau Server in your production environment. You should also never restore a production Tableau Server installation using a backup of a beta version.

Prerequisites

Before proceeding, review the topic, [Before you install....](#)

Use the TSM web interface

Running Setup

After you download the Tableau Server installation file, follow the instructions below to install the server.

Important: Do not install a beta version of Tableau Server in your production environment. You should also never restore a production Tableau Server installation using a backup of a beta version.

1. Sign in as a user with administrator access to the computer where you want to install Tableau Server and double-click the installation file.
2. Follow the on-screen instructions to complete Setup and install the application.

The default installation path is `C:\Program Files\Tableau\Tableau Server-<version>`. The Setup program displays the install path without the version, like this: `C:\Program Files\Tableau\Tableau Server`. You can choose a different location, including a different drive, either by browsing to or typing in a new path. Be aware that if you browse to a location, the Setup program appends `\Tableau Server` to the end of the path. You can remove this if it is not the location you want.

If you are upgrading from Tableau Server version 2018.1 or earlier and Tableau was installed to a non-default location, you need to specify the location of your existing version. Upgrade steps vary depending on your target version and install location. See [Upgrade Tableau Server Overview](#) for information on how to choose your upgrade steps.

Note: If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

3. Click **Next**.

On the **Server installation type** page, you can specify whether you are installing the first node of a Server installation, or additional nodes in a multi-node installation. You do not need to change this from the default (Create new Tableau Server installation.) unless you are installing a multi-node Tableau Server. If you are installing a multi-node Tableau Server, see [Install and Configure Additional Nodes](#).

4. Click **Next**.

On the **Product activation type** page, select whether you want to use the Tableau authorization-to-run (ATR) service to activate Tableau Server (the default), and then click **Install**. For more information about the Tableau authorization-to-run (ATR) service, see [Activate Tableau Server using the authorization-to-run \(ATR\) service](#).

5. After the installation completes, click **Finish**. Setup will then open the TSM configuration web page on the computer where you are installing Tableau Server.

If you need to support characters that are not the Latin-1 set, install the Windows Language Packs via **Control Panel > Regional and Language Options**. The language packs will need to be installed on the initial server as well as any additional nodes.

Use the TSM CLI

Install Tableau Server

1. Open a command prompt as a user with administrator access to the computer where you want to install Tableau Server.
2. Download the Setup program from the [Tableau Server Downloads](#) page.
3. Navigate to the directory where you copied the Setup program.
4. Run the Setup program from the command line using the `/silent` flag (run unattended and silently with no UI prompts), `ACCEPTTEULA` (accept the End User License Agreement), and `ACTIVATIONSERVICE` (use Server ATR to activate Tableau Server) properties:

```
TableauServer-64bit-<version>.exe /silent ACCEPTTEULA=1  
ACTIVATIONSERVICE="1"
```

Note: There are a number of different installation options you can specify during CLI installation, for example, to change installation and logging paths, or to specify the TSM controller port. For a complete list of switches that you can specify during CLI installation, see [Install Switches and Properties for Tableau Server](#).

5. Close the command window and open a new one, then confirm that TSM is installed and running:

```
tsm status -v
```

The status will be `STOPPED` but the tsm-specific processes will be running:

```
node1: localhost
Status: STOPPED
'Tableau Server Coordination Service 0' is running.
'Tableau Server Administration Agent 0' is running.
'Tableau Server Administration Controller 0' is running.
'Tableau Server License Manager 0' is running.
'Tableau Server Client File Service 0' is running.
```

Configure Tableau Server for a forward proxy

If your organization uses a forward proxy solution to access the internet, then configure Tableau Server to use the proxy server. Tableau Server must access the internet for map data and for default licensing functionality.

We recommend configuring Tableau Server for a forward proxy solution at this point of the installation process. See [Configuring Tableau Server on Windows to work with a forward proxy](#).

Next step

- [Activate and Register Tableau Server](#)

Activate and Register Tableau Server

Before you can use Tableau Server, you must activate and register it.

Tableau Server requires at least one product key that both activates the server and specifies the number of license levels you can assign to users. You can access your product keys from the [Customer Portal](#).

If you need to activate Tableau Server on a computer that is offline, see [Activate Tableau Server Offline](#). If you need to activate additional product keys to add capacity to an existing Tableau Server installation, see [Add Capacity to Tableau Server](#).

Prerequisite

Before proceeding with the procedures in this topic, complete the following prerequisites as outlined in [Install and Configure Tableau Server](#):

- Install TSM
- TSM uses port 8850. If you are running a local firewall, open port 8850.
- [Configure Product Key Operations with Forward Proxy](#)

Use the TSM web interface

1. If the computer where you are installing Tableau Server has been configured to connect to the internet through a forward proxy, follow the procedure in the topic, [Configure Product Key Operations with Forward Proxy](#), before continuing.

2. Sign in to Tableau Services Manager Web UI.

The account you use must have administrative privileges on the computer where TSM is installed.

3. On the **Activate** page, Enter or paste your product key and click **Activate Product Key**.

Note: In versions prior to 2023.3.0 an option to activate a trial license displays. This option was removed as of version 2023.3.0. To learn about options for trying Tableau Server, contact your account representative.

After your product key is activated, it appears under **Activated Product Keys**.

Activate Register Setup Initialize

Enter your license product key to get started with Tableau Server.

Product Key

The key has 20 characters

0000-0000-0000-0000-000

[I can't find my product key.](#)

Enter your product key and click Activate Product Key. If activating multiple keys, do this for every key. When you have added all keys, click Next. You can access your product keys from the [Tableau Customer Portal](#).

Activated Product Keys
No product key currently activated

Activate Product Key Next

4. To activate another product key, type over the key you just entered to add the new product key, and then click **Activate Product Key**. After your product key is activated, it appears under **Activated Product Keys**. Continue adding product keys in this manner until you're done.
5. When you're finished activating product keys, click **Next**.

Note: If the product keys you have activated don't have the necessary capacity, such as not enough cores or only a Viewer role product key, Tableau Services Manager displays the **Insufficient licenses applied** dialog box. Click **Activate Another Product Key** to add another product key and increase capacity on your Tableau Server installation.

Tableau Server on Windows Help

Insufficient licenses applied

You have not activated enough product keys for your Tableau Server deployment.

If you try to activate Tableau Server using these licenses, it may not run properly. We recommend that you activate additional licenses to support this Tableau Server deployment

[Tableau Customer Portal](#)
[Troubleshooting](#)

[Activate Another Product Key](#)

6. On the **Register** page, enter your information into the fields and click **Register**.

Register with Tableau. All fields are required.

Contact Information

First Name	Last Name
<input type="text"/>	<input type="text"/>
Phone Number	Email
<input type="text"/>	<input type="text"/>

Company Information

Organization	
<input type="text"/>	
Industry	Company Size
<input type="text"/>	<input type="text"/>
Department	Job Role
<input type="text"/>	<input type="text"/>

Region Information

City	Postal Code
<input type="text"/>	<input type="text"/>
Country/Region	State/Province
<input type="text"/>	<input type="text"/>

Use the TSM CLI

Configure for forward proxy

If the computer where you are installing Tableau Server has been configured to connect to the internet through a forward proxy, follow the procedure in the topic, [Configure Product Key Operations with Forward Proxy](#), before continuing.

Activate Tableau Server

To activate Tableau Server for production use, you must have a product key.

To activate a product key, run the following command:

```
tsm licenses activate -k <product key>
```

To activate a two-week trial, run the following command:

```
tsm licenses activate -t
```

If you are unable to activate Tableau, for example, if you get an error like this:

```
License Server not available
```

see [Activate Tableau Server Offline](#).

What if I get an access denied error when I attempt to run TSM commands?

Verify that the account you are using is a member of the Local Administrators group on the Windows computer where you are installing Tableau Server.

Register Tableau Server

After activation, you need to register Tableau Server. To do this, create a registration file and then pass it as an option with the `tsm register` command.

1. Generate a template that you can edit by running the following command:

```
tsm register --template > /path/to/<registration_file>.json
```

2. Edit the template file to create your completed registration file.

Here is an example of a registration file in the required format:

```
{
  "first_name" : "Andrew",
  "last_name" : "Smith",
  "phone" : "311-555-2368",
  "email" : "andrew.smith@mycompany.com",
  "company" : "My Company",
  "industry" : "Finance",
  "company_employees" : "500",
  "department" : "Engineering",
  "title" : "Senior Manager",
  "city" : "Kirkland",
  "state" : "WA",
  "zip" : "98034",
  "country" : "United States",
  "opt_in" : "true",
  "eula" : "true"
}
```

3. After saving changes to the file, pass it with the `--file` option to register Tableau Server:

```
tsm register --file /path/to/<registration_file>.json
```

For example:

```
tsm register --file C:\Users\mwatson\Documents\tableau-reg-
file.json
```

If you have a product key for Data Management or Advanced Management, you must activate that key to use the additional functionality. Product keys for these licenses should only be activated after at least one capacity product key has been activated on the server.

- For license information on Tableau Data Management, see License Data Management.

- For license information on Tableau Advanced Management, see [About Tableau Advanced Management on Tableau Server](#).

Next step

- [Configure Initial Node Settings](#)

Activate Tableau Server Using the Authorization-To-Run (ATR) Service

You can use the Server authorization-to-run (ATR) service to activate Tableau Server deployed in on-premises, cloud, container, or virtual environments without running out of license activations. The ATR service achieves this by providing short-term leases of configurable duration (ATR duration) which ties the license to the device until product key expiration date is met. ATR handles activation capacity tracking so if there is an underlying hardware change, maximum activation errors don't occur. This option is recommended for all Tableau Server installations.

If you are activating Tableau Server online (this is the default), Tableau Server connects to various internet locations for licensing purposes. For more information, see [Communicating with the Internet](#).

If you are activating Tableau Server offline, you can still use ATR service to activate, however there are slight differences in how ATR duration works with offline activations. For more information, see [Activate Tableau Server Offline](#).

We recommend using the Server authorization-to-run (ATR) service to simplify server licensing. If you chose not to use Server ATR, you will use the legacy licensing technology which does not provide the dynamic management capabilities of Server ATR.

Your choice of activation type will be permanent for this installation of Tableau Server. To change this later, you must backup, remove, and then reinstall Tableau Server.

How Tableau Server ATR works

When ATR service is enabled, Tableau Server periodically contacts a Tableau-hosted authorization-to-run (ATR) service to verify that Tableau is authorized to run, based on its license and

the length of the authorization window (ATR duration or lease). As long as this communication is successful, Tableau runs without any impact to the user.

ATR Duration

By default, an instance of Tableau Server is given a 5 day ATR lease (duration) to successfully contact the ATR service for verification. This means that after the initial authorization, Tableau Server could be used for 5 days without network connection before the activation expired. The authorization checks between Tableau Server and ATR service are attempted regularly, and each time a check is successful, the ATR duration is reset to its full length. The authorization check frequency varies, and is dependent on the ATR duration:

ATR duration	Authorization check frequency
< 4 hours	every 15 minutes
< 24 hours	every 1 hour
< 7 days	every 12 hours
> 7 days	every 24 hours

For example: If the ATR duration is 48 hours, Tableau Server will contact the ATR service every 12 hours to complete an authorization check and the ATR duration is reset to 48 hours after each successful authorization check. The ATR duration will then begin to count down to 0 until the next authorization check. If the Tableau Server machine is shut down or there is no internet access, Tableau Server can no longer contact ATR service. If this happens, the ATR duration will not be reset to 48 hours and will continue to count down to 0. If Tableau Server is not started or cannot communicate with the ATR service before the ATR duration reaches 0, the license will expire and you must activate the license again.

Note: You should keep your Tableau Server running as much as possible. If Tableau Server cannot successfully complete an authorization check within the ATR duration

period, ATR service will reclaim the license lease and then you'll need to reactivate your license.

Set or change the Server ATR duration

When using Server authorization-to-run (ATR) to activate Tableau Server, you can change the ATR duration and use a setting different than the default of 432000 seconds (5 days). If you're creating a test server or virtual machine (VM) that will have a short lifespan, you might want to shorten the ATR duration. Similarly, if you have a server that you plan to keep for a long time, you might want to lengthen the ATR duration.

To change the ATR duration, you use the `tsm licenses atr-configuration set --duration <value_in_seconds>` command. For more information, see [tsm licenses atr-configuration set](#).

To view the ATR duration, see [tsm licenses atr-configuration get](#).

ATR duration in seconds	Minimum	Maximum	Default
Tableau Server (non-container)	3600 (1 hour)	7776000 (90 days)	432000 (5 days)

To set ATR duration and manually start the Activation Service, run the following commands:

Note: You must run these commands as an administrator from a command prompt. Depending on how your computer is configured, you may need to run them in the C:\Windows\System32 folder.

1. On the initial node, open a command prompt as administrator, and then use the following commands.
2. `tsm licenses atr-configuration set --duration <value_in_seconds>`

3. `tsm pending-changes apply`
4. `net stop activationsservice_0`
5. `net start activationsservice_0`

Move a Server ATR product key to another Tableau Server

If you want to stop using your product key on an existing Tableau Server and use it on a new installation of Tableau Server, you can move your Server ATR product key. You might want to move product keys when:

- Switching between development or pre-production environments.
- Moving Tableau Server to upgraded hardware.
- Moving Tableau Server to cloud infrastructure.
- Using an ephemeral Tableau Server, such as a virtual machine (VM) or container.

Deactivate a product key for reuse on another Tableau Server

Deactivate a product key in version 2021.4 and later

You can remove product key(s) that were activated using Server ATR when you want to reclaim license capacity from one Tableau Server installation and use it on another. For more information about reclaiming a product key, see [Deactivate Product Key](#).

Deactivate a product key in version 2021.3 and earlier

When ATR service is used to activate a Tableau Server license you cannot manually deactivate the license. You can have one production and two non-production installations per license. If you have unused activations on a license, you can activate the same license on another Tableau Server. If you're out of activations, you can still activate the license after the ATR lease expires by taking the following steps:

1. Disable the existing Tableau Server from refreshing its leased activation. You can do this using any of the following methods:

- Shut down your existing Tableau Server.
 - Uninstall the existing Tableau Server.
 - Disconnect the existing Tableau Server from the Internet by unplugging the ethernet cable or disconnecting wifi.
2. After the ATR lease expires, you can reuse the license on another Tableau Server.
 3. On the new computer, install Tableau Server.

When prompted, activate Tableau Server using the same license.

Activate Tableau Server Offline

When you install Tableau Server, you have to activate at least one product key, but we recommend that you activate all Tableau Server licenses found in the Tableau Customer Portal. Doing this activates the server, and specifies the number of license levels you can assign to users. For offline activations, you should activate the product key listed in the **Offline Activation Id** field in the Tableau Customer Portal.

There are also times you may need to activate licenses after Tableau Server is installed, for example, if you add capacity to your server, or get a new product key. If you don't have your product key, you can get it from the [Tableau Customer Account Center](#).

Note: Activating any product key after Tableau Server has already started will require a Tableau Server restart for the changes to take effect.

In most cases, you can activate your key directly from Tableau Server, either during installation, or later, using the Tableau Services Manager (TSM) Licenses page, but there are some circumstances that don't allow you to do this. If your computer is not connected to the internet for example, or has a firewall that restricts access outside your intranet. In these cases you need to do an offline activation.

Offline activation and login-based license management (LBLM)

Beginning in Tableau Server version 2023.1.0, offline activation is supported for LBLM when your server is configured to use the Authorization-to-Run (ATR) service. You can only configure Tableau Server to use the ATR service during a new install. Upgrading customers with existing server installations need to install a new instance of Tableau Server version 2023.1.0 or later and restore a backup of their existing installation to that new instance. For information on this process, see [Using a Blue/Green approach for upgrading Tableau Server](#).

There are two scenarios in which you may need to do an offline activation:

- Offline activation during install—To complete an offline activation when you are installing Tableau Server.
- Offline activation of licenses after install—To complete an offline activation after your server is installed and running.

Offline activation overview

Offline activation of Tableau Server involves the following steps:

1. Generate an offline activation request file.
2. Copy the offline activation request file to a computer with internet access.
3. Upload the offline activation request file to the [Tableau activation website](#).
4. Download the resulting offline activation response file from the website. You'll use this file to activate Tableau Server

Offline activation file name changes

Beginning in Tableau Server version 2023.1, the Tableau licensing system supports two underlying licensing technologies. From an administrative perspective, the only configuration difference between the two systems is the file types that are generated and consumed for offline activation. The licensing technology is determined during the initial installation of Tableau Server, and cannot be changed after install.

We refer to the legacy (and still supported) version of licensing technology as FlexNet. The latest version of the technology is referred to as Server ATR. For more information, see [Activate Tableau Server Using the Authorization-To-Run \(ATR\) Service](#). The following table describes the file naming nomenclature for each technology. The table also includes the generic reference.

Generic file name	Server ATR file names	FlexNet file names
Off-lineActivationRequest	Off-lineActivationRequestFile_YYYYMMdd.hhmmss.json	Tableau-OfflineActivationRequest.tlq
Off-lineActivationResponse	Off-lineActivationLicensingAtrs.zip	activation.tlf

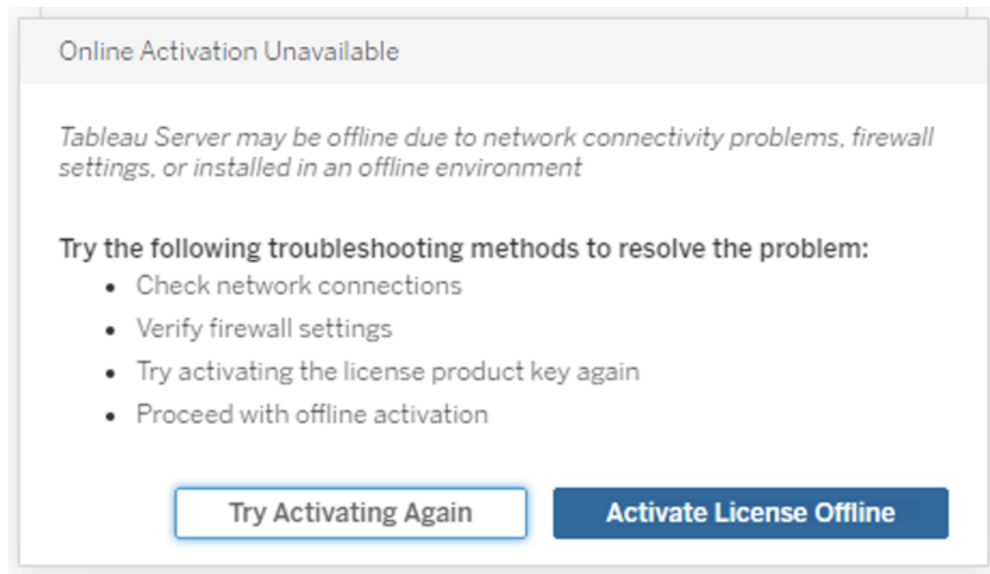

Note: Since this documentation supports multiple versions of Tableau Server, we will use the generic file name references (OfflineActivationRequest and Off-lineActivationResponse) for the rest of this topic. You can identify the licensing technology your Tableau Server installation uses according to the file type that generated in the steps that follow.

Use the TSM web interface

If you attempt to activate your product key from the TSM licenses page and see a dialog that says online activation is unavailable, you can activate the key offline. The offline activation

process must be completed once for each product key.

1. Click **Activate License Offline**.

2. Create an offline activation request file (OfflineActivationRequest) for the product key.

Create an OfflineActivationRequest file you will upload to the Tableau activation website. If your product key is not pre-filled in the form, enter your key and click **Create Offline File** to generate an OfflineActivationRequest file on the local computer.

Step 1: Create, Upload, and Submit an Offline File

Enter a product key then create, save, and move the Tableau Offline Activation Request file to a computer connected to the Internet. You will then need to upload and submit the offline file to Tableau (Step 2).

The key has 20 characters

Create Offline File

Access a computer connected to the Internet and go to <http://www.tableau.com/support/activation>. Upload and submit the Tableau Offline Activation Request file created above. This will generate the first Offline Activation file to upload in Step 2.

Copy the OfflineActivationRequest file to a computer with internet access. You need to upload this file to the Tableau activation website to generate an activation response file.

3. Upload and submit the OfflineActivationRequest file.

You will upload and submit the OfflineActivationRequest file to the Tableau activation website. This automatically generates an activation response file (OfflineActivationResponse) that you can download and copy back to the Tableau Server computer.

- a. On the computer where you copied the OfflineActivationRequest file, open a browser and go to <http://www.tableau.com/support/activation> to open the Tableau Support Activation page.
- b. On the Offline Activation page, click **Choose File** to select the OfflineActivationRequest file.
- c. Click **Upload Activation File** to submit the file to the Tableau activation website.
- d. Click the [here](#) link to download the OfflineActivationResponse file to your computer.

Offline Activation

The activation was successful. Please click [here](#) to download your activation file.

For help creating the offline activation file, see [Activate Tableau Desktop Offline](#) or [Activate Tableau Server Offline](#). ([Linux](#))

- e. Copy the OfflineActivationResponse file to the computer where Tableau Server is installed.
4. Upload the OfflineActivationResponse file.

On the Tableau Server computer, click **Upload Activation File** to upload the OfflineActivationResponse file to Tableau Server. When you do this successfully, the **Activate Product Key** button is enabled.

Step 2: Upload Activation File

Upload the Offline Activation file you downloaded from <http://www.tableau.com/support/activation> to activate your server and desktop client offline.

[Upload Activation File](#)

After activating product key, you can go back to Step 1 to enter another product key.

[Cancel Offline Activation](#) [Activate Product Key](#) [Next](#)

5. Click **Activate Product Key** to complete the offline activation.
6. (Skip this step if you are installing Tableau Server for the first time.)

Restart Tableau Server for licensing changes to take effect.

Use the TSM CLI

Step 1. Log in to Tableau Services Manager

Before you can proceed you must log in to Tableau Services Manager (TSM). To log in to TSM, run the following command:

```
tsm login -u <username>
```

What if I can't log in?

Verify that the account you are using is a member of the Local Administrators group on the Windows computer where you are installing Tableau Server.

Step 2. Generate an offline activation request file

1. On the initial node, open a command prompt as administrator.
2. Type this command to get your offline activation file:

Tableau Server on Windows Help

```
tsm licenses get-offline-activation-file -k <product-key> -o  
<target-directory>
```

You can get your product key from the [Tableau Customer Portal](#). The target directory must already exist.

3. Copy the offline activation file (OfflineActivationRequest) from the target directory to a computer that has internet access.

Step 3. Upload the offline activation request to the Tableau activation website

1. On the computer that has internet access, go to the Tableau [Product Activations](#) page.
2. Complete the instructions to upload your OfflineActivationRequest file.

This creates an activation response file (OfflineActivationResponse).

3. Download the OfflineActivationResponse file from the Tableau activation website.

Step 4. Initialize or activate your license

1. Copy the OfflineActivationResponse file to a location accessible from the Tableau Server computer.
2. Run the following command:

```
tsm licenses activate -f <path-and-activation-file>
```

3. (Skip this step if you are installing Tableau Server for the first time.)

Restart Tableau Server for licensing changes to take effect:

```
tsm restart
```

4. (Optional) To verify that all licenses are activated, you can run this command:

```
tsm licenses list
```

If you have completed the steps above, you should see a success message:

```
Activation successful.
```

Tableau Server is activated. If you need additional assistance, contact [Tableau Technical Support](#).

Configure Product Key Operations with Forward Proxy

If the computer where Tableau Server is installed has been configured to connect with a forward proxy server, then you must run the procedure in this topic to activate, refresh, or deactivate product keys for Tableau Server.

Alternatively, you can activate a product key offline, see [Activate Tableau Server Offline](#).

To access and subsequently configure product key information for your Tableau Server installation, the Windows service, **Tableau Server Administrative Controller**, must run under the Run As service account. For normal operation, this service runs under the Network Service system account. This procedure describes how to specify the Run As service account as the temporary account used to log on for the **Tableau Server Administrative Controller** service. After you have successfully run the product key operation, you must then change the log on credentials back to the Network Service system account.

Before you begin

- If you are running a distributed deployment of Tableau Server, run the procedure in this topic on the initial node in the cluster.
- To run this procedure, you must know the Run As service account name and password. See [Change the Run As Service Account](#).
- Review your forward proxy configuration. The procedures below are for organizations that have set up the forward proxy using the "Internet Properties" on the Windows computer where Tableau Server is running. See [Configuring Proxies and Load Balancers for Tableau Server](#).

Step 1: Verify proxy configuration

1. Log onto the computer where Tableau Server is installed or will be installed.
2. Open the **Local Area Network (LAN) Settings** dialog box. (A quick way to get to this dialog box is to search for `Internet Options` in the Windows Start menu. In the **Internet Properties** dialog box, click the **Connections** tab, and then click **LAN settings**.)
3. Under **Proxy server**, verify that **Use a proxy server for your LAN** is selected and that the proxy server address and port has been specified.

Step 2: Temporarily change log on account for Tableau Server Administrative Controller service

1. Log onto the same computer that you verified in Step 1 above,
2. Open the **Services (Local)** Microsoft Management Console. (A quick way to get to this console is to search for `Services` in the Windows Start menu.)
3. Right-click **Tableau Server Administrative Controller**, click **Properties**. On **Tableau Server Administrative Controller Properties** page, click the **Log On** tab.
4. On the **Log On** tab, change `Network Service` to your Run As service account. Enter the password and then click **OK**.
5. In the **Services (Local)** Microsoft Management Console, right-click **Tableau Server Administrative Controller**, and then click **Restart**.

Step 3: Activate, refresh, or deactivate Tableau product keys

While the Tableau Server Administrative Controller is running under your Run As service account, you can activate, refresh, or deactivate your Tableau product key.

- To activate as part of the setup process, see [Activate and Register Tableau Server](#).
- To refresh a product key, see [Refresh Expiration Date and Attributes for the Product Key](#).
- To deactivate a product key, see [tsm licenses deactivate](#).

Step 4: Revert the log on account back to Network Service

After you have completed your product key operation, you must change the log on account for Tableau Server Administrative Controller back to the `Network Service` account.

1. Open the **Services (Local)** Microsoft Management Console.
2. Right-click **Tableau Server Administrative Controller**, click **Properties**. On **Tableau Server Administrative Controller Properties** page, click the **Log On** tab.

3. On the **Log On** tab, click the **Browse** button.
4. On the **Select User** dialog box, enter `Network Service`, and then click **OK** to resolve the name and return to the **Log On** tab.
5. On the **Log On** tab, clear the passwords from the `Network Service` account, and then click **OK**.
6. In the **Services (Local)** Microsoft Management Console, right-click **Tableau Server Administrative Controller**, and then click **Restart**.

Configure Initial Node Settings

This topic describes how to configure essential server settings as part of the initial Tableau Server installation process.

Prerequisite

Before proceeding with the procedures in this topic, complete the following prerequisites as outlined in *Install and Configure Tableau Server*:

- Install TSM
- Activate and Register Tableau Server

Use the TSM web interface

After you have activated and registered Tableau Server, the installation program will display the Setup page.

Note: If you need to configure Tableau Server to connect to an LDAP directory that is not Active Directory, then you must use the TSM CLI.

The settings below are all you need to get started.

Identity Store

You cannot change the identity store after initializing.

- ☐ Local
☐ Active Directory

Run As Service Account

- ☒ NT AUTHORITY\NetworkService
☐ User Account

Gateway Port

Port Number: (Default)

Product Usage Data

- ☐ Disable sending usage data to Tableau

Include samples

- ☒ Include sample workbooks

Initialize

Identity store settings

You must configure the identity store settings for the Tableau Server computer. The identity store manages Tableau Server accounts. You can configure the identity store to synchronize with an external directory (for example, OpenLDAP or Active Directory) or you can configure the identity store to manage and store accounts on Tableau Server. If you will be using a single sign on solution (OpenID, SAML, Kerberos, etc) then review the following topics before configuring the identity store:

- Identity Store
- Authentication

Important: After you have configured and applied settings for the identity store, it cannot be changed.

Identity Store

You cannot change the identity store after initializing.

☐ Local

☒ Active Directory

Domain	NetBIOS (Nickname)
<input type="text" value="example.lan"/>	<input type="text" value="EXAMPLE"/>

☐ Allow unencrypted communication with Active Directory if an encrypted session cannot be established (Not recommended)

If you select **Active Directory**, Tableau Server will populate the **Domain** and **NetBIOS** fields from the computer on which you are running Setup. In some cases, Setup may not display these attributes. For more information about how Tableau Server connects and communicates with Active Directory, see *User Management in Deployments with External Identity Stores*.

Allow unencrypted communications with Active Directory

Your Active Directory infrastructure should manage certificates and trust with domain-joined computers. As such, the channel communication between Tableau Server and Active Directory resources should be encrypted. By default, Tableau Server requires an encrypted channel to Active Directory. We do not recommend allowing unencrypted communications with Active Directory, as this configuration is vulnerable to man-in-the-middle attacks. However, in some deployment scenarios, organizations do not encrypt the channel during initial configuration. Should you need to temporarily allow unencrypted communication with Active Directory, you can re-enable enforcement of encrypted communication later by running the tsm command, `wgserver.domain.allow_insecure_connection`, or by logging into TSM UI and toggling the setting under **User Identity & Access > Identity Store**.

Run As service account

By default, Tableau Server runs under the Network Service account. To use an account that will accommodate NT authentication with data sources, specify a user name and password. See *Run As Service Account* to learn more about creating and using a specific user account.

Important: Include the domain name with the user name—for example, `example\tableaurunas`.

Enter the password that you created for this account.

The image shows a 'Run As Service Account' dialog box. It has two radio buttons: 'NT AUTHORITY\NetworkService' (unselected) and 'User Account' (selected). Below the radio buttons are two text fields: 'Username' and 'Password'. The 'Username' field contains the text 'example\tableaurunas'. The 'Password' field is filled with dots, indicating a masked password.

Gateway port

The default port for web access to Tableau Server (via HTTP) is port 80. If the installation program determines that port 80 is in use when you first install Tableau Server, an alternate port (for example 8000) is used and shown in the Port number box.

You may need to change the port for other networking needs, for example, if you have a hardware firewall or proxy in front of the Tableau Server host, this might make running a back-end system on port 80 undesirable.

The image shows a 'Gateway Port' dialog box. It contains a label 'Port Number:' followed by the value '80' and the text '(Default)' in parentheses.

Product usage data

By default, Tableau Server shares usage data with Tableau that helps us better understand how you use our products, improve your overall experience, and build highly intelligent features that make Tableau even more powerful.

Clear this option if you do not want usage data sent to Tableau.

Product Usage Data
☐ Disable sending usage data to Tableau

You can also change this setting after installation, on the TSM Maintenance tab in the TSM Web UI, or using the TSM CLI. For more information, see [Server Usage Data](#).

Sample workbook installation

By default, Tableau Server will install sample workbooks in the Default site when you initialize the server.

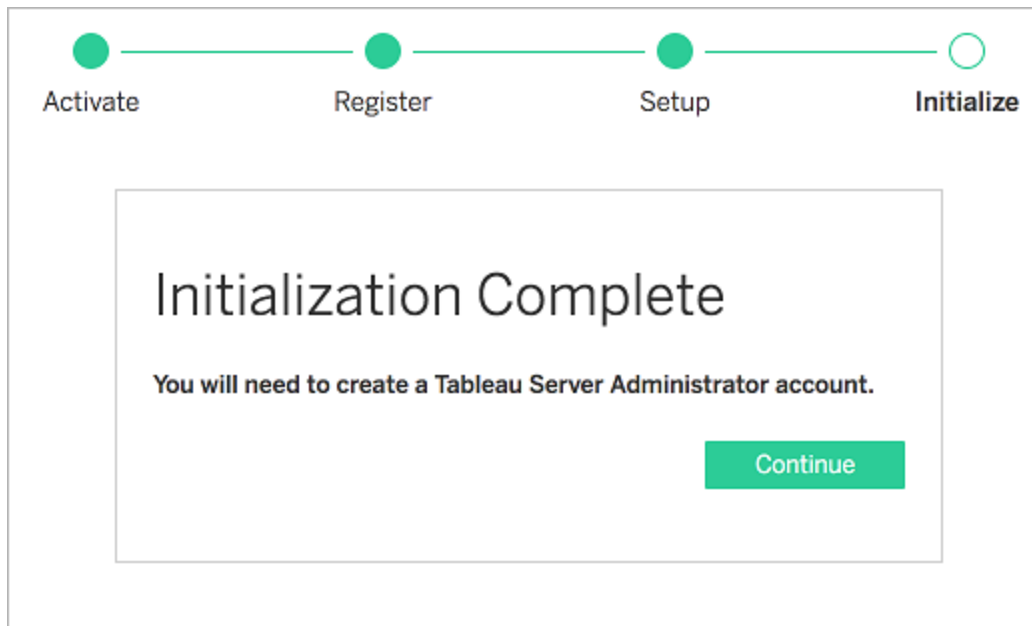

Include samples
☒ Include sample workbooks

Alternatively, you can publish samples after installation by using the `publishsamples tabcmd` command.

Initializing install

After you have configured the options on this page, click **Initialize**.

The initialization process can take a while. When initialization is complete the following page is displayed:

Use the TSM CLI

First, configure identity store, gateway settings, and sample workbook installation. Then apply the changes, optionally verify your LDAP connection, and then initialize Tableau Server

Configure identity store settings

You must configure the identity store settings for the Tableau Server computer.

Important: After you have configured and applied settings for the identity store, it cannot be changed.

Use the json template in identityStore Entity to create a json file. After you have filled in the options with the appropriate values, you can then pass the json file with this command:

```
tsm settings import -f path-to-file.json.
```

Configure gateway settings (optional)

Depending on your network requirements, you may need to configure the gateway settings for the Tableau Server computer. For example, if you are enabling SSL or configuring access to Tableau Server with a reverse proxy, you may need to configure gateway settings. See `gatewaySettings` Entity for more information.

Use the json template in `gatewaySettings` Entity to create a json file. After you have filled in the options with the appropriate values, you can then pass the json file with this command:

```
tsm settings import -f path-to-json-file.json.
```

Configure product usage data (optional)

By default, Tableau Server shares usage data with Tableau to help us better understand how you use our products. This allows us to improve your overall experience and build highly intelligent features that make Tableau even more powerful.

Tableau collects only behavioral and usage data, never any of your confidential database values, and your usage data will never be shared or sold; its sole purpose is to improve your Tableau experience.

If you do not want to share product usage data, use the json template in `shareProductUsageDataSettings` Entity to create a json file, and specify a value of `false`. Then pass the json file with this command:

```
tsm settings import -f path-to-json-file.json.
```

You can also change this setting after installation, on the TSM Maintenance tab or using the TSM CLI. For more information, see [Server Usage Data](#).

Configure sample workbook installation (optional)

By default, Tableau Server will install sample workbooks in the Default site when you initialize the server.

If you do not want to install sample workbooks during installation, run the following command:

Tableau Server on Windows Help

```
tsm configuration set -k install.component.samples -v false
```

You can publish samples after installation by using the `publishsamples tabcmd` command.

Apply pending configuration changes

Now that you've created and set initial configuration, you must apply them. When you apply configuration changes, `tsm` will verify the settings you've set before committing them.

To apply configuration changes to Tableau Server, run this command:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Once this command has completed, TSM processes are running, and Tableau Server is configured but is not running.

Verify LDAP configuration (Optional)

If your identity store uses LDAP, then we recommend verifying LDAP connectivity before proceeding.

To do so, run the following commands before you initialize the server:

```
tsm user-identity-store verify-user-mappings -v <user name>
```

```
tsm user-identity-store verify-group-mappings -v <group name>
```

User and group names must be valid names that exist in the LDAP server that you are connecting to. If your LDAP connection is set up correctly, then the user or group attributes will be returned to the shell. If your connection is not set up correctly, then an error will be returned.

Initialize and start Tableau Server

- To initialize and start Tableau Server, use the `--start-server` option:

```
tsm initialize --start-server --request-timeout 1800
```

This saves time by starting the server running after initialization.

- If you are going to reconfigure Tableau Server after initialization, leave the `--start-server` option off:

```
tsm initialize --request-timeout 1800
```

This stops the server after initialization.

Start Tableau Server. If you did not use the `--start-server` option during initialization and are finished configuring Tableau Server, use this command to start the server:

```
tsm start --request-timeout 900
```

Next Step

After initialization is complete, create the Tableau Server administrator user account. See [Add an Administrator Account](#).

Configuration File Example

This article provides an example of a complete JSON configuration file, with `gatewaySettings` and `identityStore` entities specified. In addition, a configuration key sets the gateway timeout to 900 seconds.

Your configuration file will look different depending on the options you need to set.

You might set multiple .json configuration files during installation. To set the values for each file in Tableau Server, you run the following command, once for each configuration file:

```
tsm settings import -f path-to-file.json
```

After you set the configuration files, run `tsm pending-changes apply` to apply the changes from all of the `.json` files you've set.

```
{
  "configEntities": {
    "gatewaySettings": {
      "_type": "gatewaySettingsType",
      "port": 80,
      "publicHost": "localhost",
      "publicPort": 80
    },
    "identityStore": {
      "_type": "identityStoreType",
      "type": "local",
      "domain": "example.lan",
      "nickname": "EXAMPLE"
    }
  },
  "configKeys": {
    "gateway.timeout": "900"
  }
}
```

Entities vs keys

As shown in the example above, there are two classes of configuration parameters: `configEntities` and `configKeys`.

configEntities

Certain types of configuration are done through entity sets that map to specific scenarios, such as the identity store and gateway configurations. When you pass a set of `configEntities` with the `tsm settings import -f path-to-file.json` command, TSM validates the configuration. If values passed are invalid, TSM will provide an error. This enables you to make changes during the configuration process, rather than experience a configuration failure at initialization or run time.

Entities can be set only by including a configEntities block in a .json file.

Important: All files that are referenced in configEntities must be located on the local computer. Do not specify UNC paths.

configKeys

Entities cover only a small portion of the configuration values that can be set. Hundreds of keys correspond to parameters stored in .yaml files. Tableau Server uses these parameters to store all of the configuration information for all services.

You can set individual keys with the tsm configuration command. But during deployment, setting them along with other configuration scenarios in JSON files, as shown above, is more convenient.

Unlike configEntities, configKeys are not validated.

Note: We do not recommend setting parameters that are not documented in tsm configuration set Options.

Server Usage Data

The Tableau Server administrator can control whether or not usage data from Tableau Server is sent to Tableau. By default this option is enabled, and can be disabled at initial install, or after installing Tableau Server, using the TSM Web UI or command line. For details about this usage data, see [Tableau Product Usage Data](#).

In addition to product usage data, Tableau products send Basic Product Data to Tableau. This data is sent whether or not you have disabled the sending of product usage data. You can disable the sending of Basic Product Data separately. For details, see Basic Product Data.

Tableau Server on Windows Help

Disable Usage Data Sharing

You can disable the sharing of usage data when you install Tableau Server, or at any time after installation.

Disabling the sharing of usage data at install

To disable the sharing of usage data with Tableau when you are installing Tableau Server, clear the option during the initial configuration of server. For details, see [Product usage data](#).

Disabling the sharing of usage data after install

Use the TSM web interface

1. Open TSM in a browser:

<https://<tsm-computer-name>:8850>. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Maintenance** tab.
3. Under Other Maintenance Tasks, in Server Usage Data, clear **Send usage data to improve Tableau features**:

Product Usage Data

Help us improve your Tableau experience by sharing how you use the product. Tableau collects information about your feature usage. All usage data will be handled according to our Privacy Policy - <http://www.tableau.com/privacy>

[Learn more](#)

☐ Disable sending usage data to Tableau

4. When you are finished, click **Pending Changes**, and then click **Apply Changes and Restart**.

Use the TSM CLI

If you do not want to share product usage data, disable the option using this tsm configuration command:

```
tsm configuration set -k shareproductusagedata.enabled -v false  
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Basic Product Data

By default Tableau products send usage data to Tableau so that we can understand how customers use our software, and gain insights into where they are successful and where they might run into problems that we can address. For example, this data can help us learn where upgrades are commonly failing and allow us to make product changes to address those issues, or identify what portion of our user base needs informed about a security issue that applies to a specific version of Tableau Server. You can disable the sending of this data at installation time, or later. For details on how to do this, see the instructions for [Tableau Desktop](#) or [Tableau Server](#).

Even when you disable the sending of product usage data, certain basic product data is sent to Tableau. This Basic Product Data includes information about products and their processes, including which product or process is running, when they start up, what operating system they are running on, licensing information, which machine or cluster of machines has sent the data (using unique pseudonymized identifiers), and whether the product is configured to send product usage data.

You can disable the sending of Basic Product Data at the machine level, or at the enterprise level, by blocking traffic sent to **prod.telemetry.tableausoftware.com**.

Disabling sharing of Basic Product Data on individual computers

Important: This procedure involves modifying your local `hosts` file. If you do not know what this is, you should not change it. You should only make this change if you understand the implications of making changes to the file, know how to change the file, and have made a backup of the file for safety.

Modifying `hosts` files changes network behavior for computers. Detailed instructions for modifying `hosts` files are provided by operating system providers such as Microsoft, Apple or Linux Distributions.

1. Make a copy of your existing `hosts` file and save it to a computer that is not your Tableau computer. This is your backup, in case you need to reverse your changes. Do not start modifying the file until you have made a backup copy of it.
2. Modify your computer's `hosts` file to include these lines:

```
# Stops sending Product Usage to Tableau (prod.telemetry.tableausoftware.com).  
# Learn more here: http:\\tableau.com\\derived-data  
127.0.0.1    prod.telemetry.tableausoftware.com
```

The first and second lines are comments, explaining the third line.

The third line prevents all traffic to `prod.telemetry.tableausoftware.com` (`http://prod.telemetry.tableausoftware.com/`) from leaving your local machine by sending it to the Internal host loopback address. The data does not get sent outside the computer.

Disabling the sharing of Basic Product Data at the enterprise level

To disable sending of Basic Product Data on an enterprise level, modify your Network Firewall to prevent outbound traffic to `prod.telemetry.tableausoftware.com`.

This domain is used by Tableau to receive the Basic Product Data about process launch and shutdown. It is also used for the more general Product Usage Data. Blocking traffic to this domain it you will prevent both kinds of data from being sent.

Traffic to this domain will occur on Ports 80 (for initial registration of our Product Data clients) and on Port 443 (for all subsequent traffic). To completely prevent product data from being sent, block all traffic to this domain.

For details on how to configure your network firewall, refer to your vendor or your internal IT department. Tableau cannot provide these instructions.

Add an Administrator Account

The final step in activating Tableau Server is to add the initial administrator account. The administrator will have all access to the server including the ability to manage users, groups, and projects.

The server must be running when you create the initial admin user.

If you have configured the Tableau Server identity store to use LDAP or Active Directory, then the initial administrative user that you specify must be an account in the directory. The initial administrative user is generally distinct from the user account on the Tableau Server computer that you use to run `t-sm`.

However, these accounts can be the same if you have configured the Tableau Server identity store to use Active Directory and the initial admin user is a member of the local administrator group on the Tableau Server computer.

Prerequisites

Before proceeding with the procedures in this topic, complete the following prerequisites as outlined in *Install and Configure Tableau Server*:

- Install TSM
- Activate and Register Tableau Server

- Configure Initial Node Settings

Use web UI

After Tableau Server is finished initializing, the installation program will display a page to create the Tableau Server administrator.

- If you configured a local identity store during setup, then specify a name and password that you want to use.
- If you configured a LDAP or Active Directory identity store during setup, then you must specify a user account that is a member of the directory.
- The `username` value cannot include an at sign (@) unless the user name suffix matches Tableau Server's primary domain. For example, if Tableau Server connects to domain "myco.com", a user name of "user@example.com@myco.com" cannot be used.

If you are installing remotely, then you must sign in to TSM on the physical computer where Tableau Server is installing, or you can access the computer remotely and run the `tabcmd initialuser` command from a shell.

Use tabcmd CLI

You must create the initial administrative account for Tableau Server.

- If you configured a local identity store during setup, then specify a name and password that you want to use.
- If you configured a LDAP or Active Directory identity store during setup, then you must specify a user account that is a member of the directory.
- The `username` value cannot include an at sign (@) unless the user name suffix matches Tableau Server's primary domain. For example, if Tableau Server connects to domain "myco.com", a user name of "user@example.com@myco.com" cannot be used.

To create the initial user, run the following `tabcmd` command:

```
tabcmd initialuser --server http://localhost --username "<new-  
admin-username>"
```

For example:

```
tabcmd initialuser --server http://localhost --username "tableau-  
admin"
```

If you are running the HTTP protocol on a port other than 80, specify the port after the host name, for example: `--server http://localhost:8080`.

After you run the command, the shell will prompt for an administrative password.

Next steps

After you have created the Tableau Server administrator account, continue your deployment by working through the configuration topics at Post Installation Tasks.

Initial Node Installation Defaults

By default, the Tableau Server installer configures the number of process instances that Tableau Server runs based on the hardware detected by the installer. The default configuration applies to single-server installations and to the initial server of a multi-node installation.

You can calculate the default configuration based on the following rules for each process, where the "number of cores" refers to the number of physical processors:

Process Name	Number of Processes
VizQL Server	Equal to the number of cores divided by four, up to a maximum of four process instances.
Backgrounder	Set to two unless the number of cores is fewer than eight.
Cache Server	Set to two unless the number of cores is fewer than eight.
Data Server	Set to two unless the number of cores is fewer than eight.

For all other process types, the number of process instances is set to one, regardless of the hardware.

Here's an example default configuration for a computer with 16 cores:

Process Name	Number of Processes
VizQL Server	4
Application Server	1
Backgrounder	2
Cache Server	2
Data Server	2
File Store	1
Data Engine	1

Jump-start Installation

This topic provides all of the steps required to perform a basic, quick-start installation of Tableau Server. The purpose of the configuration described here is to provide the quickest, simplest path to a Tableau Server installation. Use this procedure as practice, to try out the Tableau Server installation, management, and user experience before your actual server deployment.

Important: Do not use this procedure as a stand-alone resource for deploying Tableau Server into a production environment. To deploy Tableau Server into a production environment, refer to the content at [Install and Configure Tableau Server](#).

The procedures in this topic will install an instance of Tableau Server for Windows using a local identity store.

Before you begin

Review the topic, [Before you install....](#) The procedure here assumes that you have installed Windows on conforming hardware and according to the environmental requirements specified in that topic.

Note that the computer you install on must meet the minimum hardware requirements specified in [Minimum Hardware Requirements and Recommendations for Tableau Server](#). The setup program will not install Tableau Server onto systems that do not meet the minimum hardware requirements.

Step 1: Install Tableau Server and start Tableau Services Manager

1. Double-click the installation file.
2. Follow the on-screen instructions to complete Setup and install the application.

The default installation path is `C:\Program Files\Tableau\Tableau Server`. You can choose a different location, including a different drive, either by browsing to or typing in a new path.

If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

3. Click **Next**.

On the **Server installation type** page, you can specify whether you are installing the first node of a Server installation, or additional nodes in a multi-node installation. You do not need to change this from the default (Create new Tableau Server installation.) unless you are installing a multi-node Tableau Server. If you are installing a multi-node Tableau Server, see [Install and Configure Additional Nodes](#).

4. Click **Next**.

On the **Product Activation Type** page, select whether you want to use the authorization-to-run (ATR) service to activate Tableau Server, and then click **Install**.

5. After the installation completes, click **Finish**. Setup will then open the TSM configuration web page on the computer where you are installing Tableau Server.

Step 2: Activate and register Tableau Server

Before you can configure Tableau Server you must activate a license and register. For more details, see [Activate and Register Tableau Server](#).

1. Sign in to Tableau Services Manager Web UI.
2. On the **Activate** page, enter or paste your product key and click **Activate Product Key**.

After your product key is activated, it appears under **Activated Product Keys**.

3. To activate another product key, enter the new product key, and then click **Activate Product Key**. After your product key is activated, it appears under **Activated Product Keys**.
4. When you're finished activating product keys, click **Next**.

Note: If the product keys you have activated don't have the necessary capacity, such as not enough cores or only a Viewer role product key, Tableau Services Manager displays the **Insufficient licenses applied** dialog box. Click **Activate Another Product Key** to add another product key and increase capacity on your Tableau Server installation.

Tableau Server on Windows Help

Insufficient licenses applied

You have not activated enough product keys for your Tableau Server deployment.

If you try to activate Tableau Server using these licenses, it may not run properly. We recommend that you activate additional licenses to support this Tableau Server deployment

[Tableau Customer Portal](#)
[Troubleshooting](#)

[Activate Another Product Key](#)

5. On the **Register** page, enter your information into the fields and click **Register**.

Register with Tableau. All fields are required.

Contact Information

First Name	Last Name
<input type="text"/>	<input type="text"/>
Phone Number	Email
<input type="text"/>	<input type="text"/>

Company Information

Organization	
<input type="text"/>	
Industry	Company Size
<input type="text"/>	<input type="text"/>
Department	Job Role
<input type="text"/>	<input type="text"/>

Region Information

City	Postal Code
<input type="text"/>	<input type="text"/>
Country/Region	State/Province
<input type="text"/>	<input type="text"/>

Step 3: Configure local identity store

You must configure the identity store settings. This procedure simplifies installation by setting the identity store to local authentication. For more details on customizing these defaults, see [Configure Initial Node Settings](#).

The settings below are all you need to get started.

Identity Store

You cannot change the identity store after initializing.

- ☐ Local
- ☐ Active Directory

Run As Service Account

- ☒ NT AUTHORITY\NetworkService
- ☐ User Account

Gateway Port

Port Number: (Default)

Product Usage Data

- ☐ Disable sending usage data to Tableau

Include samples

- ☒ Include sample workbooks

Initialize

After you have configured the options on this page, click **Initialize**.

The initialization process can take a while. When initialization is complete the following page is displayed:

Step 4: Add administrator account

The final step in activating Tableau Server is to add the initial administrator account. The administrator will have all access to the server including the ability to manage users, groups, and projects. More details are at [Add an Administrator Account](#).

After Tableau Server is finished initializing, the installation program will display a page to create the Tableau Server administrator.

Specify a name and password that you want to use for the administrative account.

If you are installing remotely, then you must sign in to TSM on the physical computer where Tableau Server is installing, or you can connect remotely to the computer and run the `tabcmd initialuser` command from a shell.

Use the administrator account that you created in this step to access the Tableau Server admin web pages. See [Sign in to the Tableau Server Admin Area](#).

Step 5: Validate your installation

This is an optional step, but a good way to validate that Tableau Server is installed and running properly is to look at the built-in Administrative Views in Tableau Server.

Install Switches and Properties for Tableau Server

You can use the following installer switches when installing Tableau Server on Windows from the command line.

Switch	Description	Comments
<code>/install /repair /uninstall /layout "<directory>"</code>	Run Setup to either install, repair, or uninstall Tableau Server, or with <code>/layout</code> , create a complete local copy of the installation bundle in the directory specified.	Default is to install, displaying UI and all prompts. If no directory is specified on a fresh install, <code>C:\Program Files\Tableau\Tableau Server</code> is assumed. If Tableau Server is already installed, Setup will assume the same location as the current installation.
<code>/passive</code>	Run Setup with minimal UI and no prompts.	Tableau Server does not start automatically when installed in <code>/passive</code> mode. To start Tableau Server, use <code>tsm start</code> .
<code>/quiet /silent</code>	Run Setup in unattended, fully silent mode. No UI or prompts are displayed.	Tableau Server does not start automatically when installed in <code>/silent</code> or <code>/quiet</code> mode. To start Tableau Server, use <code>tsm start</code> .

	played.	Note: Use either <code>/silent</code> or <code>/quiet</code> , not both.
<code>/norestart</code>	Run Setup without restarting Windows, even if a restart is necessary.	Note: In certain rare cases, a restart cannot be suppressed, even when this option is used. This is most likely when an earlier system restart was skipped, for example, during installation of other software.
<code>/log "<drive>\<path>\<log-file>.<ext>"</code>	<p>Log information to the specified file and path.</p> <p>Note: The behavior when using the <code>/log</code> option changed starting in version 2021.2.0. For more information, see Tableau Server Release Notes.</p>	<p>Use this switch with a path and log file name to make the log available after installation is complete.</p> <p>If this switch is used with a log file name but no path, the log file is written to a temporary location and deleted at the end of the installation.</p> <p>If this switch is used but no log file name is specified, the switch is ignored and the file is written to <code>%TEMP%</code>.</p> <p>If this switch is not used, the log file is written to <code>%TEMP%</code>.</p>

Properties	Description	Comments
ACCEPTEULA=1 0	Accept the End User License Agreement (EULA). Required for quiet, silent, and passive install on both initial and additional nodes. 1 = true, accept the EULA, 0 = false, do not accept the EULA.	<p>If not included when using <code>/passive</code>, <code>/silent</code> or <code>/quiet</code>, Setup fails silently.</p> <p>If included but set to 0, Setup fails.</p>
ACTIVATIONSERVICE-E="1" "0"	Activate Tableau Server using the authorization-to-run (ATR) service. "1" = use Server ATR. "0" = don't use Server ATR.	<p>This option is for new installs only, not upgrades. Select this option if:</p> <ul style="list-style-type: none"> • You plan to activate Tableau Server online • You plan to install Tableau Server in the cloud • You plan to install Tableau Server on a virtual machine or other non-persistent environment <p>Do not use this option if:</p> <ul style="list-style-type: none"> • You plan to activate Tableau Server offline • You plan to install Tableau Server in an air-gapped environment <p>For more information, see Activate Tableau Server Using the Author-</p>

		ization-To-Run (ATR) Service.
BOOTSTRAPFILE= =<path\to- o\bootstrap\file>"	Required when adding a node to a cluster. The bootstrap file contains the configuration used by additional nodes.	Example: <Setup file> /silent ACCEPTTEULA=1 BOOTSTRAPFILE= ="C:\Use- rs\t- ableau- admin\Down- loads\bootstrap.json"
CONTROLLERPORT=	Optional. The port on which the Tableau Services Manager (TSM) Controller should run.	If not included, defaults to 8850.
COORDINATIONSERVICECLIENTPORT=	Optional. The port on which the Tableau Services Manager (TSM) Coordination Service client should run.	If not included, defaults to a dynamically mapped port. For more information, see Tableau Services Manager Ports.
COORDINATIONSERVICEPEERPORT=	Optional. The port on which the Tableau Services Manager (TSM) Coordination Service peer should run.	If not included, defaults to a dynamically mapped port. For more information, see Tableau Services Manager Ports.
COORDINATIONSERVICELEADERPORT=	Optional. The port on which the Tableau Services	If not included, defaults to a dynamically mapped port. For more information, see Tableau Services Manager Ports.

	Manager (TSM) Coordination Service Leader should run.	
DATADIR= <code>"<path\to\data-a\directory>"</code>	Optional. The location where the Tableau Server software configuration and data are stored. If you don't provide a data directory path and Tableau Server is being installed to the default location (INSTALLDIR is not specified), the default data directory is used: <code>C:\ProgramData\Tableau\Tableau Server</code> . If you don't provide a data directory path and INSTALLDIR is specified, DATADIR is also set to the INSTALLDIR location.	Example: DATADIR= <code>R="D:\TableauServerData"</code>

<p>EMBEDDED CREDENTIAL=1 0</p>	<p>Required when adding a node to a cluster and the bootstrap file contains the embedded credentials of an administrator on the TSM computer.</p> <p>1=true, 0=false. Default is 0.</p>	<p>Must be used with <code>/silent</code> or <code>/quiet</code> and with <code>BOOTSTRAPFILE</code></p> <p>Example: <code><Setup file> /silent ACCEPTTEULA=1 BOOTSTRAPFILE="C:\Users\tableau-admin\Downloads\bootstrap.json" EMBEDDED CREDENTIAL=1</code></p>
<p>INSTALLDIR="<code><path\to\installation\directory></code>"</p>	<p>Install to the specified non-default install location.</p>	<p>Specifies the location to install server. If not used, Tableau Server is installed to <code>C:\Program Files\Tableau\Tableau Server</code></p> <p>Example: <code><Setup file> /silent INSTALLDIR="D:\Tableau\Tableau Server"</code></p>
<p>LICENSESERVICEVENDOR-DAEMONPORT=</p>	<p>Optional. The port on which the License service vendor daemon should run. This is used in multi-node installations for licensing-related communication between nodes.</p>	<p>If not included, defaults to a dynamically mapped port. For more information, see Tableau Services Manager Ports.</p>

<code>SKIPPYTHONINSTALL- L=1 0</code> Added in version 2021.3.0	<p>Optional. If set to 0 (the default), the Setup program installs the included Python package. If set to 1, specifies that the Setup program should not install the Python package as part of Tableau Server.</p> <p>Note: Python will be used in future releases of Tableau Server to support advanced analytics features. If you choose to skip installation of Python, Tableau Server users will not have access to those advanced analytics features when those features are available.</p>	<p>If not included, defaults to installing Python as part of Tableau Server.</p>
--	---	--

Automated Installation of Tableau Server

You can use `SilentInstaller.py`, a **community supported** Python script, to automate a new install of Tableau Server. You can download the script and use it as written, or modify it for your specific needs.

Benefits of using the automated installer

- With a single command, you can install, configure, and run a working instance of Tableau Server.
- The `SilentInstaller.py` script can be run without user input making it suitable for automation.
- The configuration can be set once and used for all your installations, making this a repeatable process.

When not to use the automated installer

- If you are installing Tableau Server for the first time, we recommend that you manually test your installation before automating the process. Any issues that block installation are easier to resolve interactively. After you have resolved these issues, you can perform an automated installation of Tableau Server using the `SilentInstaller.py` script.
- If you are testing or trying new configuration parameters such as authentication methods, we recommend that you manually run the installation first. Tableau Services Manager (TSM) validates configuration entities and rejects configuration parameters that are not valid. Once you have the correct parameters identified, you can use the automated installer.
- If you are unable to or do not want to enter passwords into the secrets file, using the automated installer might not be an option for you.

Before you begin

Review [Before you install...](#) to make sure you have installed Microsoft Windows Server on a computer that meets the operating system requirements and the minimum hardware requirements for Tableau Server.

Note: If you are installing Tableau Server in a production environment, review the minimum hardware **recommendations**. The recommendations represent the minimum hardware configuration you should use for a production installation of Tableau Server.

To perform an automated installation, you use the `SilentInstaller.py` script, which relies on the Tableau Server install package as an input. Before you begin, we recommend that you download the following packages:

1. Download [Python 3.5](#) or later and install it on the computer where you want to install Tableau Server.
2. Download both the `SilentInstaller.py` script and the Tableau Server installer package:
 - a. Download the `SilentInstaller.py` script from [GitHub](#), along with `config.template.json`, `registration.template.json`, `secrets.template.json`, and the three bootstrap templates (`bootstrap.template.json`, `topologyBootstrap.template.json`, and `workerBootstrap.template.json`).
 - b. Select and download the appropriate **Tableau Server installer package** from the [Tableau Server Product Downloads](#) page. The one you choose depends on the version of Microsoft Windows Server you want to use.
3. Copy the packages and templates to a location on or accessible from the computer where you are going to install Tableau Server.

How to use the SilentInstaller.py script

The `SilentInstaller.py` script installs the Tableau Server installer package, creates the directories, sets the permissions required to run Tableau Server, and starts the Tableau Services Manager (TSM) setup. After TSM setup is complete, the `SilentInstaller.py` script runs `tsm` commands to install, configure, and start Tableau Server. By default, the `SilentInstaller.py` script activates a trial license during installation. If you have an actual product key, you can provide the product key at the command line or activate the product key after you run the `SilentInstaller.py` script. Most of the command line options in the automated installer are the same as the options used by the `tsm initialize` command.

You can run the `SilentInstaller.py` script in three modes: install the initial node, install additional nodes, and update cluster topology. When doing an installation for a distributed cluster, you'll run `SilentInstaller.py` with the options to install the initial node on the initial node. You'll run `SilentInstaller.py` with the options to install additional nodes on each additional node. Lastly, you'll run `SilentInstaller.py` with the options to update cluster topology on the initial node.

The `SilentInstaller.py` script is meant to be run without user interaction, so you must input all parameters into the required arguments that are passed to the `SilentInstaller.py` script. Alternatively, you can also put the required arguments into the bootstrap file. You can use the Configuration, registration, and secrets file templates provided.

Use the following steps to perform an unattended installation:

Step 1: Install the automated installer

1. Log onto the computer as a user with administrator access.
2. Download and install the `SilentInstaller.py` script, templates, and bootstrap files.

Step 2: Create files to provide additional configuration information required to run the automated install

Since the `SilentInstaller.py` script is meant to run without user interaction, you must provide the following additional information:

1. Copy the templates, **config.template.json**, **registration.template.json**, and **secrets.template.json**, to another directory like your home directory. We don't recommend that you edit the template files directly.
2. Edit the **config.template.json** file and provide the initial node configuration settings. You must provide identity store settings for the Tableau Server computer. Depending on your network requirements, you may need to also provide the gateway settings. The caching option is set to cache and reuse data for as long as possible. Sample workbooks are installed by default. The template includes the minimum required information, so the template is a starting point. For more information on configuration settings, see [Configure Initial Node Settings](#).
3. Edit the **registration.template.json** file and provide the information needed to register Tableau Server. For more information, see [Activate and Register Tableau Server](#).
4. Edit the **secrets.template.json** file and provide the user name and password for the TSM administrator and Tableau Server administrator accounts.
 - The TSM administrator account should be the same user as the Windows administrator running the script.
 - The Tableau Server administrator account is the initial account that is created by the installer and is used to administer Tableau Server.

Step 3: Run the automated install

1. Log onto the computer as a user with administrator access.

Install the initial node

The `SilentInstaller.py` script runs the proper commands to install, activate license, configure, and start Tableau Services Manager. Run `SilentInstaller.py -h` and `SilentInstaller.py install -h` to see the full list of options and their default values.

To install the initial node:

On the initial node, at a Python prompt, type:

```
SilentInstaller.py install --secretsFile secrets.json --con-
figFile myconfig.json --registrationFile registration.json
TableauServer-64bit-<version>.exe
```

Or alternatively:

```
SilentInstaller.py --bootstrapFile <bootstrap file path>
```

Script Option	Description
Required switches	
<code>--configFile <file path></code>	The relative or absolute path to the Server Configuration JSON file.
<code>--secretsFile <file path></code>	The relative or absolute path to the Secrets File that describes the credentials of the Windows account to authenticate to Tableau Services Manager (TSM), and the username/password of the initial administrator user for Tableau Server. The secrets file also includes the product key

Script Option	Description
	<p>you want to use to activate Tableau Server. By default, the secrets file template contains a trial license.</p> <div> <p>Note: Providing the password in the secrets file is optional. However, if passwords are not found in the secrets file, you will be prompted to provide them during installation.</p> </div> <p>The automated installer package includes the template for the secrets file.</p>
--registrationFile <file path>	<p>The relative or absolute path to the Server Registration file containing the Tableau Server registration information.</p> <p>The automated installer package includes the template for the registration file.</p>
<installer executable file path>	The relative or absolute path to the Tableau Services Manager (TSM) installer.
Optional switches	
--installDir <file path>	The Tableau Server installation directory. If you don't provide a path, the default directory C:\Program Files\Tableau\Tableau Server will be used.
--dataDir <file path>	The location where the Tableau Server software

Script Option	Description
	configuration and data are stored. If you don't provide a path, the default directory C:\ProgramData\Tableau is used for the configuration and data files.
--installerLog <file path>	The existing directory where the installer's log files are written. If you don't provide a path, the log files will be written to your TEMP directory.
--controllerPort <port number>	The port on which the Tableau Services Manager (TSM) Controller should run.
--coordinationServiceClientPort <port number>	The ZooKeeper client port.
--coordinationServicePeerPort <port number>	The ZooKeeper peer port.
--coordinationServiceLeaderPort <port number>	The ZooKeeper leader port.
--start	Whether the server should be started when setup is complete.

Install additional nodes

The `SilentInstaller.py` script runs the proper commands to install Tableau Services Manager (TSM) on the additional node. Run `SilentInstaller.py installWorker -h` to see the full list of options and their default values.

To install additional nodes:

On each additional node, at a Python prompt, type:

```
SilentInstaller.py workerInstall --secretsFile secrets.json --
nodeConfigurationFile nodeConfiguration.json TableauServer-
64bit-<version>.exe
```

Option	Description
<code>--secretsFile <file path></code>	<p>Required. The relative or absolute path to the Secrets File that describes the credentials of the Windows account to authenticate to Tableau Services Manager (TSM), and the username/password of the initial administrator user for Tableau Server. The secrets file also includes the product key you want to use to activate Tableau Server. By default, the secrets file template contains a trial license.</p> <div> <p>Note: Providing the password in the secrets file is optional. However, if passwords are not found in the secrets file, you will be prompted to provide them during installation.</p> </div> <p>The automated installer package includes the template for the secrets file.</p>
<code>--nodeConfigurationFile <file path></code>	Required. Path to the node configuration file for installing the additional node.
(installer executable) <file path>	<p>Required. The final argument to the script is simply the path, absolute or relative, to the Tableau Services Manager installer executable, acquired through usual channels such as downloaded from the Tableau Website.</p> <p>This script is only supported for use with Tableau Ser-</p>

Option	Description
	vices Manager.
<code>--installDir <file path></code>	Optional. The Tableau Server installation directory. If blank, the default directory C:\Program Files\Tableau\Tableau Server will be used.
<code>--dataDir <file path></code>	Optional. The location where the Tableau Server software configuration and data are stored. If blank, the default directory C:\ProgramData\Tableau is used for the configuration and data files.
<code>--installerLog <file path></code>	Optional. The existing directory where the installer's log files are written. If blank, the log files will be written to the user's TEMP directory.

Note: The node configuration file is automatically saved after installing the first node using `SilentInstaller.py`. You can find it under the working directory of the script.

Update cluster topology

The `SilentInstaller.py` script runs the proper commands to update the cluster topology as desired for Tableau Services Manager (TSM). Run `SilentInstaller.py updateTopology -h` to see the full list of options and their default values.

To update cluster topology:

On the initial node, at a Python prompt, type:

```
SilentInstaller.py updateTopology --secretsFile secrets.json --
configFile myconfig.json
```

Option	Description
--secretsFile <file path>	<p>Required. The relative or absolute path to the Secrets File that describes the credentials of the Windows account to authenticate to Tableau Services Manager (TSM), and the username/password of the initial administrator user for Tableau Server. The secrets file also includes the product key you want to use to activate Tableau Server. By default, the secrets file template contains a trial license.</p> <div> <p>Note: Providing the password in the secrets file is optional. However, if passwords are not found in the secrets file, you will be prompted to provide them during installation.</p> </div> <p>The automated installer package includes the template for the secrets file.</p>
--configFile <file path>	<p>Required. The relative or absolute path to the Server Topology file describing the Tableau Server topology to update. Only the topologyVersion part of the file will be applied, other configurations will be ignored.</p>

Configuration, registration, and secrets file templates

You can use the following example templates to pass data to the `SilentInstaller.py` script.

Secrets file template example

```
{
  "local_admin_user": "",
  "local_admin_pass": "",
  "content_admin_user": "",
  "content_admin_pass": "",
  "product_keys": ["trial"]
}
```

The `local_admin_user` is the Windows account to authenticate to the Tableau Services Manager.

The `content_admin_user` is the initial administrative user, who acts as a superuser for all of Tableau Server with respect to creating and managing users, sites, etc.

When installing additional nodes or updating the cluster topology, these credentials are ignored because the initial admin user was already created when the initial node was installed.

The `product_keys` is the key used to activate Tableau Services Manager. If multiple keys are specified, they will be activated one by one. In the case of non-install mode, these keys are ignored because the licenses have already been activated.

Server Configuration file template example

```
{
  "configEntities": {
    "runAsUser": {
      "_type": "runAsUserType",
      "name": "NT AUTHORITY\\NetworkService"
    },
    "gatewaySettings": {
      "_type": "gatewaySettingsType",
      "port": 80,

```

```

    "firewallOpeningEnabled":true,
    "sslRedirectEnabled":true,
    "publicHost":"*****replace me*****",
    "publicPort":80,
    "sslEnabled":false,
    "sslPort":443
  },
  "identityStore":{
    "_type":"identityStoreType",
    "type":"local",
    "domain":"*****Domain Name Here*****",
    "nickname":"*****Domain Nickname Here*****"
  }
},
"topologyVersion":{
  "nodes":{
    "****insert nodeId (lowercase) here****": {
      "services": {
        "filestore": {
          "instances":[
            {
              "instanceId":"0"
            }
          ]
        },
        "tabadmincontroller": {
          "instances":[
            {
              "instanceId":"0"
            }
          ]
        }
      }
    }
  }
}

```

```
    },
    "clientfileservice": {
        "instances":[
            {
                "instanceId":"0"
            }
        ]
    },
    "dataserver": {
        "instances":[
            {
                "instanceId":"0"
            },
            {
                "instanceId":"1"
            }
        ]
    },
    "cacheserver": {
        "instances":[
            {
                "instanceId":"0"
            },
            {
                "instanceId":"1"
            }
        ]
    },
    "vizqlserver": {
        "instances":[
            {
```

```

        "instanceId":"0"
      },
      {
        "instanceId":"1"
      }
    ]
  },
  "backgrounder": {
    "instances":[
      {
        "instanceId":"0"
      },
      {
        "instanceId":"1"
      }
    ]
  },
  "appzookeeper": {
    "instances":[
      {
        "instanceId":"0"
      }
    ]
  },
  "pgsql": {
    "instances":[
      {
        "instanceId":"0"
      }
    ]
  },

```

```
"dataengine": {
  "instances":[
    {
      "instanceId":"0"
    }
  ]
},
"licenseservice": {
  "instances":[
    {
      "instanceId":"0"
    }
  ]
},
"searchserver": {
  "instances":[
    {
      "instanceId":"0"
    }
  ]
},
"clustercontroller": {
  "instances":[
    {
      "instanceId":"0"
    }
  ]
},
"tabsvc": {
  "instances":[
    {
```

```

        "instanceId":"0"
      }
    ]
  },
  "vizportal": {
    "instances":[
      {
        "instanceId":"0"
      }
    ]
  },
  "tabadminagent": {
    "instances":[
      {
        "instanceId":"0"
      }
    ]
  },
  "clientfileservice": {
    "instances":[
      {
        "instanceId":"0"
      }
    ]
  },
  "gateway": {
    "instances":[
      {
        "instanceId":"0"
      }
    ]
  }
}

```

```
        }
    }
}
}
```

Server registration file template example

```
{
  "first_name" : "Andrew",
  "last_name" : "Smith",
  "phone" : "311-555-2368",
  "email" : "andrew.smith@mycompany.com",
  "company" : "My Company",
  "industry" : "Finance",
  "company_employees" : "500",
  "department" : "Engineering",
  "title" : "Senior Manager",
  "city" : "Kirkland",
  "state" : "WA",
  "zip" : "98034",
  "country" : "United States",
  "opt_in" : "true",
  "eula" : "true"
}
```

Install Tableau Server in a Disconnected (Air-Gapped) Environment

You can install Tableau Server in a disconnected environment that has no outside network access of any kind. Such disconnected environments, commonly referred to as air-gapped, are used when high security is needed to prevent data breaches or to guard against hacking. Air-gapped environments have no internet access, no outside network access, no outside wireless access, etc. The only means of getting software and data into or out of an air-gapped environment is by using removable media such as USB sticks or writable optical CDs or DVDs.

Installing Tableau Server in an air-gapped environment is an advanced task for IT administrators who are familiar with the security considerations, best practices, and pitfalls of installing software in air-gapped environments.

The following Tableau Server features will be unavailable or will have reduced functionality in an air-gapped environment:

- **Maps** – Tableau Server uses externally hosted map data by default. Beginning with version 2020.4.0, you can configure Tableau Server to use offline maps. With earlier versions of Tableau, maps are unavailable in an air-gapped environment unless you also install a map server in your air-gapped environment. For more details, see [Displaying Maps in an Air-Gapped Environment](#).
- **Licensing** – Tableau Server needs to connect to the internet in order to activate product keys. However, you can [manually activate](#) the product keys.
- **External data** – Any data located outside your air-gapped environment is unavailable.

Prerequisites

In order to install Tableau Server in an air-gapped environment, you'll need the following:

- Trusted computer with limited access to the internet that you can use to download the installation packages and resources required by Tableau Server. A trusted computer has been scanned and cleared of any viruses and malware.
- Trusted removable media that you can use to transfer the downloaded software to your air-gapped environment. Trusted removable media is removable media that is new and previously unused and comes from a reputable or known source. Trusted removable media has been scanned and verified that it does not contain any viruses or malware.
- Air-gapped environment with computers and storage that meet the [requirements](#) for installing Tableau Server.

Installing Tableau Server on an Air-Gapped Computer Running Windows

The easiest way to install Tableau Server on a computer in an air-gapped environment is to do so before the computer is placed into the air-gapped environment. If that is not possible you'll need to download the required packages to a trusted computer outside the air gap and transfer them to the air-gapped computer:

1. On a trusted computer outside the air gap with internet access, download the Tableau Server installation package.
2. Transfer the package to your removable media.
3. On your air-gapped computer, insert the removable media containing the Tableau Server installation package, and then [run the installer](#).

Note: Server ATR is the default activation method for Tableau Server 2021.4 and later. As of Tableau Server 2023.1 and later, you can use Server ATR to install into an air-gapped environment.

4. After installation is complete, you can activate the Tableau Server product keys. For more information, see [Activating Tableau Server in an Air-Gapped Environment](#).

Activating Tableau Server in an Air-Gapped Environment

Because an air-gapped computer is not connected to the internet, you'll need to perform the Tableau Server activation process manually.

Offline activation overview

Offline activation of Tableau Server involves the following steps:

1. Generate an offline activation request file.
2. Copy the offline activation request file to a computer with internet access.
3. Upload the offline activation request file to the [Tableau activation website](#).
4. Download the resulting offline activation response file from the website. You'll use this file to activate Tableau Server

Offline activation file name changes

Beginning in Tableau Server version 2023.1, the Tableau licensing system supports two underlying licensing technologies. From an administrative perspective, the only configuration difference between the two systems is the file types that are generated and consumed for off-line activation. The licensing technology is determined during the initial installation of Tableau Server, and cannot be changed after install.

We refer to the legacy (and still supported) version of licensing technology as FlexNet. The latest version of the technology is referred to as Server ATR. For more information, see [Activate Tableau Server Using the Authorization-To-Run \(ATR\) Service](#). The following table describes the file naming nomenclature for each technology. The table also includes the generic reference.

Generic file name	Server ATR file names	FlexNet file names
Off-lineActivationRequest	Off-lineActivationRequestFile_YYYYMMdd.hhmmss.json	Tableau-OfflineActivationRequest.tlq
Off-lineActivationResponse	Off-lineActivationLicensingAtrs.zip	activation.tlf

Note: Since this documentation supports multiple versions of Tableau Server, we will use the generic file name references (OfflineActivationRequest and Off-lineActivationResponse) for the rest of this topic. You can identify the licensing technology your Tableau Server installation uses according to the file type that generated in the steps that follow.

Step 1. Log in to Tableau Services Manager

- To log in to Tableau Services Manager (TSM), run the following command:

```
tsm login -u <username>
```

What if I can't log in?

Verify that the account you are using is a member of the Local Administrators group on the Windows computer where you are installing Tableau Server.

Step 2. Determine your Tableau Server licensing type

How you activate Tableau Server will be different depending on which licensing type you are running. Run the following command to determine the licensing type your Tableau Server deployment is configured with:

```
tsm configuration get -k serverauthorizationtorun.enabled
```

If this command returns `true`, then your deployment is configured with Server ATR licensing type.

If this command returns `false`, then your deployment is configured with legacy licensing type.

Go to the step 3 that matches your licensing type.

Step 3 (Server ATR licensing type) Generate and copy json content to Activation page.

Follow these steps if your Tableau Server deployment is configured with Server ATR licensing type. If your server is configured with the legacy licensing type, skip to the following section.

1. On your Tableau Server in the air-gapped environment, use TSM to obtain the offline activation file. At a command prompt:

```
tsm licenses get-offline-activation-file -k <product-key> -o  
<target-directory>
```

The `<target-directory>` must exist. You can obtain your product key in the [Tableau Customer Portal](#).

2. Copy the JSON file contents.
3. From the internet connected computer, navigate to the [Tableau Offline Activation](#) website, select **Option B - Manually Enter Information from Activation File**, copy the JSON contents into the requested fields, and then click **Submit**.
4. The website should say `The activation was successful. Please click here to download your activation file.`

Download the `OfflineActivationResponse` file from Tableau, and proceed to step 4.

Step 3 (Legacy licensing type) Transcribe data from your air-gapped system into an activation request template.

Follow these steps if your Tableau Server deployment is configured with the legacy licensing type. If your server is configured with the Server ATR licensing type, run the above procedure.

1. On your Tableau Server in the air-gapped environment, use TSM to obtain the offline activation file. At a command prompt:

```
tsm licenses get-offline-activation-file -k <product-key> -o  
<target-directory>
```

The `<target-directory>` must exist. You can obtain your product key in the [Tableau Customer Portal](#).

2. If you can copy the offline request file (OfflineActivationRequest) from the target directory to a computer that has Internet access, skip to step 5.

Otherwise, if you cannot copy the file to another computer due to security reasons, continue with step 3.

3. Download and open the `server_windows.tlq` file in an XML text editor such as Notepad++ on a trusted computer that has Internet access.

You'll need to write down the values listed in step 4 from the air-gapped computer in order to copy them to the offline template (`server_windows.tlq`).

4. Update the following XML elements in the appropriate `server_windows.tlq` file with the values for the same elements listed below from the air-gapped computer.

All the Machine / Hash values in the `.tlq` files are Hex values. The only valid characters are 0 - 9 and A - F. Use all caps for any letters.

Do not add any additional spaces or carriage controls and only modify the "X" characters found in the template. The format of the file must not change.

Line 2 - <EntitlementId>

Line 5 - <ClientVersion>

Line 5 - <RevisionType> (This value is present in the server_windows.tlq file.)

Line 5 - <MachineIdentifier> (This value is present in the server_windows.tlq file.)

Line 11 - <Value> (If the value is not present, remove the "X" place holder, leaving <Value></Value>.)

Line 12 - <Value> (If the value is not present, remove the "X" place holder, leaving <Value></Value>.)

Line 14 - <SequenceNumber>

Line 60 - <Hash>

5. Upload the offline request file (OfflineActivationRequest) to the [Tableau Offline Activation](#) website.
6. The website should say The activation was successful. Please click here to download your activation file.

Download the OfflineActivationResponse file from Tableau.

Step 4. Initialize or activate your license

1. Move the OfflineActivationResponse file to your air-gapped computer using trusted removable media.
2. Run the following command:

```
tsm licenses activate -f <path-and-activation-file>
```

You should see the message "Activation successful.", which indicates that Tableau Server is activated.

Displaying Maps in an Air-Gapped Environment

In an air-gapped environment, maps in Tableau Server will be unavailable by default due to the lack of internet access. Instead, you can configure Tableau to use local maps in an air-gapped environment using the steps below.

Configuring Tableau Server to use offline maps:

1. Open a command prompt as administrator.
2. Configure Tableau to use locally available offline maps:

```
tsm configuration set -k vizqlserver.force_maps_to_offline -v true  
  
tsm pending-changes apply
```

Clone Tableau Server

Beginning with version 2022.3 of Tableau Server, a new tsm command enables you to create a copy of the configuration and topology of a Tableau Server deployment and use that to create an exact replica of the original deployment. The command, `tsm settings clone`, creates a set of files (the "clone payload") includes settings, secrets, configuration, and topology, including ports being used, and information about external services.

Security considerations

The `tsm settings clone` command generates a set of files (the "clone payload") that contain all the secrets generated by Tableau Server, as well as those provided by the server administrator during configuration, including a keystore containing keypairs and certificates. It is extremely important for security that you keep the clone payload and the output location secure. To facilitate this:

- If the output directory does not exist, tsm will create it with access restricted to the user running the `tsm settings clone` command.
- If the output directory exists when you run the command, tsm will confirm that it is owned by the user running the command, and that permissions are limited to only that user. If the directory does not have the expected permissions, a message displays:

```
The output directory '<path/to/directory>' exists, but must be
restricted to owner only.
```

Limitations of the clone payload

- The version of Tableau Server being cloned must match the version being created. You cannot install a newer version of Server using a clone payload from an older version.

Using the clone command to create a copy of Tableau Server

Creating a cloned copy of Tableau Server is a multi-step process, with the two high level steps being:

1. Create a clone payload from the Tableau Server installation you want to duplicate.
2. Use the clone payload to install a second deployment of Tableau Server. You are responsible for matching the topology of the two installations, adding additional nodes to match the original deployment.

Creating the clone payload

To generate a set of files (clone payload) that contain the configuration and topology settings for Tableau Server, use the `tsm settings clone` command. The command takes a single argument, the output directory where the set of files should be saved:

```
tsm settings clone --output-directory <output_directory>
```

Once the clone payload is created, you can use this when installing a new instance of Tableau Server with the identical configuration and topology of the source installation.

Using the clone payload to create a copy of Tableau Server

When installing Tableau Server on Windows, server administrator should take following steps:

1. Set the `CLONE_ARTIFACT_DIR` environment variable to point to the clone payload location.
2. Run the Tableau Server Setup program as Administrator.

Do not initialize Tableau Server if your topology includes additional nodes. You need to add those nodes before completing the process of initializing Tableau Server.

3. Optional: Add worker nodes

After TSM is initialized (but before initializing Tableau Server) the administrator should add additional nodes if original topology had more than 1 node.

This should be done following the standard process for adding new nodes, i.e. generate a bootstrap file and run `initialize-tsm` script on worker nodes providing the bootstrap file.

For details, see [Install and Configure Additional Nodes](#).

4. Initialize Tableau Server using TSM web interface or command line interface:

```
tsm initialize
```

5. Wait for Tableau Server to initialize on all nodes.

Post Installation Tasks

After you install Tableau Server, you can perform other configuration tasks, such as reviewing the security hardening checklist, configuring server event notifications, configuring the data cache for views, and configuring server crash reporting.

Security Hardening Checklist

The following list provides recommendations for improving the security ("hardening") of your Tableau Server installation.

Looking for Tableau Server on Linux? See [Security Hardening Checklist](#)

Installing security updates

Security updates are included in the latest versions and maintenance releases (MR) of Tableau Server. You cannot install security updates as patches. Rather, you must upgrade to a current version or MR to update Tableau Server with the latest security fixes.

Always reference the most current version of this topic after upgrading. The current version includes `/current/` in the topic URL.

For example, the US version URL is: https://help.tableau.com/current/server/en-us/security_harden.htm.

1. Update to the current version

We recommend that you always run the latest version of Tableau Server. Additionally, Tableau periodically publishes maintenance releases of Tableau Server that include fixes for known security vulnerabilities. (Information regarding known security vulnerabilities can be found on the Tableau [Security Bulletins](#) page and the [Salesforce Security Advisories](#) page.) We recommend that you review maintenance release notifications to determine whether you should install them.

To get the latest version or maintenance release of Tableau Server, visit the [Customer Portal](#) page.

2. Configure SSL/TLS with a valid, trusted certificate

Secure Sockets Layer (SSL/TLS) is essential for helping to protect the security of communications with Tableau Server. Configure Tableau Server with a valid, trusted certificate (not a self-signed certificate) so that Tableau Desktop, mobile devices, and web clients can connect to the server over a secured connection. For more information, see [SSL](#).

3. Disable older versions of TLS

Tableau Server uses TLS to authenticate and encrypt many connections between components and with external clients. External clients, such as browsers, Tableau Desktop, Tableau Mobile connect to Tableau using TLS over HTTPS. Transport layer security (TLS) is an improved version of SSL. In fact, older versions of SSL (SSL v2 and SSL v3) are no longer considered to be adequately secure communication standards. As a result, Tableau Server does not allow external clients to use SSL v2 or SSL v3 protocols to connect.

We recommend that you allow external clients to connect to Tableau Server with TLS v1.3 and TLS v1.2.

TLS v1.2 is still regarded as a secure protocol and many clients (including Tableau Desktop) do not yet support TLS v1.3.

TLS v1.3 capable clients will negotiate TLS v1.3 even if TLS v1.2 is supported by the server.

The following tsm command enables TLS v1.2 and v1.3 (using the "all" parameter) and disables SSL v2, SSL v3, TLS v1, and TLS v1.1 (by prepending the minus [-] character to a given protocol). TLS v1.3 is not yet supported by all components of Tableau Server.

```
tsm configuration set -k ssl.protocols -v "all -SSLv2 -SSLv3 -TLSv1  
-TLSv1.1"
```

```
tsm pending-changes apply
```

To modify the protocols that govern SSL for the Tableau Server PostgreSQL repository, see [pgsql.ssl.ciphersuite](#).

You can also modify the default list of cipher suites that Tableau Server uses for SSL/TLS sessions. For more information see the *ssl.ciphersuite* section at tsm configuration set Options.

4. Configure SSL encryption for internal traffic

Configure Tableau Server to use SSL to encrypt all traffic between the Postgres repository and other server components. By default, SSL is disabled for communications between server components and the repository. We recommend enabling internal SSL for all instances of Tableau Server, even single-server installations. Enabling internal SSL is especially important for multi-node deployments. See [Configure SSL for Internal Postgres Communication](#).

5. Enable firewall protection

Tableau Server was designed to operate inside a protected internal network.

Important: Do not run Tableau Server, or any components of Tableau Server on the internet or in a DMZ. Tableau Server must be run within the corporate network protected by an internet firewall. We recommend configuring a reverse proxy solution for internet clients that need to connect to Tableau Server. See [Configuring Proxies and Load Balancers for Tableau Server](#).

A local firewall should be enabled on the operating system to protect Tableau Server in single and multi-node deployments. In a distributed (multi-node) installation of Tableau Server, communication between nodes does not use secure communication. Therefore, you should enable firewalls on the computers that host Tableau Server.

To prevent a passive attacker from observing communications between nodes, configure a segregated virtual LAN or other network layer security solution.

See [Tableau Services Manager Ports](#) to understand which ports and services Tableau Server requires.

6. Restrict access to the server computer and to important directories

Tableau Server configuration files and log files can contain information that is valuable to an attacker. Therefore, restrict physical access to the machine that is running Tableau Server. In addition, make sure that only authorized and trusted users have access to the Tableau Server files in the `C:\ProgramData\Tableauidirectory`.

7. Update the Tableau Server Run As User account

By default, Tableau Server runs under the predefined Network Services (NT Authority\Network Service) Windows account. Using the default account is acceptable in scenarios where Tableau Server does not need to connect to external data sources that require Windows authentication. However, if your users require access to data sources that are authenticated by Active Directory, update the Run As User to a domain account. It's important to minimize the rights of the account that you use for the Run As User. For more information, see [Run As Service Account](#).

8. Generate fresh secrets and tokens

Any Tableau Server service that communicates with repository or the cache server must first authenticate with a secret token. The secret token is generated during Tableau Server setup. The encryption key that internal SSL uses to encrypt traffic to Postgres repository is also generated at during setup.

We recommend that after you install Tableau Server, you generate new encryption keys for your deployment.

These security assets can be regenerated with the `tsm security regenerate-internal-tokens` command.

Run the following commands:

```
tsm security regenerate-internal-tokens
```

```
tsm pending-changes apply
```

9. Disable services that you're not using

To minimize the attack surface of the Tableau Server, disable any connection points that are not needed.

JMX Service

JMX is disabled by default. If it's enabled but you're not using it, you should disable it by using the following:

```
tsm configuration set -k service.jmx_enabled -v false  
  
tsm pending-changes apply
```

10. Verify session lifetime configuration

By default, Tableau Server does not have an absolute session timeout. This means that browser-based client (Web authoring) sessions can remain open indefinitely if the Tableau Server inactivity timeout is not exceeded. The default inactivity timeout is 240 minutes.

If your security policy requires it, you can set an absolute session timeout. Be sure to set your absolute session timeout in a range that allows the longest-running extract uploads or work-book publishing operations in your organization. Setting the session timeout too low may result in extract and publishing failures for long-running operations.

To set the session timeout run the following commands:

```
tsm configuration set -k wgserver.session.apply_lifetime_limit -v  
true  
  
tsm configuration set -k wgserver.session.lifetime_limit -v value,  
where value is the number of minutes. The default is 1440, which is 24 hours.  
  
tsm configuration set -k wgserver.session.idle_limit -v value, where  
value is the number of minutes. The default is 240.  
  
tsm pending-changes apply
```

Sessions for connected clients (Tableau Desktop, Tableau Mobile, Tableau Prep Builder, Bridge, and personal access tokens) use OAuth tokens to keep users logged in by re-establishing a session. You can disable this behavior if you want all Tableau client sessions to be solely governed by the browser-based session limits controlled by the commands above. See [Disable Automatic Client Authentication](#).

11. Configure a server allowlist for file-based data sources

As of October 2023 Tableau Server releases, default file-based access behavior has changed. Previously, Tableau Server allowed authorized Tableau Server users to build workbooks that use files on the server as file-based data sources (such as spreadsheets). With the October 2023 releases, access to files stored on Tableau or on remote shares must be specifically configured on Tableau Server using the setting described here.

This setting allows you to limit access by the Run As Service Account only to those directories that you specify.

To configure access to shared files, you must configure allowlist functionality. This lets you limit the Run As service account to just the local directory paths, or shared directories where you host data files.

1. On the computer running Tableau Server, identify the directories where you will host data source files.

Important Make sure the file paths you specify in this setting exist and are accessible by the service account. If the paths are not accessible when the computer starts, Tableau Server will not start.

2. Run the following commands:

```
tsm configuration set -k native_api.allowed_paths -v "path",  
where path is the directory to add to the allowlist. All subdirectories of the specified path
```

will be added to the allowlist. If you want to specify multiple paths, separate them with a semicolon, as in this example:

```
tsm configuration set -k native_api.allowed_paths -v "c:\data-
sources;\\HR\data"

tsm pending-changes apply
```

12. Enable HTTP Strict Transport Security for web browser clients

HTTP Strict Transport Security (HSTS) is a policy configured on web application services, such as Tableau Server. When a conforming browser encounters a web application running HSTS, then all communications with the service must be over a secured (HTTPS) connection. HSTS is supported by major browsers.

For more information about how HSTS works and the browsers that support it, see The Open Web Application Security Project web page, [HTTP Strict Transport Security Cheat Sheet](#).

To enable HSTS, run the following commands on Tableau Server:

```
tsm configuration set -k gateway.http.hsts -v true
```

By default, HSTS policy is set for one year (31536000 seconds). This time period specifies the amount of time in which the browser will access the server over HTTPS. You should consider setting a short max-age during initial roll-out of HSTS. To change this time period, run `tsm configuration set -k gateway.http.hsts_options -v max-age=<seconds>`. For example, to set HSTS policy time period to 30 days, enter `tsm configuration set -k gateway.http.hsts_options -v max-age=2592000`.

```
tsm pending-changes apply
```

13. Disable Guest access

Core-based licenses of Tableau Server include a Guest user option, which allows any user in your organization to see and interact with Tableau views embedded in web pages.

Guest user access is enabled by default on Tableau Servers deployed with core-based licensing.

Guest access allows users to see embedded views. The Guest user cannot browse the Tableau Server interface or see server interface elements in the view, such as user name, account settings, comments, and so on.

If your organization has deployed Tableau Server with core licensing and Guest access is not required, then disable Guest access.

You can disable Guest access at the server or site level.

You must be a server administrator to disable the Guest account at either the server or the site level.

To disable Guest access at the server level:

1. In the site menu, click **Manage All Sites** and then click **Settings > General**.
2. For **Guest Access**, clear the **Enable Guest account** check box.
3. Click **Save**.

To disable Guest access for a site:

1. In the site menu, select a site.
2. Click **Settings**, and on the Settings page, clear the **Enable Guest account** check box.

For more information, see Guest User.

14. Set referrer-policy HTTP header to 'same-origin'

Beginning in 2019.2, Tableau Server includes the ability to configure Referrer-Policy HTTP header behavior. This policy is enabled with a default behavior that will include the origin URL for all "secure as" connections (`no-referrer-when-downgrade`), which sends origin refer-

rer information only to like connections (HTTP to HTTP) or those that are more secure (HTTP to HTTPS).

However, we recommend setting this value to `same-origin`, which only sends referrer information to same-site origins. Requests from outside the site will not receive referrer information.

To update the `referrer-policy` to `same-origin`, run the following commands:

```
tsm configuration set -k gateway.http.referrer_policy -v same-origin  
  
tsm pending-changes apply
```

For more information about configuring additional headers to improve security, see HTTP Response Headers.

15. Configure TLS for SMTP connection

Beginning in 2019.4, Tableau Server includes the ability to configure TLS for the SMTP connection. Tableau Server only supports STARTTLS (Opportunistic or Explicit TLS).

Tableau Server can be optionally configured to connect to a mail server. After configuring SMTP, Tableau Server can be configured to email server administrators about system failures, and email server users about subscribed views and data-driven alerts.

To configure TLS for SMTP:

1. Upload a compatible certificate to Tableau Server. See `tsm security custom-cert add`.
2. Configure TLS connection using TSM CLI.

Run the following TSM commands to enable and force TLS connections to the SMTP server and to enable certificate verification.

```
tsm configuration set -k svcmonitor.notification.smtp.ssl_enabled -v true
```

Tableau Server on Windows Help

```
tsm configuration set -k svcmonitor.notification.smtp.ssl_  
required -v true
```

```
tsm configuration set -k svcmonitor.notification.smtp.ssl_  
check_server_identity -v true
```

By default, Tableau Server will support TLS versions 1, 1.1, and 1.2, but we recommend that you specify the highest TLS version that the SMTP server supports.

Run the following command to set the version. Valid values are `SSLv2Hello`, `SSLv3`, `TLSv1`, `TLSv1.1`, and `TLSv1.2`. The following example sets the TLS version to version 1.2.:

```
tsm configuration set -k svcmonitor.notification.smtp.ssl_ver-  
sions -v "TLSv1.2"
```

For more information about other TLS configuration options, see [Configure SMTP Setup](#).

3. Restart Tableau Server to apply changes. Run the following command:

```
tsm pending-changes apply
```

16. Configure SSL for LDAP

If your Tableau Server deployment is configured to use a generic LDAP external identity store, we recommend configuring SSL to protect authentication between Tableau Server and your LDAP server. See [Configure Encrypted Channel to LDAP External Identity Store](#).

If your Tableau Server deployment is configured to use Active Directory, we recommend enabling Kerberos to protect authentication traffic. See [Kerberos](#).

17. Scope permissions for non-default installation locations

If you install Tableau Server on Windows to a non-default location then we recommend manually scoping the permissions on the custom installation directory to reduce access.

By default, Tableau Server will install on the system drive. The drive where Windows is installed is the system drive. In most cases, the system drive is the C:\ drive. In this default case, Tableau Server will install into the following directories:

- C:\Program Files\Tableau\Tableau Server\packages
- C:\ProgramData\Tableau\Tableau Server

However, many customers install onto a non-system drive or into a different directory. If you selected a different installation drive or directory location during Setup, then the data directory for Tableau Server will install into the same path.

To scope permissions on the custom installation directory, only the following accounts should have the corresponding permissions on the installation folder and all subfolders:

Set permissions for this account:	Permissions required
The user account that is used to install and upgrade Tableau Server	Full control
The user account that is used to run TSM commands	Full control
System account	Full control
Run As service account, Network Service, and Local Service	Read & execute

A procedure for setting these permissions can be found at [Installing in a non-default location](#).

Change List

Date	Change
May 2018	Added clarification: Do not disable REST API in organizations that are running Tableau Prep.

May 2019	Added recommendation for referrer-policy HTTP header.
June 2019	Removed recommendation to disable Triple-DES. As of version 2019.3, Triple-DES is no longer a default supported cipher for SSL. See What's Changed - Things to Know Before You Upgrade.
January 2020	Added recommendation to configure TLS for SMTP.
February 2020	Added recommendation to configure SSL for LDAP server.
May 2020	Added TLS v1.3 to the disabled list of TLS ciphers. Added clarification to introduction about topic versioning.
August 2020	Added scoped permissions for non-default installations on Windows
October 2020	Added TLS v1.3 as a default supported cipher.
January 2021	Added clarification: All products enabled by the Data Management license require REST API.
February 2021	Removed recommendation to disable REST API. The API is now used internally by Tableau Server and disabling it may limit functionality.

Configure SMTP Setup

Tableau Server can email server administrators about system failures, and email server users about subscribed views and data-driven alerts. First, however, you need to configure the SMTP server that Tableau Server uses to send email. After configuring SMTP, complete the steps to configure notifications (Configure Server Event Notification), then when you start or restart the server, it will trigger an email notification, which confirms that you have set up notifications correctly.

Configuring SMTP requires that you restart Tableau Server services.

Secure SMTP

To enable and configure TLS for SMTP, you must use the TSM CLI as described in this topic. Tableau Server only supports STARTTLS (Opportunistic or Explicit TLS).

If your organization does not use public certificates for verifying TLS connections, then you can upload a private certificate to Tableau Server to verify trusted connections. For more information, see the `tsm security custom-cert add` command.

You may also configure SMTP TLS for encryption-only by disabling the certificate validation process. For more information, see the section, *Configuration file reference*, in the *Use the TSM CLI* tab below.

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see Sign in to Tableau Services Manager Web UI.

2. Click **Notifications** on the **Configuration** tab and click **Email Server**.
3. Enter the SMTP configuration information for your organization:

Tableau Server on Windows Help

The screenshot shows the 'CONFIGURATION' tab in the Tableau Server interface. Under the 'Notifications' section, the 'Email Server' sub-tab is active. The 'Configure email server' section contains several input fields: 'SMTP server address' (smtp.example.lan), 'Username' (tableau-notify@example.lan), 'Password' (masked with dots), 'Port Number' (25 (Default)), 'Send all emails from' (no-reply@example.lan), 'Send server health email to' (tableau-health@example.lan), and 'Tableau Server URL' (https://tableau.example.lan). There are also buttons for 'Cancel' and 'Save Pending Changes'.

4. Click **Save Pending Changes** after you've entered your configuration information.
5. Click **Pending Changes** at the top of the page:

6. Click **Apply Changes and Restart**.
7. Run the `tsm email test-smtp-connection` to view and verify the connection configuration. See `tsm email test-smtp-connection`.

Use the TSM CLI

For the initial configuration of SMTP, we recommend that you use the configuration file template below to create a json file. You can also set any single configuration key listed below with the syntax described in `tsm configuration set`.

1. Copy the following json template to a file.

Important: The template below includes common options for most deployments. After you copy the template to a text file, you must edit the option values for your SMTP server requirements. You may need to remove or add options. See the reference section that follows for more information about all supported SMTP key options.

```
{
  "configKeys": {
    "svcmonitor.notification.smtp.server": "SMTP server host
name",
    "svcmonitor.notification.smtp.send_account": "SMTP user name",
    "svcmonitor.notification.smtp.port": 443,
    "svcmonitor.notification.smtp.password": "SMTP user account
password",
    "svcmonitor.notification.smtp.ssl_enabled": true,
    "svcmonitor.notification.smtp.from_address": "From email
address",
    "svcmonitor.notification.smtp.target_addresses": "To email
address1,address2",
    "svcmonitor.notification.smtp.canonical_url": "Tableau Server
URL"
  }
}
```

2. Run the `tsm settings import -f file.json` to pass the json file with the appropriate values to Tableau Services Manager to configure Tableau Server for SMTP. Tableau Services Manager will validate the entity values.
3. Run the `tsm pending-changes apply` command to apply the changes. See `tsm pending-changes apply`.

4. Run the `tsm email test-smtp-connection` to view and verify the connection configuration. See `tsm email test-smtp-connection`.

SMTP CLI configuration reference

This table lists all of the options that can be used to configure SMTP with TSM CLI.

Option	Description
<code>svc-monitor.notification.smtp.server</code>	Address of SMTP server. Example: "svc-monitor.notification.smtp.server": "mail.example.com"
<code>svc-monitor.notification.smtp.send_account</code>	User name for SMTP account.
<code>svc-monitor.notification.smtp.port</code>	Port number for SMTP server. The default is 25.
<code>svc-monitor.notification.smtp.password</code>	Password for SMTP server account. Example: "svc-monitor.notification.smtp.password": "password"
<code>svc-monitor</code>	Specifies whether the connection to the SMTP server is encrypted. The default is false.

Option	Description
<code>itor.notification.smtp.ssl_enabled</code>	
<code>svc-monitor.notification.smtp.ssl_required</code>	<p>If enabled, Tableau Server will refuse to connect to SMTP servers without using TLS. The <code>svc-monitor.notification.smtp.ssl_enabled</code> option must also be set to true.</p> <p>The default is false.</p>
<code>svc-monitor.notification.smtp.ssl_check_server_identity</code>	<p>If set to true, Tableau Server will check the SMTP server identity as specified by RFC 2595. These additional checks based on the content of the server's certificate are intended to prevent man-in-the-middle attacks.</p> <p>The default is false.</p>
<code>svc-monitor.notification.smtp.ssl_trust_all_hosts</code>	<p>When using TLS, trust certificates from all mail servers, ignoring the validity of the certificate's chain of trust. By setting this key to true, TLS will be used only to encrypt the traffic to the SMTP host.</p> <p>The default is false.</p>
<code>svc-monitor.notification.smtp.ssl_ciphers</code>	<p>The default and supported sets of cipher suites is defined by the version of JDK that is installed with Tableau Server. See the section below, TLS ciphers, for a list of supported and default ciphers.</p> <p>To update the cipher suites used by Tableau Server for SMTP TLS connections, enter a white</p>

Option	Description
	<p>space-separated list of cipher suites for this value. For example, "TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA256 TLS_DHE_DSS_WITH_AES_128_GCM_SHA256 TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384".</p>
<pre>svc- mon- itor.notification.smtp.ssl_ versions</pre>	<p>The default TLS versions enabled on this version of Tableau Server are TLSv1, TLSv1.1, TLSv1.2 and TLSv1.3.</p> <p>TLS version support is defined by the version of JDK that is installed with Tableau Server.</p> <p>Supported versions of TLS are SSLv2Hello, SSLv3, TLSv1, TLSv1.1, TLSv1.2, TLSv1.3.</p> <p>To update the versions used by Tableau Server for SMTP TLS connections, enter a white space-separated list of versions for this value. For example, "TLSv1.2 TLSv1.3".</p>
<pre>svc- mon- itor.notification.smtp.from_ address</pre>	<p>Email address that will send an notification if there's a system failure. The email address must have valid syntax (for example, ITalerts@bigco.-com or noreply@mycompany), but it does not have to be an actual email account on Tableau Server. (Some SMTP servers may require an actual email account, however.)</p> <div data-bbox="760 1591 1360 1684"> <p>Note: You can override the system-wide</p> </div>

Option	Description
	<p>email address on a per-site basis. For more information, see What is a site.</p> <p>Example:</p> <pre>"svcmonitor.notification.smtp.from_address": "donot-reply@example.com"</pre>
<pre>svc- mon- itor.no- tification.smtp.target_ addresses</pre>	<p>Email address to receive notifications. If email notifications are enabled, you need to include at least one address. Separate multiple addresses with commas.</p> <p>Example:</p> <pre>"svc- monitor.notification.smtp.target_ addresses": "iluvdata@example.com"</pre>
<pre>svc- mon- itor.no- tification.smtp.canonical_ url</pre>	<p>URL of the Tableau Server. Enter <code>http://</code> or <code>https://</code>, followed by the name or IP address of the Tableau server. Used in the footer of subscription email.</p> <p>Example:</p> <pre>"svc- monitor.notification.smtp.canonical_ url": "http://myserver.example.com"</pre>

TLS ciphers

The following is a list of TLS ciphers that are supported by the JDK that is included with Tableau Server. In this version of Tableau Server, all of these ciphers are enabled by default.

You can specify a custom list of ciphers for your SMTP configuration by entering a white-space separated list with the option, `svcmonitor.notification.smtp.ssl_ciphers`, as described in the table above.

TLS_RSA_WITH_AES_128_CBC_SHA256	TLS_ECDH_RSA_WITH_AES_256_GCM_SHA384
TLS_DHE_DSS_WITH_AES_256_GCM_SHA384	TLS_ECDH_RSA_WITH_AES_128_GCM_SHA256
TLS_ECDH_RSA_WITH_AES_256_CBC_SHA384	TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA
TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA	TLS_RSA_WITH_AES_256_CBC_SHA256
TLS_RSA_WITH_AES_128_GCM_SHA256	TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384
TLS_ECDH_RSA_WITH_AES_128_CBC_SHA256	TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
TLS_DHE_DSS_WITH_AES_128_CBC_SHA256	TLS_DHE_DSS_WITH_AES_256_CBC_SHA
TLS_DHE_RSA_WITH_AES_128_CBC_SHA256	TLS_DHE_RSA_WITH_AES_256_CBC_SHA256
TLS_RSA_WITH_AES_256_GCM_SHA384	TLS_EMPTY_RENEGOTIATION_INFO_SCSV
TLS_ECDH_ECDSA_WITH_AES_256_CBC_SHA384	TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	TLS_DHE_DSS_WITH_AES_256_CBC_SHA256

TLS_RSA_WITH_AES_256_CBC_SHA	TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA256	TLS_DHE_RSA_WITH_AES_256_CBC_SHA
TLS_DHE_DSS_WITH_AES_128_GCM_SHA256	TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	TLS_ECDH_RSA_WITH_AES_128_CBC_SHA
TLS_DHE_RSA_WITH_AES_256_GCM_SHA384	TLS_DHE_RSA_WITH_AES_128_CBC_SHA
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA
TLS_DHE_RSA_WITH_AES_128_GCM_SHA256	TLS_ECDH_ECDSA_WITH_AES_128_GCM_SHA256
TLS_ECDH_RSA_WITH_AES_256_CBC_SHA	TLS_DHE_DSS_WITH_AES_128_CBC_SHA
TLS_ECDH_ECDSA_WITH_AES_256_CBC_SHA	TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
TLS_RSA_WITH_AES_128_CBC_SHA	TLS_ECDH_ECDSA_WITH_AES_256_GCM_SHA384
TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384	TLS_AES_256_GCM_SHA384
TLS_AES_128_GCM_SHA256	

Configure Server Event Notification

A Tableau Services Manager (TSM) administrator can configure Tableau Server to allow notifications for the following events:

- Content updates
 - Extract failures (enabled by default)
 - Subscription views for users (disabled by default)
- Server health monitoring
 - Server status changes (disabled by default)
 - Desktop License reporting (disabled by default)
- Drive space
 - Email alerts when disk space crosses or remains below pre-configured thresholds (disabled by default)
 - Recording usage history (enabled by default)

Note: You need to configure SMTP before you can configure subscriptions or notifications. For more information, see [Configure SMTP Setup](#).

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850.`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click **Notifications** on the **Configuration** tab and click **Events**.
3. Configure notification settings for your organization:
 - Content updates

- **Send emails for extract refresh failures**

When this option is enabled (the default), a server administrator can configure email notifications to be sent when extract refreshes fail. These

messages are configured at the site level, so even if this option is enabled, messages are not sent unless the **Send email to data source and workbook owners when scheduled refreshes fail** option is enabled for a site (this is enabled by default). For details, see [Enable Extract Refresh Scheduling and Failure Notification](#).

- **Allow users to receive email for views that they have subscribed to**

When this option is enabled (by default is it disabled), a server administrator can configure a site to send subscription email. These email messages are configured at the site level and can only be configured when this option is enabled. For details, see [Set Up a Site for Subscriptions](#).

When users subscribe to a workbook or view, a snapshot of the view is emailed to them on a scheduled basis, so they can see the latest updates without having to sign into Tableau Server.

To allow users to attach PDF renderings on subscription emails, select **Let users add attachments to subscribed views**.

- Server health monitoring

- **Send emails for Tableau Server process events (up, down, and fail-over)**

Tableau Server sends an email message when the data engine, file store, gateway, or repository server processes stop or restart, or when the initial Tableau Server node stops or restarts.

If you are running a single-server installation (all processes on the same computer), health alerts are only sent when Tableau Server is up. No "down" alerts are sent. If you are running a distributed installation that's configured for failover, a DOWN alert means that the active repository or a data engine instance has failed and the subsequent UP alert means that

the passive instance (repository) or second instance (data engine) of that process has taken over.

Note: Tableau Server is designed to be self-correcting. If a service or process stops responding or goes down, Tableau Server attempts to restart it. This can take 15 to 30 minutes to complete. Because of this, reacting immediately to service or process alerts can be counter-productive, especially in an installation with redundant services that can handle requests while one restarts.

- **Enable Tableau Desktop License reporting**

License reporting data originates in Tableau Desktop and is sent to Tableau Server. When this option is enabled, Tableau Server will generate and display the administrative report for Desktop License reporting. For information on the report, see Desktop License Usage.

- **Drive space**

Enable notifications (alerts) for remaining disk space on your Tableau Server.

- **Send emails when unused drive space drops below thresholds**

You can configure Tableau Server to send email notifications when disk space usage on any node crosses a threshold, or remains below the threshold. And you can configure how often threshold notifications are sent.

There are two thresholds you must set, **Warning threshold** and **Critical threshold**. Thresholds are expressed in percentage of disk

space remaining. The critical threshold must be less than the warning threshold.

You also specify the **Send threshold alert every** option. This determines how often, in minutes, warning and critical notifications should be sent. The default value is 60 minutes.

- **Record disk space usage information and threshold violations for use in custom administrative views**

When you configure Tableau Server to record disk space usage, information about free disk space is saved in the repository and you can view the usage history using the Administrative Views.

4. Click **Save Pending Changes** after you've entered your configuration information.
5. Click **Pending Changes** at the top of the page:

6. Click **Apply Changes and Restart**.

Use the TSM CLI

The various notification values described above can be set individually with the `tsm configuration set` command. Alternatively, you can construct a json file and pass all configuration values in one operation. Both methods are described in this section.

Set notification values individually

The following table shows the key/value pairs that map to the notification events described earlier in this topic. Use the `tsm configuration set` command with the following syntax to set a single key/value pair:

```
tsm configuration set -k <config.key> -v <config_value>
```

For example, to enable job failure notifications, run the following command:

```
tsm configuration set -k backgrounder.notifications_enabled -v true
```

Notification option	Key	Value
Extract failures or Flow run failures	backgrounder.notifications_enabled	true false
Enable subscription views for user	subscriptions.enabled	true false
Enable PDF attachments for subscriptions	subscriptions.attachments_enabled	true false
Maximum attachment size (MB) for subscription notifications	subscriptions.max_attachment_size_megabytes	integer value, default is 150
Server status changes	svcmonitor.notification.smtp.enabled	true false
License reporting	features.DesktopReporting	true false
Remaining space thresholds: enable email notifications	storage.monitoring.email_enabled	true false
Remaining space thresholds: warn-	storage.monitoring.warning_percent	integer value, for example, 20

ing percentage		
Remaining space thresholds: critical percentage	<code>storage.monitoring.critical_percent</code>	integer value, for example, 15
Set email interval	<code>storage.monitoring.email_interval_min</code>	integer value, in minutes, for example, 25
Record usage history	<code>storage.monitoring.record_history_enabled</code>	true false

After you are done setting values, you must run the following command:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Set all notification values with a single json file

To make all notifications settings with a single configuration, you can pass a json file.

Copy and edit the following template to create a file for your configuration.

```
{
  "configKeys": {
    "backgrounder.notifications_enabled": true,
    "subscriptions.enabled": true,
    "subscriptions.attachments_enabled": true,
    "subscriptions.max_attachment_size_megabytes": 150,
    "svcmonitor.notification.smtp.enabled": true,
```

Tableau Server on Windows Help

```
"features.DesktopReporting": true,  
"storage.monitoring.email_enabled": true,  
"storage.monitoring.warning_percent": 20,  
"storage.monitoring.critical_percent": 15,  
"storage.monitoring.email_interval_min": 25,  
"storage.monitoring.record_history_enabled": true  
}  
}
```

After you have saved the file, pass it with the following command:

```
tsm settings import -f <path-to-file.json>
```

To apply changes, run the following command:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Configure Data Cache

Views published to Tableau Server are interactive and sometimes have a live connection to a database. As users interact with the views in a web browser, the data that is queried gets stored in a cache. Subsequent visits will pull the data from this cache if it is available. By default, Tableau Server will cache and reuse data for as long as possible. You can change this behavior by configuring the caching option using the `tsm data-access caching set` command.

1. Run this command:

```
tsm data-access caching set -r <value>
```

Where <value> is one of these options:

- **low or empty string ("").** This is the default value and indicates that Tableau Server should configure cache and always use cached data when available.
 - **<value>.** "<value>" specifies the maximum number of minutes data should be cached.
 - **always or 0 (zero).** These values indicates that Tableau Server should always get the latest data and that the cache should be refreshed each time a page is reloaded.
2. Apply changes with the `tsm pending-changes apply` command. This will restart Tableau Server.

Database Drivers

Tableau connectors require a driver to talk to the database. Before you can connect to data sources from Tableau Server, you must install drivers for the data sources you want to connect to. You can find driver links and installation instructions for all the supported connectors on the [Driver Download page](#).

Important: Beginning with version 2023.1.0 you must install the PostgreSQL driver if you want to use the built-in administrative views. You can find this on the [Driver Download page](#).

Install drivers in a cluster

You need to install the drivers for your data sources on the initial node in a Tableau Server cluster. If you install Tableau Server on multiple nodes, you must also install drivers on any node that runs any of the following processes:

- Application Server (Vizportal)
- Backgrounder
- Data Server
- VizQL Server

Tableau Server Pre-Flight Check

Introduced in version 2020.3.0 of Tableau Server on Windows, the pre-flight check (PFC) does basic checks of key system configurations to help avoid common installation and upgrade problems.

- **Install**—During installation of Tableau Server on Windows, a check of permissions on the installation directory and the data directory are done. If this check determines that permissions aren't adequate for Tableau Server to run successfully, the installation will not fail, but any errors are logged to the Administration Controller log.
- **Upgrade**—During upgrade of Tableau Server on Windows, when you run the `upgrade-tsm.cmd` script, checks of permissions on the installation and data directories are done, along with verification that the ports necessary for specific services are available. Any permissions issues are logged to the `app-upgrade.log` but do not block the upgrade. Port conflicts stop the upgrade process before initialization starts, allowing you to correct the problem. Because this happens *before* initialization of the new version, you can continue to use your existing version while you investigate the issue, then rerun the `upgrade-tsm` script.

tsm pre-flight check commands

Two tsm commands gives you the ability to check permissions and ports before running an upgrade, and fix any issues:

```
tsm maintenance preflight-check permissions
```

```
tsm maintenance preflight-check ports
```

Server Crash Reporter

The Tableau Server administrator can enable an option to allow logs and related files to be sent to Tableau when the server has an issue that results in a crash. These files are used by Tableau to identify and address issues that cause crashes. By default this option is disabled, and it should only be enabled in organizations that are not subject to regulations related to data privacy.

Important: Do not enable crash reporting if your data is subject to privacy regulations.

If Tableau Server has a problem that results in a crash, log files and dump files are generated. If the crash data upload feature is enabled, these files are automatically gathered and zipped into an encrypted package that is sent in the background, at the scheduled time. The encrypted package is sent in small pieces to limit impact to network performance. Only one crash report is packaged and uploaded at a time (a new crash report is not packaged until the previous package has been uploaded) and is sent in a "first in, first out" order. You can schedule the sending for a low-use window to further reduce any impact to your users.

The encrypted package is made up crash dump files and logs that include the following:

- Crash/core dump files
- Error log files related to the crash
- Manifest files related to the crash

The files can contain data that includes:

- Machine-specific information (for example: hardware, operating system, domain).
- A snapshot of the contents of memory at the time of the crash, including application activity details like information about data connections, actions taken by the user in Tableau, and data being worked on in Tableau.
- Tableau information including customer-identifiable information.

Configure Server Crash Reporter

Server crash reporting is disabled by default. This topic describes how to enable and configure server crash reporting. Crash reports are encrypted and sent to Tableau. See Server Crash Reporter for more information.

If your organization uses a proxy server to connect to the internet then you must configure server crash reporter to use the proxy. Even if you have already configured Tableau Server to use a proxy, you must also configure server crash reporter separately. To configure proxy for server crash reporter you must use TSM CLI procedure as described in this topic.

Important: Do not enable crash reporting if your data is subject to privacy regulations.

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the **Maintenance** tab.
3. Under Other Maintenance Tasks, in Server Crash Reporter, select **Enable crash reporting**:

Server Crash Reporter

Send logs and related files to Tableau when the server has an issue that results in a crash. Do not enable this feature if your organization's data is subject to any privacy regulations.

[Learn more](#)

☐ Enable crash reporting Daily at ▼

4. Specify the scheduled time of day to upload the crash reports to Tableau.
5. When you are finished, click **Pending Changes**, and then click **Apply Changes and Restart**.

Use the TSM CLI

Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```
tsm settings import -f path-to-file.json
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Tableau Server on Windows Help

Because the configuration file is using configKey class, the values that you pass are not validated by TSM as they are when you use configEntities class. You can verify and set individual options by using the tsm configuration commands.

Crash reporter settings

The crash reporter settings in the template below specify a range of options for configuring Tableau Server to send crash reports to Tableau.

Configuration template

Use this template to configure the gateway settings.

For more explanation about configuration files, entities, and keys see Configuration File Example.

```
{
  "configKeys": {
    "servercrashupload.enabled": "true",
    "servercrashupload.scheduled_time": "1:00:00 UTC",
    "servercrashupload.proxy_server_host": "",
    "servercrashupload.proxy_server_port": "",
    "servercrashupload.proxy_server_username": "",
    "servercrashupload.proxy_server_password": "",
    "servercrashupload.preserve_upload_packages": "false",
    "servercrashupload.delete_completed_dumps": "false"
  }
}
```

Configuration file reference

This table includes keys that you can set to configure crash reporting.

servercrashupload.enabled

Default: false.

Set to true to enable crash reporting.

`servercrashupload.scheduled_time`

Default: 1:00:00 UTC

Specifies the scheduled time that crash uploads will begin. Enter time of day in 24 hour format.

`servercrashupload.proxy_server_host`

If your organization uses a proxy server to communicate with the internet, specify the host name.

`servercrashupload.proxy_server_port`

If your organization uses a proxy server to communicate with the internet, specify the port number.

`servercrashupload.proxy_server_username`

If your proxy server requires authentication, specify the user name with this key.

`servercrashupload.proxy_server_password`

If your proxy server requires authentication, specify the password with this key.

`servercrashupload.preserve_upload_packages`

Default: false.

To save all packages that are created for a crash reporting, set this key to `true`.

By default, packages are saved to `C:\ProgramData\Tableau\Tableau Server-\data\tabsvc\clustercontroller\tabcrashreporter`.

`servercrashupload.delete_completed_dumps`

Default: false.

To delete all dumps after they are sent, set this key to `true`.

Navigate the Admin Areas of the Tableau Web Environment

As an administrator on Tableau Server or Tableau Cloud, you can access admin settings that aren't available to other users to configure sites, users, projects, and to do other content-related tasks.

The settings in this article refer to the Tableau web environment. Tableau Server administrators with appropriate credentials can also change server settings such as processor, caching, authentication, distributed deployment, and related configurations using the TSM web environment. For information, see [Sign in to Tableau Services Manager Web UI](#).

Access based on site role and number of sites

The menus you get when you sign in to Tableau Server or Tableau Cloud depend on the following conditions:

- Whether you're a site or server administrator.

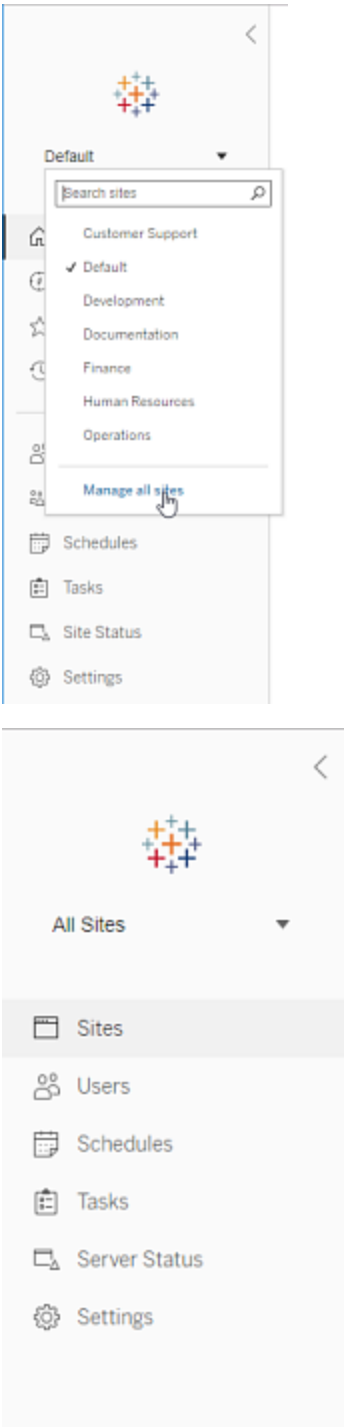

Site administrator access is available on Tableau Cloud and Tableau Server. Server administrator access is only on Tableau Server.

- Whether you have access to only one site or to multiple sites.

Server administrator

<p>On a single-site server, the site selector does not appear, and all other menus are the same.</p>	
<p>In a multi-site environment, menus along the left enable you to modify a specific site or all sites, and to configure users, groups, schedules, tasks, and server settings.</p> <p>To access server administrator settings that affect all sites, open the site menu by clicking the arrow next to the current site name, and then select Manage all sites.</p> <p>The Content and Group tabs go away, and the site menu text changes to All Sites to let you know you are managing server-wide settings, and options like Server Status reflect the server-wide view.</p>	

To return to the site administration menus, select **All Sites**, and then select the site you want to manage.

Site administrator

If you are a site administrator for Tableau Cloud or Tableau Server, and you have access to multiple sites, you'll get menus for selecting which site to manage, and for managing that site's content, users, groups, schedules, and tasks, and for monitoring its status.

The site selector displays the name of the current site. To go to another site, select the site menu, and then select the site name.

If you have access to only one site, the site selector does not appear, but all other menus are the same.

Server administrator tasks

Server administrators (available with Tableau Server Enterprise only) can do the following:

- Monitor server status and activity.
- Generate log files.
- Add sites and edit site settings. Only server administrators can add sites to the server.
- Add users to the server, and assign users to sites.
- Add and manage site groups.
- Add users to or remove users from **identity pools**.

To manage settings only for a specific site, you must first navigate to the site. Within each site, you can do the following:

Tableau Server on Windows Help

- Administer content: Create projects, move content from one project to another, assign permissions, change ownership of a content resource, and so on.
- Manage schedules for extract refreshes and subscriptions.
- Monitor site activity and record workbook performance metrics.
- Manage storage space limits for content published by users.
- Allow web authoring.
- Enable revision history.
- Allow site administrators to add and remove users.
- Set the maximum number of licenses that site can consume for each license type (Creator, Explorer, Viewer).
- Allow users to subscribe to workbooks and views, and allow content owners to subscribe others to workbooks and views.
- Enable offline snapshots for favorites (iOS only).

Site administrator tasks

A site administrator on Tableau Cloud or Tableau Server can do the following tasks:

- Administer content: Create projects, move content from one project to another, assign permissions, change ownership of a content resource, and so on.
- View, manage, and manually run schedules for extract refreshes and subscriptions.
- Add and manage site users (if allowed by the server administrator; see Site Settings Reference).
- Add and manage site groups.
- Monitor site activity.

Move Tableau Server to Another Drive

By default Tableau Server on Windows is installed to the system drive (usually C:\). This means that all program and data files are installed to that drive. If you need to move Tableau Server to a different drive (if a new policy requires you to not have application data on your system drive, for example, or you are running out of space on the original drive), you can do this by following the procedure below. The steps are intended as an example for moving Tableau Server from one drive to another drive on the same computer, and may not exactly reflect your installation and configuration. For instructions on moving Tableau Server to a new computer, see [Migrate to New Hardware](#).

Before you start

Before starting, make sure you:

- Have a current backup of your data and assets from your existing installation as well as a settings export. You'll need these to restore your installation of Tableau Server on the new drive. For details on creating a backup, see [Perform a Full Backup and Restore of Tableau Server](#).

You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.

- Have administrative credentials to the Tableau Server computer. This is where you will be working and you need to be logged on to the computer as an administrator.
- Have a copy of the installation program for the version of Tableau Server you are moving. You need this to install Tableau Server to the new drive.
- Know what authentication methods your current installation is using. For example, if Tableau Server is configured for SSL, SAML, or Kerberos, you will need to back up the

related certificate or keytab files separately, and then copy them to the new drive after you reinstall Tableau Server.

- Know and understand any initial node settings and configuration in your current installation.

When you are ready to move Tableau Server to another drive and have fully backed up your data and all assets and saved those files in a safe location on a different computer:

1. Open a command prompt as an administrator on the initial Tableau Server computer.
2. Change to the scripts directory (By default: `C:\Program Files\Tableau\Tableau Server\packages\scripts.<version_code>\`) and run the `obliterate` script to completely remove Tableau Server from the computer:

```
tableau-server-obliterate.cmd -a -y -y -y
```

3. Restart the computer.
4. Install Tableau Server to the new drive. Do this by running the Setup program. For details, see [Install TSM](#).
5. Activate and register Tableau Server. See [Activate and Register Tableau Server](#).

At the end of the install process a browser window will open and you will be prompted to create an initial administrative user. Close this without creating the user.

6. Configuring initial node settings. See [Configure Initial Node Settings](#)
7. Copy your backup file `.tsbak` to the folder location specified by the `base-filepath.backuprestore` variable. By default this is: `C:\ProgramData\Tableau\Tableau Server\data\tabsvc\files\backups\`

Note: You can change the location for the backup file. For more information, see [tsm File Paths](#).

8. Open a command prompt as an administrator.
9. Stop Tableau Server:

```
tsm stop
```

10. Restore your Tableau Server data backup and assets you saved earlier. This includes restoring your database, and any assets that need to be restored manually, and importing the settings you exported from the original installation.

For details, see [Restoring core Tableau Server functionality](#).

11. Start Tableau Server:

```
tsm start
```

Tableau Server product key activation

You can activate the same Tableau Server product key up to three times. This allows you to test Tableau Server (in a sandbox or QA environments, for example), as well as use Tableau in production. To maximize your activations, you should deactivate your product key when you remove Tableau Server from a computer, unless you will be reinstalling Tableau on the same computer. Doing this gives you the opportunity to use the activation on a different computer. For example, if you move Tableau Server from one computer or VM to another, deactivate the product key, then remove Tableau from the original computer. When you install Tableau on the new computer, you can activate the key there without any conflict. If you use role-based licensing, be sure to activate a Creator or Explorer key or you may lose administrator access to Tableau. If you are removing Tableau Server to reinstall it on the same computer, you don't need to deactivate the key. Tableau will use the key when reinstalled. For example, if you are moving Tableau from one drive on a computer to a different drive on the same computer. For information on how to deactivate a product key, see [tsm licenses deactivate](#).

When you remove Tableau Server using the `obliterate` script, you have the option to have the script deactivate and delete the Tableau product key information by using a `"-1"` switch. This will deactivate and remove all Tableau license information, including Tableau Desktop if you

have that installed. If you know you want to deactivate the key, we recommend you deactivate the key *before* running the script. For more information, see [Remove Tableau Server from Your Computer](#).

Distributed and High Availability Tableau Server Installations

This topic describes different installation deployment types for Tableau Server.

Validating your server deployment plan

Before you commit to installing a new Tableau Server deployment in your organization, be sure to carefully evaluate your options. For most organizations, Tableau Cloud will provide a more reliable, performant, and cost-effective analytics solution when compared to self-hosting Tableau Server. For information about the viability of Tableau Cloud for your organization, review this blog post, [Should I move my analytics to the cloud?](#)

Already running Tableau Server and want to migrate to Tableau Cloud? See [Tableau Cloud Manual Migration Guide](#).

If you have determined that you must self-host Tableau Server, we recommend following the prescribed Tableau deployment in the [Enterprise Deployment Guide](#) (EDG). The EDG presents a fully-tested and supported, performant, scalable, secure reference architecture based on a tiered data network. Moving forward, we are committed to investing in the EDG reference architecture to ease feature rollouts and improve upgrade scenarios.

Installation types

The most basic way to run Tableau Server is to install a single node. With this type of installation you have a fully functional Tableau Server, with all Tableau Services Manager (TSM) and Tableau Server processes running on that single node, but this may not be the optimal way to use Tableau Server. You can decide how to install Tableau based on your organization's

needs, and your resources, adding additional nodes and configuring Tableau for high availability. Your installation options include:

- **Single-node installation**—This type of installation is reasonable for testing, running trials, and for environments that can handle occasional downtime and system availability due to lack of redundancy. All server processes are running on a single machine. There is less redundancy and fewer safeguards in the event of a problem with one of the server processes. You also need to make sure the computer you install Tableau Server on has adequate resources to handle the processes and the demands of users and data.
- **Distributed installation**—This type of installation is also called a multi-node installation and requires multiple computers so you can install and run server processes on those distributed nodes. Spreading the server processes out over multiple nodes can extend the reliability and efficiency of Tableau Server by providing redundancy and additional computing power. With the right configuration, a distributed installation can also provide you with automatic repository failover. For more information on failover, see [Repository Failover](#).
- **Highly available (HA) installation**—An HA installation of Tableau Server is a special type of multi-node installation with a minimum of three nodes and multiple instances of key processes (the Repository, File Store/Data Engine (Hyper), Coordination Service, and Client File Service) on different computers. With an HA installation, there is built-in redundancy of those key processes, including multiple File Stores, and automatic Repository failover. The goal is to minimize system downtime by eliminating single points of failure, and enabling detection of failures with failover where possible.

Downtime is still possible in the event of an initial node failure, or when a node running Application Server (VizPortal) is recovering from a failure. Dashboards and views may load more slowly than expected, and timeouts are possible, depending on how your system is configured and being used. For more information about initial node failure, see [If an initial node fails](#) below.

The first computer you install Tableau on, the "initial node," has some unique characteristics. Three processes run only on the initial node and cannot be moved to any other node except in a failure situation, the License Service (License Manager), Activation Service, and TSM Controller (Administration Controller). Tableau Server includes a script that automates moving these processes to one of your other existing nodes so you can get complete access back to TSM and keep Tableau Server running.

Two other processes are initially included on the initial node but can be added or moved to additional nodes, the CFS (Client File Service) and the Coordination Service. Depending on how your installation was configured with CFS and Coordination Service, you may also need to take steps to redeploy these.

For information about moving the License service and TSM Controller from the initial node to another node, see [Recover from an initial node failure](#) below.

External repository

For optimal performance for Tableau Server we recommend isolating the repository on a dedicated node in your deployment. If you have an Advanced Management license, consider running the repository as an external database.

If your organization has a peak load of more than 1000 VizQL sessions per hour, we also recommend running Tableau Server on Linux. In this scenario, VizQL sessions refer to any user actions that display or generate visualizations from Tableau Server.

For more information, see [Tableau Server External Repository](#).

Prerequisite

These instructions assume that your cluster meets the Distributed Requirements.

Note: All nodes in a multi-node cluster must have the same type of operating system. You cannot install a multi-node instance of Tableau Server on a combination of Linux and Windows nodes.

Licensing

You must have a valid Tableau Server product key. The type of license you have may determine how many nodes you can install Tableau on. For more information on licensing, see [Licensing Overview](#).

Creating a distributed Tableau Server installation

These are the general steps you follow to create a distributed installation of Tableau Server:

1. Begin by installing Tableau Server on your initial node.

For details, see [Install and Configure Tableau Server](#).

2. Generate a node configuration (bootstrap) file on the initial node.

For details, see [Generate the node bootstrap file](#).

3. Install Tableau Server on an additional node using the node bootstrap file.

4. Configure your additional node with the processes you want to run on it.

5. Repeat Steps 3 and 4 for any additional nodes you want to install.

6. Deploy a new Coordination Service ensemble.

For more information, see [Deploy a Coordination Service Ensemble](#).

7. Add Client File Service to every node that is running the Coordination Service.

For more information, see [Configure Client File Service](#).

Creating a highly available (HA) Tableau Server installation

A high availability Tableau Server installation is a special type of distributed installation, designed to accommodate failure in key server components without loss of complete server functionality. To create an HA installation, follow the same steps you take to create a

distributed deployment but include additional steps to make the deployment highly available. These additional steps include adding at least two additional nodes (for a minimum of three nodes in the cluster), adding a second instance of the repository, and second instances of the data engine/file store, adding additional gateway processes, and deploying a Coordination Service ensemble. You can also add a load balancer to distribute requests among the gateways.

At a high level, these are the steps you follow to create a highly available installation of Tableau Server:

1. Begin by installing Tableau Server on your initial node.

For details, see [Install and Configure Tableau Server](#).

2. Generate a node configuration (bootstrap) file on the initial node.

For details, see [Generate the node bootstrap file](#).

3. Install Tableau Server on at least two additional nodes using the node bootstrap file.

For more information, see [Install and initialize an additional node](#).

4. Configure each additional node with the processes you want to run on it. These must include a second copy of the Tableau Server repository, and a second copy of the data engine and file store, as well as additional instances of the gateway.

For more information, see [Configure the additional node](#).

5. Deploy a Coordination Service ensemble.

For more information, see [Deploy a Coordination Service Ensemble](#).

6. Add Client File Service to every node that is running the Coordination Service.

For more information, see [Configure Client File Service](#).

7. (Optional) Configure a load balancer.

For more information, see [Add a Load Balancer](#).

For details on how to create a three-node HA installation, see [Example: Install and Configure a Three-Node HA Cluster](#).

If an initial node fails

If there is a problem with the initial node and you have redundant processes on your other nodes, there is no guarantee that Tableau Server will continue to run.

- Tableau Server can continue to run for up to 72 hours after an initial node failure, before the lack of the licensing service impacts other processes. If so, your users *may* be able to continue to sign in and see and use their content after the initial node fails, but you will not be able to reconfigure Tableau Server because you won't have access to the Administration Controller.
- If you are running a version of Tableau Server 2021.4.2 (or older) that is configured for ATR, then problems with the initial node will render all server functionality unavailable. This is true whether the node has a problem or if you intentionally stop it (for instance, to do a system-level patch).

Even when configured with redundant processes, *it is possible that Tableau Server may not continue to function after the initial node fails*. This is true even when an installation is configured for high availability. This means you should make a point of moving the two unique processes to another of your running nodes as soon as possible. If your initial node fails for reasons that are recoverable in a relatively short amount of time (for example, a hardware failure you can correct), you should first attempt to bring the node back up without using the procedure below.

Recover from an initial node failure

With a Tableau Server installation, the initial node includes two services that are only installed on that node, the License service, and the TSM Controller. If there is a problem with the initial node, Tableau Server may not continue to function, even when configured for high

availability. To recover from a situation where the initial node fails, you can move the TSM Controller and the License service to one of your already configured nodes. This allows you to recover from the failure while using resources you already have in the cluster. You do not have to configure a standby initial node in case the initial node fails.

For details on how to recover from a failure on the initial node, see [Recover from an Initial Node Failure](#).

Configure Coordination Service ensemble on additional nodes

Configuring a Coordination Service on multiple nodes provides additional duplication of processes and so reduces the possibility of server downtime due to an issue with one of the Coordination Service nodes. For details on how to deploy a Coordination Service ensemble on your cluster, see [Deploy a Coordination Service Ensemble](#).

Add Client File Service (CFS) to additional nodes

Tableau Server requires at least one instance of Client File Service (CFS). Adding additional instances of CFS to other nodes provides additional duplication of processes and so reduces the possibility of server downtime due to an issue with one of the CFS nodes. We recommend that you configure an instance of CFS on each of the nodes where you deploy the Coordination Service. For details on how to configure CFS on other nodes, see [Configure Client File Service](#).

Tableau Server service license check

A number of processes are installed when you install Tableau Server. Some of these processes are dependent on the existence of a valid Tableau Server license while other installed processes are not. The subset of Tableau Server that require a valid Tableau Server license are considered "licensed processes."

When a licensed process starts or restarts, the process checks with the Tableau Server License Manager service on the primary node to verify there is a valid license. When the

License Manager validates the license, the process is fully functional and able to respond to requests from other Tableau Server processes. Once a licensed process has received confirmation from the License Manager, the process does not need to reconfirm the license for 72 hours, or until the process restarts. If the process is not able to verify that it is licensed (if the primary node is unavailable, for example) it cannot run, but it continues to check for a valid license until it confirms the license. To see when the last licensing check occurred, look at the log files in the `ProgramData\Tableau\Tableau Server-\data\tabsvc\logs\licenseservice` folder. For more information about licensed processes, see [Licensed processes](#).

Distributed Requirements

Before you start to configure a Tableau Server cluster, make sure you meet the following requirements.

Hardware

While the computers you use in your cluster must meet the requirements described in [Before you install...](#), they do not need to be identical.

Hardware Guidelines for High Availability

Here are some guidelines for the systems you use for [failover and high availability](#):

- **Failover—three computers:** To configure a cluster that provides failover support for the file store and repository processes, you need at least three computers or VMs: one for the initial Tableau Server node and two for additional nodes.
- **Multiple gateways—three computers and a load balancer:** Adding multiple Gateway processes to your Tableau Server installation and using a load balancer to automatically distribute requests to those gateways enhances the reliability of Tableau further. To configure a cluster that provides failover support and multiple gateways, you

need to add a load balancer to front your three-node cluster.

- **Failover & multiple gateway support—three computers and a load balancer:** To configure a cluster that provides the above plus support for multiple gateways, you need at least three computers or VMs, and a load balancer to front the cluster.
- **High availability—three computers and a load balancer:** To configure for high availability, you need the resources described above.
- **Initial computers:** If you configure for high availability, the initial Tableau Server node may be running few or no Tableau Server processes. Therefore, the computer that serves as the initial node does not need as many cores as the ones running your additional nodes. You will, however, need adequate disk space for backups because the initial computer is used during the backup and restore processes. In addition to the amount of space needed for the backup file, you need temporary disk space. For details on disk space requirements, see [Disk Space Usage for Backup and Restore](#).

Software

All nodes in a distributed installation must be running the same version of Tableau Server.

Installation location

The installation location for Tableau Server must be the same on all nodes in a cluster. This is true whether you install to the default location or to a non-default location.

Networking and Ports

- **Ports:** As with any distributed system, the computers or VMs you use need to be able to communicate with one another. For information on how Tableau Services Manager handles port mapping, see [Tableau Services Manager Ports](#).
- **Same domain:** If Tableau Server is installed in a Windows Active Directory environment, then all computers in a cluster must be members of the same domain.

- **Latency:** Network latency between server nodes can impact Tableau Server performance. Be aware of possible latency issues, especially if you run into performance problems. To reduce network latency, you can take steps such as locating your gateways and data sources in proximity to Tableau Server.
- **Service account:** The server's Run As Service Account account, which is specified on the initial Tableau Server, must be the same on each computer in the cluster.

If you are running in an Active Directory environment, then we recommend running a domain user account as the Run As service account. While you can leave the default NetworkServices account on each node in the cluster, we do not recommend this as a best security practice.

If you are running a distributed deployment in a Windows workgroup, then you must use the same user account and password on each node in the cluster. In this scenario, specify the Run As service account using a period (.) instead of a computer name in TSM. For example, if the workgroup Run As service account is `tableau-sa`, then specify `.\tableau-sa` in TSM. Windows interprets the `.\` syntax as equivalent to "local host computer name."

- **Static IP addresses:** Any computer running Tableau Server, whether it's a single server installation or part of a cluster, must have a static IP address.
- **Discoverable:** Each node in the cluster must be discoverable from other node computers using DNS or a local host file.
- **Time zone and time:** Each node in the cluster must be in the same timezone, with their system clocks synchronized. This may happen automatically. For example, if your nodes are all in the Active Directory domain, the domain controller usually handles this. If you are not sure your cluster meets this requirement, consult with your internal IT experts.

Best Practices

Here are some things to keep in mind before you start to install and configure:

- **IP addresses or computer names:** As mentioned above, each computer in the cluster must use a static IP address.
- **CNAME record:** If you are using a load balancer, it's the load balancer's name that users will be using as the Tableau Server URL, regardless of the gateway that's actually handling the request.
- **User account credentials:** For each computer, you need credentials for a user account with local admin permissions.
- **Backup:** It's a best practice to create a backup prior to making significant system changes. See [Back up Tableau Server Data](#) for steps.
- **Distributed deployment across data centers:** We do not recommend installing Tableau Server nodes across distributed data centers. The following examples describe some issues that are common when nodes are distributed between multiple data centers:
 - Disruption in network connectivity between nodes can cause many tasks to fail or for Tableau Server components to become unlicensed.
 - Proxies and firewalls between data centers may impede the ability of the Tableau Server nodes to communicate with each other.
 - Routing traffic between geographically dispersed data centers, can cause latency or bottleneck data transmission, resulting in poor performance and connection timeouts.

SSL

If you are planning to configure SSL for a highly available Tableau Server cluster with multiple gateways and a load balancer ([learn more](#)), make sure that the SSL certificate you use was issued for the load balancer's host name. See [Configure SSL for External HTTP Traffic](#) to and from Tableau Server for other details.

Distributed Installation Recommendations

When you add nodes to a Tableau Server installation, you must decide how many processes to run on each computer. This page provides some general recommendations that are intended only as a starting point.

In addition to these general recommendations, you should also:

- Understand how your organization uses Tableau Server and tune your configuration for your use case—for example, whether you want to optimize for user response or for extract refreshes.
- Perform thorough performance testing to identify the best places to adjust process configuration.

For more information on tailoring a Tableau Server installation to your organization's needs, see [Performance Tuning](#).

For more information on the requirements for a distributed installation and for information on configuring additional nodes, see [Distributed and High Availability Tableau Server Installations](#).

Recommendations for all installations

Although the computers that make up a Tableau Server cluster do not need to have identical hardware, they must all meet the same minimum system requirements. The recommendations on this page assume that the computers where you install Tableau Server have eight cores or more.

The following recommendations apply to all server configurations:

- Run Backgrounder processes on a dedicated computer if you plan on refreshing extracts frequently. Backgrounder processes are generally the most CPU intensive and can slow down other processes on the same computer.

Note: In versions earlier than 10.5, the backgrounder process spun up temporary instances of Data Engine when refreshing extracts. In 10.5, a single instance of Data Engine is installed with the backgrounder during setup. The backgrounder uses this running instance of Data Engine when refreshing extracts.

- If you plan to refresh extracts frequently or if you plan to refresh large extracts, increase the number of processes for Backgrounder processes.
- Run VizQL processes on a different computer than Backgrounder processes. Having them on the same machine means that extract refreshes can affect user views.
- The instance of Data Engine installed on the node where File Store is installed is used for querying data for view requests. Consider separating the File Store process from the backgrounder processes to help minimize the backgrounder tasks from affecting user views.
- **Optimizing with topology configurations:**
 - Co-locating File Store on the same node as the Administration Controller can reduce the length of time it takes to back up Tableau Server by reducing or eliminating the need to transfer data between nodes during the backup process. This is especially true if your organization uses many extracts.
 - Co-locating the repository (pgsql) with the Administration Controller node can also help to reduce back up time, but the time savings is less significant than that of the File Store.

The Administration Controller is usually on the initial node, unless you have had an initial node failure and moved the controller to another node.

Note: In a distributed installation with three or more nodes, you can have a maximum of two repository instances (active and passive). You can also run Tableau Server with one repository, but doing this means there is no failover available for the repository. For more information, see [Tableau Server Repository](#).

Install and Configure Additional Nodes

After you install Tableau Server on one computer (or node), the server is functional and ready for use, but it has no redundancy. If there is a problem with a process or a problem with the computer itself, Tableau Server may be unavailable. In addition, all processes are running on a single computer, so there can be contention for resources on that computer.

You can extend your Tableau Server installation by adding Tableau to additional nodes, creating a distributed installation. This article describes the general steps for installing Tableau Server on additional nodes and assumes you have already installed Tableau on an initial node. For more information on installing Tableau on the initial node, see [Install TSM](#).

If you are installing Tableau Server on multiple nodes, you should install and configure one node at a time. This makes it easier to troubleshoot any issues you might run into.

Important: You should add and configure additional nodes when you can fully complete the process by applying pending changes. Adding a node without finishing by applying pending changes can result in users being unable to log into Tableau Server.

Installation location

The installation location for Tableau Server must be the same on all nodes in a cluster. This is true whether you install to the default location or to a non-default location.

Use the TSM web interface

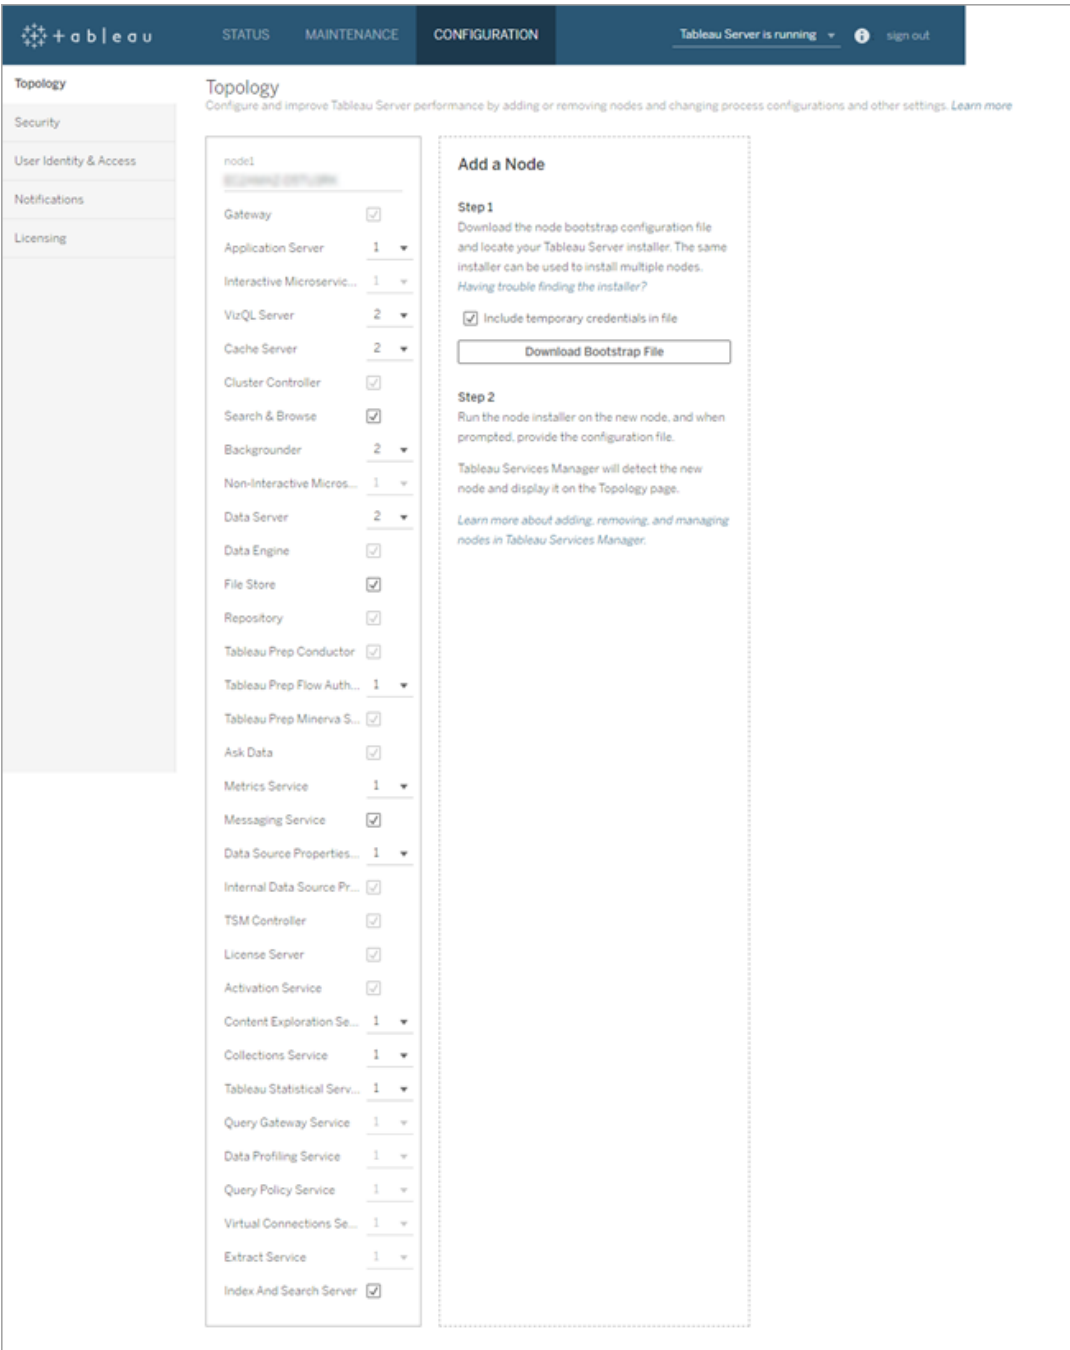

Generate the node bootstrap file

1. Open TSM in a browser:

```
https://<tsm-computer-name>:8850
```

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab, and in the Add a Node box, click **Download Bootstrap File**.

The bootstrap file is created and copied to your local computer.

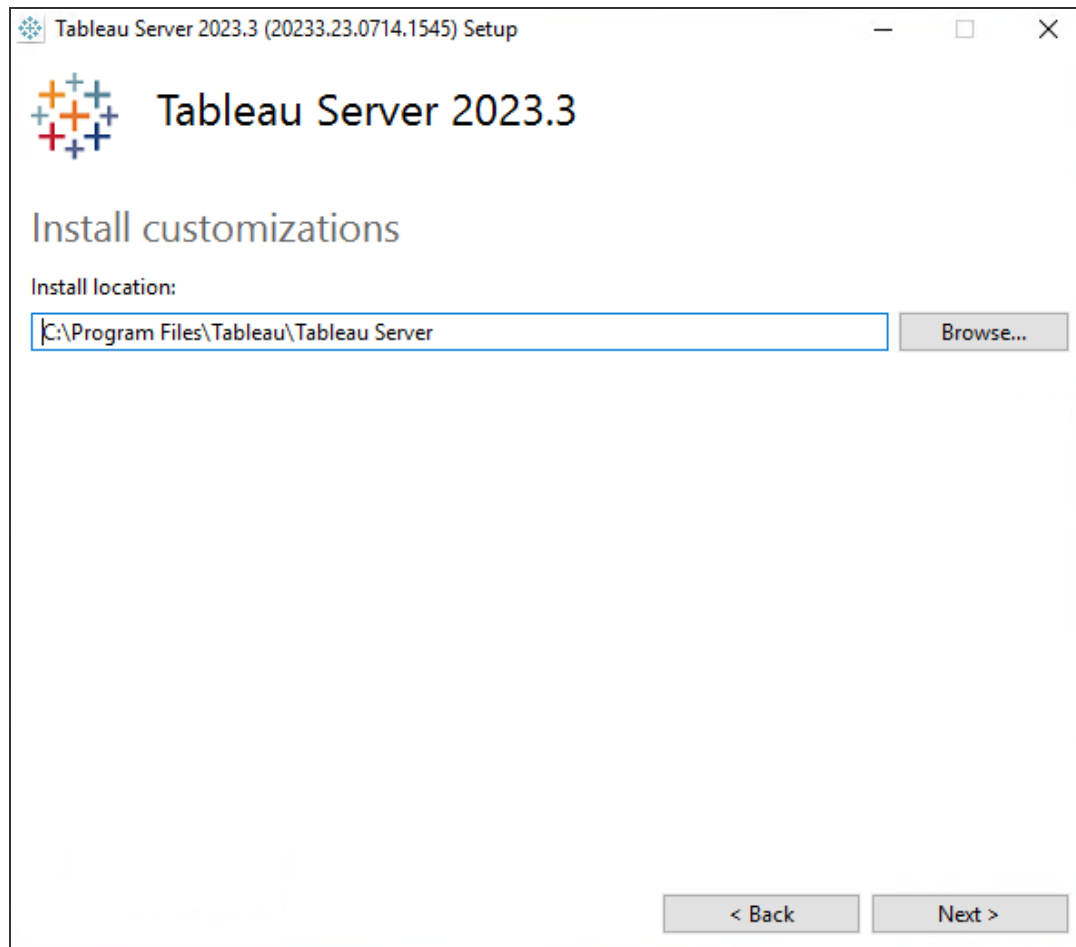

Embedded credentials are included in the bootstrap file by default. If you don't want credentials embedded in the bootstrap file, clear the **Include temporary credentials in file** option. If you want to completely disable the ability to include embedded credentials in node bootstrap files, you can set a configuration option for the server. See `features.PasswordlessBootstrapInit` for more details.

Install and initialize an additional node

Before you begin, verify that your node bootstrap file is recent. For example, if you have run `tsm security regenerate-internal-tokens` after you generated a bootstrap file, then initialization will fail.

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.
2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see [Local firewall configuration](#).
3. On the new node, run the Tableau Server Setup program. This should be the same installer program you ran on the initial node to install Tableau Server. Accept the terms of the license agreement and click **Next**.
4. The **Install location** must be the same on every node in the cluster.

Enter the Install location, or click **Browse** to navigate to the Install location. Click **Next** to continue.

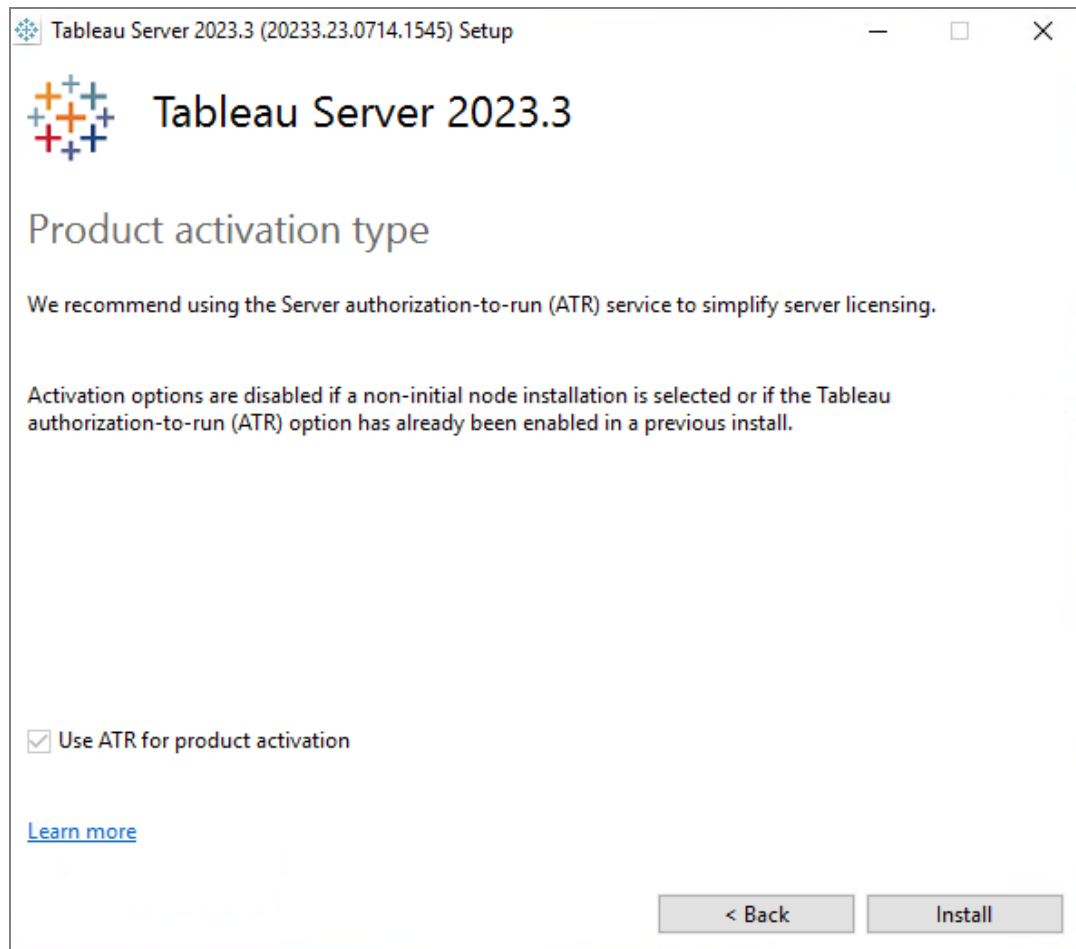

5. During installation you will be asked to select an installation type.

Select **Add additional node to existing Tableau Server cluster** and click **Next** to continue.

6. The **Use ATR for product activation** option which was set for Node 1 will automatically be selected:

Click **Install** to continue.

If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

7. In the installer, after the Tableau Server files are copied, you will be prompted to provide the bootstrap file and the name and password of the TSM administrator:

The dialog box is titled "Node Configuration" and has a blue header bar. Inside, there is a text instruction: "The bootstrap file can be generated by running the 'tsm topology nodes get-bootstrap-file' command on the initial node." Below this, there are three input fields: "Bootstrap File" with a "Browse..." button to its right, "Tableau Services Manager (TSM) Username:" with a text box, and "Tableau Services Manager (TSM) Password:" with a text box. At the bottom right, there are "Next" and "Cancel" buttons.

Enter the location of the bootstrap file, or click **Browse** to navigate to the location. If the bootstrap file does not include embedded credentials, or those credentials have expired, enter the TSM administrator username and password. These credentials must be the credentials of the user that you used during the installation process on the initial node.

Click **Next** to continue.

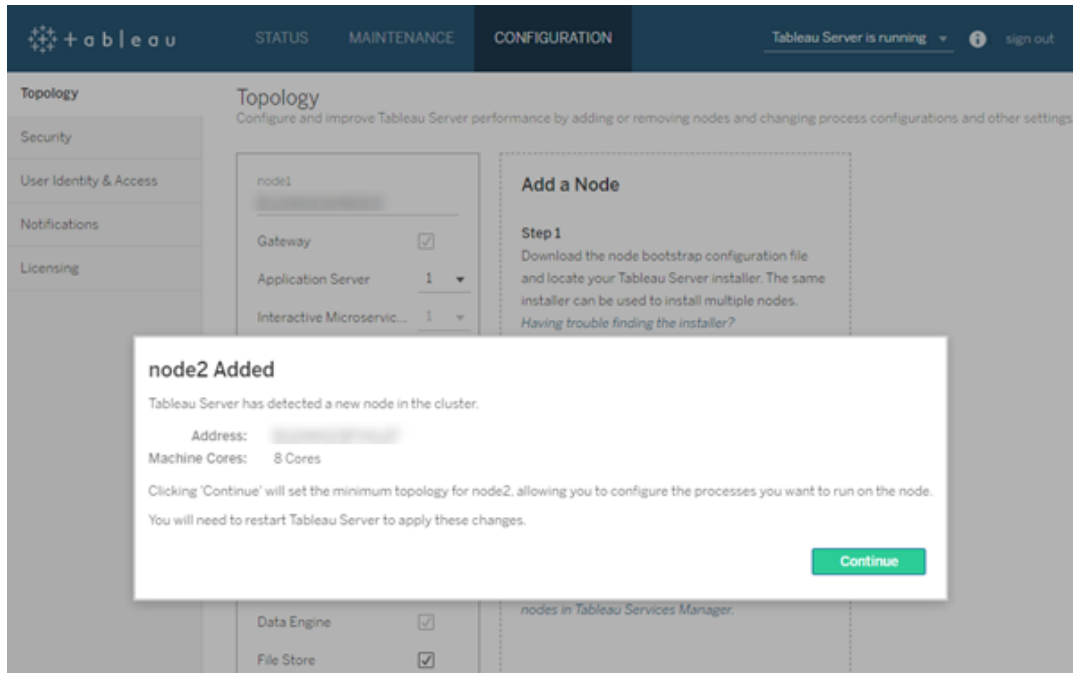

8. A browser window opens and you are prompted to sign in to TSM. Enter the TSM administrator user name and password.

If no browser window opens automatically, open a window and navigate to TSM:

`https://<tsm-computer-name>:8850`

9. In TSM, click **Configuration**.

A message displays, telling you the node was added:

10. Click **Continue**.

Configure the additional node with Cluster Controller

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab. A message should tell you that the new node was added.

Click **Continue** to dismiss the message.

3. Cluster Controller is part of the minimum topology and is already selected. Each node must run Cluster Controller.

If you only want to set the minimum topology for the node, go to Step 4 below. You might do this if you will be adding additional nodes and are not ready to configure this node beyond the minimum.

If you want to add additional processes to the minimum topology, specify the processes that should run on the node. Do this by selecting the processes you want, or specifying the number of processes that should run on the node.

For example, to add a Gateway and two instances of the Backgrounder on the node:

- a. Select **Gateway**.
- b. Set the **Backgrounder** count to 2.

Tableau Server on Windows Help

Adding Backgrounder to a node will also add an instance of Data Engine if one is not already on the node.

The specific processes and process counts you set will depend on your organizational environment and needs. Some processes are added automatically when you add another process. For more information, see [Configure Nodes and Tableau Server Processes](#).

Note: The TSM Web UI limits you to a maximum of 8 instances of processes that allow you to select the number of instances. To configure more instances than this, use the command line and the `tsm topology set-process` command. For more information, see `tsm topology set-process`.

4. Click **Pending Changes** at the top of the page:

If you are configuring a cluster with three or more nodes, a Coordination Service ensemble warning displays. You can continue. You will deploy a Coordination Service ensemble in a separate step.

5. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

After Tableau Server restarts, the node is included with the minimum topology necessary and any additional processes you configured.

Use the TSM CLI

Note: This method of installation from the command line requires you to set Windows environment variables on each additional node for the username and password of an

administrator on the initial node. For an alternate method of automating Tableau Server installation without including unencrypted credentials, see Automated Installation of Tableau Server.

Generate the node bootstrap file

To install Tableau Server on additional computers you use the same installer you did for the initial node, along with a "bootstrap" file you generate on the initial node.

Important: The bootstrap file contains a copy of the master keystore file used for encrypting the configuration secrets. The file can also embed credentials which are valid for a pre-determined amount of time (see `tabadmincontroller.auth.expiration.minutes`) and serve as a session cookie. We strongly recommend that you take additional measures to secure the bootstrap file.

1. After installing Tableau Server on the initial node, generate the node bootstrap file.
2. On the initial node, open a command prompt as administrator.
3. Type this command to generate the bootstrap file:

```
tsm topology nodes get-bootstrap-file --file <path\file>.json
```

Embedded credentials are included in the bootstrap file by default. If you don't want the bootstrap file to include credentials, use the `-nec` or `--no-embedded-credentials` option:

```
tsm topology nodes get-bootstrap-file --file <path\file>.json -  
-no-embedded-credentials.
```

If you want to completely disable the ability to include embedded credentials in node bootstrap files, you can set a configuration option for the server. See `features.PasswordlessBootstrapInit` for more details.

Tableau Server on Windows Help

Install and initialize an additional node

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.
2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see [Local firewall configuration](#).
3. On the new node, run the Tableau Server Setup program. This should be the same installer program you ran on the initial node to install Tableau Server.

```
TableauServer-64bit-<version>.exe /silent /accepteula /embed-  
dedcredential /bootstrapfile="path\bootstrapfile"
```

For more information about switches you can use with the Setup program, see [Install Switches and Properties for Tableau Server](#).

Configure the additional node

Note: This basic example illustrates how to set the topology on a node. For a more detailed, working multi-node example, see [Example: Install and Configure a Three-Node HA Cluster](#).

On the initial (original) node, set the topology for the newly added node. The topology specifies which processes should run on the node, and how many instances of each process should run. The topology for the node will depend on your environment and organizational needs. The below are just examples of setting the topology.

1. On the initial (original) node, open a command prompt.
2. Get the node-id for the new node:

```
tsm topology list-nodes -v
```

The `-v` option lists the nodes and the processes they are currently running. You can identify the newly added node because it will not have any processes on it.

3. Specify the individual processes that should run on this node.

Do this with the following command:

```
tsm topology set-process -n <nodeID> -pr <processname> -c <n>
```

You must add an instance of the Cluster Controller to each node.

For example, to add the Cluster Controller, two instances of the Backgrounder, and a Gateway to node2:

```
tsm topology set-process -n node2 -pr clustercontroller -c 1
tsm topology set-process -n node2 -pr backgrounder -c 2
tsm topology set-process -n node2 -pr gateway -c 1
```

The specific processes and process counts you set will depend on your organizational environment and needs. Some processes are added automatically when you add another process. For more information, see [Configure Nodes and Tableau Server Processes](#).

4. Apply the node configuration. If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see [tsm pending-changes apply](#).

```
tsm pending-changes apply
```

A warning about deploying a Coordination Service ensemble displays if you have deployed a three- or five-node cluster. If this is the only warning, you can safely over-

ride it using the `--ignore-warnings` option to apply the configuration changes in spite of the warning.

```
tsm pending-changes apply --ignore-warnings
```

Install drivers

You need to install drivers so that Tableau Server can connect to data and run extracts. Install these drivers on nodes that are running any of the following processes:

- VizQL Server (vizqlserver)
- Application Server (vizportal)
- Data Server (dataserver)
- Backgrounder (backgrounder)

Drivers and administrative views

If you want to use the built-in administrative views in Tableau Server, you also need to install the PostgreSQL driver on any nodes running any of the above processes.

For more information, see Database Drivers.

Install Tableau Resource Monitoring Tool Agent

If you are using Resource Monitoring Tool to monitor Tableau Server Performance, when you add a new node, you must also install the Resource Monitoring Tool. For more information, see Tableau Server Topology Changes.

Database Drivers

Tableau connectors require a driver to talk to the database. Before you can connect to data sources from Tableau Server, you must install drivers for the data sources you want to connect to. You can find driver links and installation instructions for all the supported connectors on the [Driver Download page](#).

Important: Beginning with version 2023.1.0 you must install the PostgreSQL driver if you want to use the built-in administrative views. You can find this on the [Driver Download page](#).

Install drivers in a cluster

You need to install the drivers for your data sources on the initial node in a Tableau Server cluster. If you install Tableau Server on multiple nodes, you must also install drivers on any node that runs any of the following processes:

- Application Server (Vizportal)
- Backgrounder
- Data Server
- VizQL Server

Example: Install and Configure a Three-Node HA Cluster

A multi-node high availability installation of Tableau Server can help to maximize the efficiency and availability of Tableau Server. When configuring a multi-node Tableau Server deployment, the steps you perform are designed to build in redundancy, helping to reduce your potential downtime. In addition to simply improving efficiency by moving or adding server processes to additional nodes, you can create a highly available (HA) installation of Tableau Server by satisfying these requirements:

- Add additional nodes for a total of at least three nodes
- Deploy a Coordination Service ensemble on at least three nodes
- Add an instance of Client File Service (CFS) on at least one additional node (we recommend adding an instance on each node running the Coordination Service)
- Add a second instance of the File Store on one of the additional nodes (Data Engine will be installed automatically, if it is not already on the node)
- Add a second instance of the Repository (pgsql) on one of the additional nodes

A Tableau Server installation that includes these additions will have built-in redundancy and can support failover in the event of a problem with the repository. This example shows how to do this, and more.

A Single Server System

After installing Tableau Server on an initial node, you have a system that is running everything it needs to function. It has at least one instance of all server processes and is the most basic configuration of Tableau Server. It has no redundancy. The server topology looks like this (some TSM-specific processes are not shown):

A Three-Node System

To build in redundancy, you need to add additional nodes to host instances of the repository and the data engine and file store processes. You can add instances of other processes, including multiple instances of a process on a node. In addition, to reduce the system's vulnerability, you can run multiple gateways and additional instances of some of the server processes. The fewest number of computers required to achieve this configuration is three.

In the diagram below, the file store process has been added to both additional nodes. A second, passive instance of the repository has also been added to one of the other new nodes. Finally, the server processes (shown in blue) have been added to the additional nodes to provide redundancy.

Configuration steps

This procedure describes how to configure a three-node HA Tableau Server cluster with two repository instances and two file store/data engine instances on the additional nodes as pictured above.

Before you begin

Before you install Tableau Server on any additional nodes, ensure that each additional node meets the distributed requirements. See [Distributed Requirements](#) for details.

Use the TSM web interface

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

Step 1: Install the initial node

See [Install and Configure Tableau Server](#).

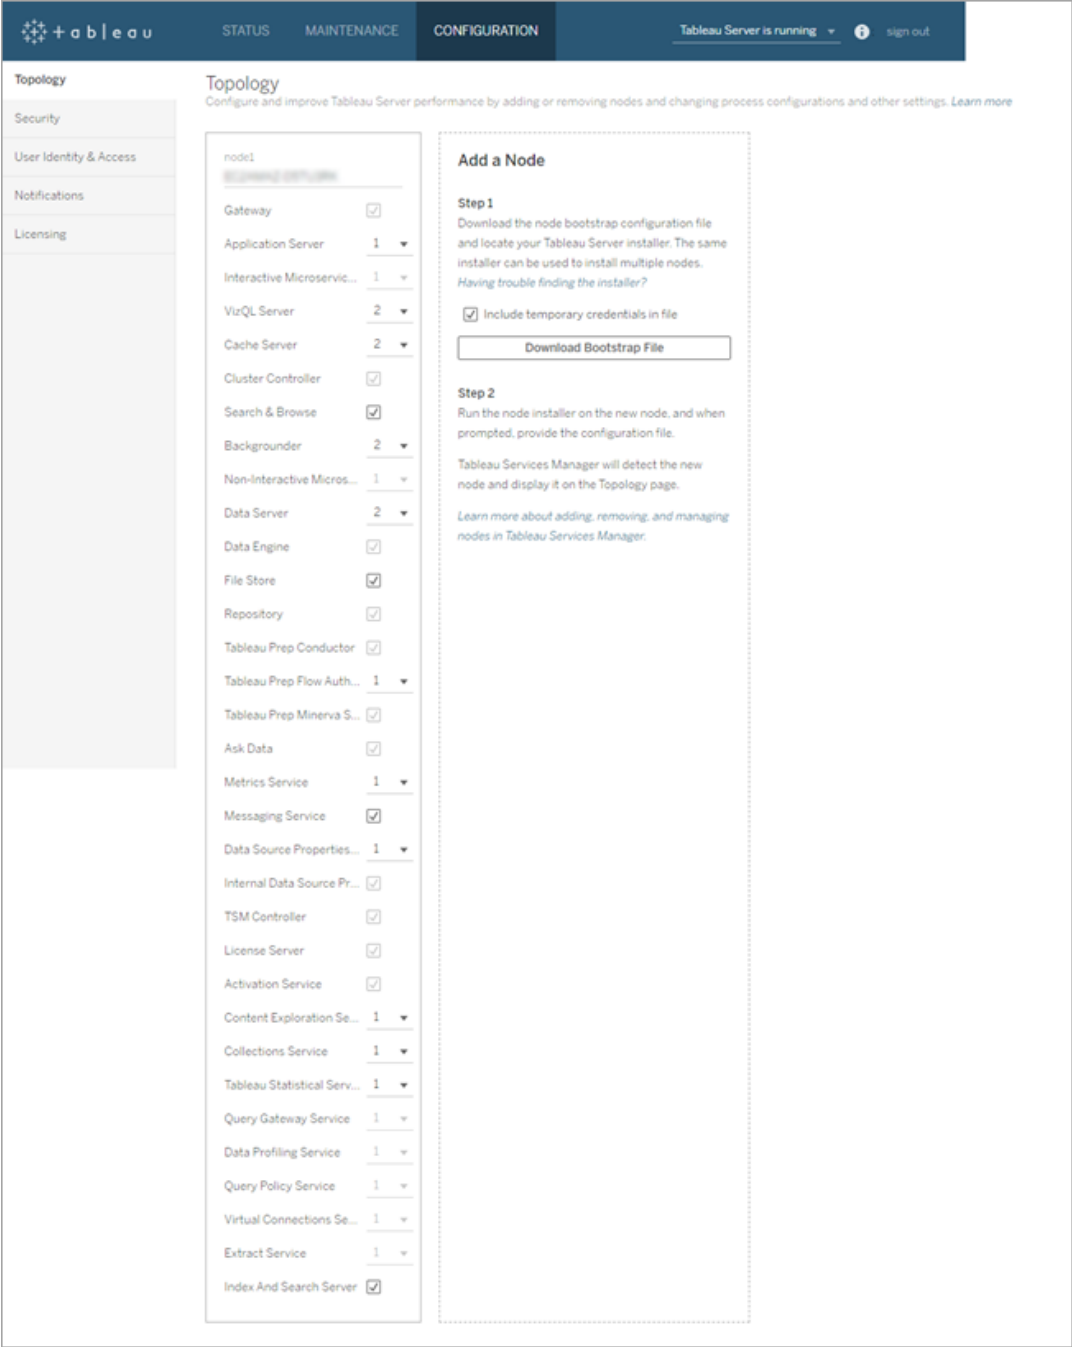

Step 2: Generate a bootstrap file for the additional nodes

1. Open TSM in a browser:

```
https://<tsm-computer-name>:8850
```

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab, and in the Add a Node box, click **Download Bootstrap File**.

The bootstrap file is created and copied to your local computer.

Embedded credentials are included in the bootstrap file by default. If you don't want credentials embedded in the bootstrap file, clear the **Include temporary credentials in**

file option. If you want to completely disable the ability to include embedded credentials in node bootstrap files, you can set a configuration option for the server. See `features.PasswordlessBootstrapInit` for more details.

Step 3: Install and initialize node 2

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.
2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see [Local firewall configuration](#).
3. On the new node, run the Tableau Server Setup program. This should be the same installer program you ran on the initial node to install Tableau Server. Accept the terms of the license agreement and click **Next**.
4. The **Install location** must be the same on every node in the cluster.

Enter the Install location, or click **Browse** to navigate to the Install location. Click **Next** to continue.

5. During installation you will be asked to select an installation type.

Select **Add additional node to existing Tableau Server cluster** and click **Next** to continue.

6. The **Use ATR for product activation** option which was set for Node 1 will automatically be selected:

Click **Install** to continue.

If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

7. In the installer, after the Tableau Server files are copied, you will be prompted to provide the bootstrap file and the name and password of the TSM administrator:

The dialog box is titled "Node Configuration" and has a blue border. It contains the following elements:

- A text box with the message: "The bootstrap file can be generated by running the "tsm topology nodes get-bootstrap-file" command on the initial node."
- A label "Bootstrap File" above a text input field.
- A "Browse..." button to the right of the Bootstrap File input field.
- A label "Tableau Services Manager (TSM) Username:" above a text input field.
- A label "Tableau Services Manager (TSM) Password:" above a text input field.
- "Next" and "Cancel" buttons at the bottom right.

Enter the location of the bootstrap file, or click **Browse** to navigate to the location. If the bootstrap file does not include embedded credentials, or those credentials have expired, enter the TSM administrator username and password. These credentials must be the credentials of the user that you used during the installation process on the initial node.

Click **Next** to continue.

8. A browser window opens and you are prompted to sign in to TSM. Enter the TSM administrator user name and password.

If no browser window opens automatically, open a window and navigate to TSM:

`https://<tsm-computer-name>:8850`

9. In TSM, click **Configuration**.

A message displays, telling you the node was added:

10. Click **Continue**.

Step 4: Install and initialize node 3

Repeat Step 3 above.

Step 5: Configure the new node with a minimum topology

To complete the process of adding new nodes to your cluster, you need to configure them with a minimum topology. With a minimum topology, the only pending change will be the addition of Cluster Controller, which is required on each node. If you want other processes on the nodes you can add most of them at the same time. This example only configures the nodes with Cluster Controller.

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab. A message should tell you that new nodes were added.

Click **Continue** to dismiss the message.

3. Click **Pending Changes** at the top of the page:

If you are configuring a cluster with three or more nodes, a Coordination Service ensemble warning displays. You can continue. You will deploy a Coordination Service ensemble in a separate step.

4. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

When Tableau Server restarts, the nodes are included with the minimum topology necessary.

Step 6: Deploy a Coordination Service ensemble

If you install a total of three or more nodes, you should also deploy a Coordination Service ensemble. If you do not, you will get a warning message every time you make changes to the server configuration or topology. You can ignore this message, but as a best practice you should deploy a multi-node Coordination Service ensemble.

When you install Tableau Server, a single instance of the Coordination Service is installed on the initial node. TSM and Tableau Server depend on the Coordination Service to function properly, so to provide redundancy and ensure availability on multi-node installations, configure additional instances of the Coordination Service by deploying a Coordination Service ensemble. Coordination Service ensembles are installed with one, three, or five instances of the Coordination Service. In a three-node installation of Tableau Server, the recommended number of Coordination Service instances is three, one on each node.

Do not attempt to deploy a Coordination Service ensemble if there are other changes pending. Discard or apply any pending changes before deploying a new Coordination Service ensemble.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

The following steps illustrate how to deploy a new Coordination Service ensemble on an existing three-node Tableau Server cluster and clean up the old ensemble.

1. On the initial node, open a command prompt as administrator.
2. Stop Tableau Server:

```
tsm stop
```

If prompted, sign in as a TSM administrator.

Some TSM processes will continue to run, including the Administration Controller and Administration Agent.

3. Confirm there are no pending changes:

```
tsm pending-changes list
```

If there are pending changes, you need to either discard the changes or apply them.

Applying pending changes will take some time:

- Discard the changes

```
tsm pending-changes discard
```

or

- Apply the changes:

```
tsm pending-changes apply
```

Wait until the command completes and you are returned to the system prompt.

4. Get the node IDs for each node in the cluster:

```
tsm topology list-nodes -v
```

5. Use the `tsm topology deploy-coordination-service` command to add a new Coordination Service ensemble by adding the Coordination Service to specified nodes. You must specify the node(s) that the Coordination Service should be added to, using the actual node ID to identify each node. The command also makes the new ensemble the "production" ensemble (the ensemble in use) and removes the old ensemble, unless the deployment fails. If this happens, see step 6 below.

Note: A "y/n" prompt displays confirming that a server restart will take place. To run the command without input, include the `--ignore-prompt` option.

For example, deploy the Coordination Service to all three nodes of a three-node cluster, where the nodes are node1, node2, and node3:

```
tsm topology deploy-coordination-service -n node1,node2,node3
```

Wait until the command completes and you are returned to the system prompt.

6. (Optional) If the deployment fails, you need to run the `tsm topology cleanup-coordination-service` command to remove the unsuccessfully deployed ensemble. For details on running the command, see `tsm topology cleanup-coordination-service`.

7. Start Tableau Server:

```
tsm start
```

For more information and details on deploying a new Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#).

Step 7: Configure Client File Services (CFS) on additional nodes

Add CFS to additional nodes. We recommend you add CFS to every node running the Coordination Service.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are adding CFS to:

```
tsm topology list-nodes -v
```

3. Add CFS on the node by specifying the node, the process, and a single instance.

For example, this command adds an instance of CFS to node2:

```
tsm topology set-process -n node2 -pr clientfileservice -c 1
```

If you attempt to add an instance of CFS to a node that already is configured with CFS, an error message will let you know there is already an instance on the node.

To add CFS to additional nodes, repeat this step for each node.

4. Apply the changes:

```
tsm pending-changes apply
```

Step 8: Configure processes for node 2

1. Open TSM in a browser:

```
https://<tsm-computer-name>:8850
```

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab.
3. Specify the processes and number of instances that should run on the first additional node.

In this example:

- a. Select **Gateway**.
- b. Set the **Application Server** (vizportal) count to 2.
- c. Set the **VizQL Server** count to 2.
- d. Set the **Cache Server** count to 2.
- e. Set the **Backgrounder** count to 2.

Tableau Server on Windows Help

Adding Backgrounder to a node will also add an instance of Data Engine if one is not already on the node.

- f. Set the **Data Server** count to 2.
- g. Select **File Store**.
- h. Select **Repository** (pgsql).
- i. Select **Metrics Service**.
- j. Select **Messaging Service**.
- k. Select **Data Source Properties**.
- l. Select **Content Exploration Service**.
- m. Select **Collections Service**.
- n. Select **Search and Index Server**.

The specific processes and process counts you set will depend on your organizational environment and needs. Some processes are added automatically when you add another process. For more information, see [Configure Nodes and Tableau Server Processes](#).

Note: The TSM Web UI limits you to a maximum of 8 instances of processes that allow you to select the number of instances. To configure more instances than this, use the command line and the `TSM topology set-process` command. For more information, see [tsm topology set-process](#).

Step 9: Configure processes for node 3

1. In TSM, on the **Configuration** tab, specify the processes and number of instances that should run on the second additional node.

In this example:

- a. Select **Gateway**.
- b. Set the **Application Server** (vizportal) count to 2.
- c. Set the **VizQL Server** count to 2.
- d. Set the **Cache Server** count to 2.
- e. Set the **Backgrounder** count to 2.

Adding Backgrounder to a node will also add an instance of Data Engine if one is not already on the node.

- f. Set the **Data Server** count to 2.
- g. Select **File Store**.
- h. Select **Metrics Service**.
- i. Select **Data Source Properties**.
- j. Select **Content Exploration Service**.
- k. Select **Collections Service**.
- l. Select **Search and Index Server**.

2. Click **Pending Changes** at the top of the page:

The Pending Changes list displays.

3. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

Use the TSM CLI

Note: This method of installation from the command line requires you to set Windows environment variables on each additional node for the username and password of an administrator on the initial node. For an alternate method of automating Tableau Server installation without including unencrypted credentials, see Automated Installation of Tableau Server.

Step 1: Install the initial node

See [Install and Configure Tableau Server](#).

Step 2: Generate a bootstrap file for the additional nodes

To install Tableau Server on additional computers you use the same installer you did for the initial node, along with a "bootstrap" file you generate on the initial node.

Important: The bootstrap file contains a copy of the master keystore file used for encrypting the configuration secrets. The file can also embedded credentials which are valid for a pre-determined amount of time (see `tabadmincontroller.auth.expiration.minutes`) and serve as a session cookie. We strongly recommend that you take additional measures to secure the bootstrap file.

1. After installing Tableau Server on the initial node, generate the node bootstrap file.
2. On the initial node, open a command prompt as administrator.
3. Type this command to generate the bootstrap file:

```
tsm topology nodes get-bootstrap-file --file <path\file>.json
```

Embedded credentials are included in the bootstrap file by default. If you don't want the bootstrap file to include credentials, use the `-nec` or `--no-embedded-credentials` option:

```
tsm topology nodes get-bootstrap-file --file <path\file>.json -
-no-embedded-credentials.
```

If you want to completely disable the ability to include embedded credentials in node bootstrap files, you can set a configuration option for the server. See [features.PasswordlessBootstrapInit](#) for more details.

Step 3: Install and initialize node 2

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.
2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see [Local firewall configuration](#).
3. On the new node, run the Tableau Server Setup program. This should be the same installer program you ran on the initial node to install Tableau Server.

```
TableauServer-64bit-<version>.exe /silent /accepteula /embed-
dedcredential /bootstrapfile="path\bootstrapfile"
```

For more information about switches you can use with the Setup program, see [Install Switches and Properties for Tableau Server](#).

Step 4: Install and initialize node 3

Install Tableau Server on node 3:

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.

2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see [Local firewall configuration](#).
3. On the new node, run the Tableau Server Setup program. This should be the same installer program you ran on the initial node to install Tableau Server.

```
TableauServer-64bit-<version>.exe /silent /accepteula /embeddedcredential /bootstrapfile="path\bootstrapfile"
```

For more information about switches you can use with the Setup program, see [Install Switches and Properties for Tableau Server](#).

Step 5: Add a process to the additional nodes

1. On the initial node, configure a cluster controller instance on each additional node:

```
tsm topology set-process -n <nodeID_second-node> -pr cluster-controller -c 1
```

```
tsm topology set-process -n <nodeID_third-node> -pr cluster-controller -c 1
```

2. Apply the node configuration changes:

```
tsm pending-changes apply --ignore-warnings
```

A warning about deploying a Coordination Service ensemble displays because you have deployed a three-node cluster. Use the `--ignore-warnings` option to apply the configuration changes in spite of the warning. You will deploy a new Coordination Service ensemble in the next step.

Step 6: Deploy a Coordination Service ensemble

If you install a total of three or more nodes, you should also deploy a Coordination Service ensemble. If you do not, you will get a warning message every time you make changes to the server configuration or topology. You can ignore this message, but as a best practice you should deploy a multi-node Coordination Service ensemble.

When you install Tableau Server, a single instance of the Coordination Service is installed on the initial node. TSM and Tableau Server depend on the Coordination Service to function properly, so to provide redundancy and ensure availability on multi-node installations, configure additional instances of the Coordination Service by deploying a Coordination Service ensemble. Coordination Service ensembles are installed with one, three, or five instances of the Coordination Service. In a three-node installation of Tableau Server, the recommended number of Coordination Service instances is three, one on each node.

Do not attempt to deploy a Coordination Service ensemble if there are other changes pending. Discard or apply any pending changes before deploying a new Coordination Service ensemble.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

The following steps illustrate how to deploy a new Coordination Service ensemble on an existing three-node Tableau Server cluster and clean up the old ensemble.

1. On the initial node, open a command prompt as administrator.
2. Stop Tableau Server:

```
tsm stop
```

If prompted, sign in as a TSM administrator.

Some TSM processes will continue to run, including the Administration Controller and Administration Agent.

3. Confirm there are no pending changes:

```
tsm pending-changes list
```

If there are pending changes, you need to either discard the changes or apply them.

Applying pending changes will take some time:

- Discard the changes

```
tsm pending-changes discard
```

or

- Apply the changes:

```
tsm pending-changes apply
```

Wait until the command completes and you are returned to the system prompt.

4. Get the node IDs for each node in the cluster:

```
tsm topology list-nodes -v
```

5. Use the `tsm topology deploy-coordination-service` command to add a new Coordination Service ensemble by adding the Coordination Service to specified nodes. You must specify the node(s) that the Coordination Service should be added to, using the actual node ID to identify each node. The command also makes the new ensemble the "production" ensemble (the ensemble in use) and removes the old ensemble, unless the deployment fails. If this happens, see step 6 below.

Note: A "y/n" prompt displays confirming that a server restart will take place. To run the command without input, include the `--ignore-prompt` option.

For example, deploy the Coordination Service to all three nodes of a three-node cluster, where the nodes are node1, node2, and node3:

```
tsm topology deploy-coordination-service -n node1,node2,node3
```

Wait until the command completes and you are returned to the system prompt.

6. (Optional) If the deployment fails, you need to run the `tsm topology cleanup-coordination-service` command to remove the unsuccessfully deployed ensemble. For details on running the command, see [tsm topology cleanup-coordination-service](#).

7. Start Tableau Server:

```
tsm start
```

For more information and details on deploying a new Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#).

Step 7: Configure Client File Services (CFS) on additional nodes

Add CFS to additional nodes. We recommend you add CFS to every node running the Coordination Service.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are adding CFS to:

```
tsm topology list-nodes -v
```

3. Add CFS on the node by specifying the node, the process, and a single instance.

For example, this command adds an instance of CFS to node2:

```
tsm topology set-process -n node2 -pr clientfileservice -c 1
```

If you attempt to add an instance of CFS to a node that already is configured with CFS, an error message will let you know there is already an instance on the node.

To add CFS to additional nodes, repeat this step for each node.

4. Apply the changes:

```
tsm pending-changes apply
```

Step 8: Configure processes for node 2

1. On the initial node, set the topology for node 2. The topology specifies which processes should run on the node, and how many instances of each process should run. For details about configuring nodes, see [Configure Nodes](#). Data engine will be added automatically when you add other processes. For details on when data engine is added, see [Tableau Server Processes](#).

- a. Get the node-id for the new node: `tsm topology list-nodes -v`

- b. Specify individual processes that will run on the new node:

```
tsm topology set-process -n <node-id> -pr gateway -c 1
```

```
tsm topology set-process -n <node-id> -pr vizqlserver -c 2
```

```
tsm topology set-process -n <node-id> -pr vizportal -c 2
```

```
tsm topology set-process -n <node-id> -pr backgrounder -c 2
```

```
tsm topology set-process -n <node-id> -pr cacheserver -c 2
```

```
tsm topology set-process -n <node-id> -pr index-  
andsearchserver -c 1
```

```
tsm topology set-process -n <node-id> -pr dataserver -c 2
```

```
tsm topology set-process -n <node-id> -pr filestore -c 1
```

```
tsm topology set-process -n <node-id> -pr pgsql -c 1
```

```

tsm topology set-process -n <node-id> -pr metrics -c 1

tsm topology set-process -n <node-id> -pr activemqserver -
c 1

tsm topology set-process -n <node-id> -pr tdsservice -c 1

tsm topology set-process -n <node-id> -pr con-
tentexploration -c 1

tsm topology set-process -n <node-id> -pr collections -c 1

```

2. Apply the node configuration changes. You will be prompted with a message that Tableau Server will restart.

```
tsm pending-changes apply
```

Step 9: Configure processes for node 3

On the initial node, set the topology for node 3. The topology specifies which processes should run on the node, and how many instances of each process should run. Data engine will be added automatically when you add other processes. For details on when data engine is added, see [Tableau Server Processes](#).

1. Get the node-id for the new node:

```
tsm topology list-nodes -v
```

2. Specify individual processes that will run on the new node:

```

tsm topology set-process -n <node-id> -pr gateway -c 1

tsm topology set-process -n <node-id> -pr vizqlserver -c 2

tsm topology set-process -n <node-id> -pr vizportal -c 2

tsm topology set-process -n <node-id> -pr backgrounder -c 2

tsm topology set-process -n <node-id> -pr cacheserver -c 2

```

Tableau Server on Windows Help

```
tsm topology set-process -n <node-id> -pr indexandsearchserver  
-c 1
```

```
tsm topology set-process -n <node-id> -pr dataserver -c 2
```

```
tsm topology set-process -n <node-id> -pr filestore -c 1
```

```
tsm topology set-process -n <node-id> -pr metrics -c 1
```

```
tsm topology set-process -n <node-id> -pr tdsservice -c 1
```

```
tsm topology set-process -n <node-id> -pr contentexploration -c  
1
```

```
tsm topology set-process -n <node-id> -pr collections -c 1
```

3. Apply the node configuration. You will be prompted with a message that Tableau Server will restart.

```
tsm pending-changes apply
```

4. Start the server:

```
tsm start
```

Step 10: Configure firewall rules (optional)

If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see [Local firewall configuration](#) .

Add a Load Balancer

At this point, all three nodes have gateways, which are used to route requests to available server processes. All gateways are active, but to further reduce the potential for downtime in the cluster, you can configure a load balancer. For more information, see [Add a Load Balancer](#).

Add a Load Balancer

You can enhance the reliability of Tableau Server by running gateways on multiple nodes, and configuring a load balancer to distribute requests across the gateways. Unlike the repository process, which can be active or passive, all gateway processes are active. If one gateway in a cluster becomes unavailable, the load balancer stops sending requests to it. The load balancer algorithm you choose determines how the gateways will route client requests.

- **Kerberos:** If you will be using Kerberos authentication, you need to configure Tableau Server for your load balancer before you configure Tableau Server for Kerberos. For more information, see [Configure Kerberos](#).

Microsoft SSPI authentication is not supported with a load balancer.

- **Tested load balancers:** Tableau Server clusters with multiple gateways have been tested with Apache and F5 load balancers.

If you are using an Apache load balancer and creating custom administrative views, you need to connect directly to the Tableau Server repository. You cannot connect through the load balancer.

- **Tableau Server URL:** When a load balancer is in front of a Tableau Server cluster, the URL that's accessed by Tableau Server users belongs to the load balancer, not the initial Tableau Server node.
- **Single load balancer endpoint:** You must configure your load balancers for a single URL endpoint. You cannot configure different endpoint hosts to redirect to the same Tableau Server deployment. The single external URL is defined in `gateway.public.host` when you configure Tableau Server, as described in [Configuring Proxies and Load Balancers for Tableau Server](#).
- **Trusted host settings:** The computer running the load balancer must be identified to Tableau Server as a trusted host, as described in [Configuring Proxies and Load Balancers for Tableau Server](#).

Configure Tableau Server to work with a load balancer

The settings used to identify a load balancer to Tableau Server are the same ones that are used to identify a reverse proxy server. If your Tableau Server cluster requires both a proxy server and a load balancer, both must use a single external URL defined in `gateway.public.host` and all proxy servers and load balancers must be specified in `gateway.trusted` and `gateway.trusted_hosts`. See [Configuring Proxies and Load Balancers for Tableau Server](#).

Deploy a Coordination Service Ensemble

The Coordination Service is built on [Apache ZooKeeper](#), an open-source project, and coordinates activities on the server, guaranteeing a quorum in the event of a failure, and serving as the source of "truth" regarding the server topology, configuration, and state. The service is installed automatically on the initial Tableau Server node, but no additional instances are installed as you add additional nodes. Because the successful functioning of Tableau Server depends on a properly functioning Coordination Service, we recommend that for server installations of three or more nodes, you add additional instances of the Coordination Service by deploying a new Coordination Service ensemble. This provides redundancy and improved availability in the event that one instance of the Coordination Service has problems.

Important: The process to deploy a Coordination Service ensemble changed as of version 2020.1.0. If you are running an earlier version of Tableau Server, see the documentation for that version. You can find documentation for all supported versions here: [Tableau Help](#)

- Hardware requirements
- The Coordination Service Quorum
- Deploy a new Coordination Service ensemble

Hardware requirements

The hardware you use for Tableau Server can have an effect on how well the Coordination Service runs. In particular:

- **Memory.** The Coordination Service maintains state information in memory. By design, the memory footprint is small, and is typically not a factor in overall server performance.
- **Disk speed.** Because the service stores state information on disk, it benefits from fast disk speed on the individual node computers.
- **Connection speed** between nodes. The service communicates continuously between cluster nodes; a fast connection speeds between nodes helps with efficient synchronization.

Because the Coordination Service is I/O intensive, if you are running Tableau Server on computers that meet or just exceed the minimum hardware requirements, you may want to configure a Coordination Service ensemble that puts the service on nodes that are not being used for other server processes. This reduces the chance of delays due to I/O contention between server processes. For information on how to deploy an ensemble on dedicated Coordination Service-only nodes, see [Configure Tableau Server for High Availability with Coordination Service-Only Nodes](#).

The Coordination Service Quorum

To ensure that the Coordination Service can work properly, the service requires a *quorum*—a minimum number of instances of the service. This means that the number of nodes in your installation impacts how many instances of the Coordination Service you want to configure in your ensemble.

Number of Coordination Service instances to use

The maximum number of Coordination Service instances you can have in an ensemble on Tableau Server depends on how many Tableau Server nodes you have in your deployment. Configure a Coordination Service ensemble based on these guidelines:

Total number of server nodes	Recommended number of Coordination Service nodes in ensemble (must be 1, 3, or 5)	Notes
1-2 nodes	1 node	This is the default and requires no changes unless you want to move the Coordination Service off your initial node and onto your additional node.
3-4 nodes	3 nodes	
5 or more nodes	3 nodes or 5 nodes	<p>Five is the maximum number of Coordination Service instances you can install. A 3-node Coordination Service ensemble allows for one of the ensemble nodes to fail without causing Tableau Server to fail. A 5-node ensemble allows for two of the ensemble nodes to fail without causing Tableau Server to fail.</p> <p>For most installations, three Coordination Service nodes are adequate, and because of the I/O-intensive nature of the Coordination Service, this is the most performant configuration.</p> <p>If high availability is your absolute priority, you may want to consider deploying a 5-node Coordination Service ensemble. This provides the most redundancy in the event that one or more nodes fail but will require more system resources. A maximum of two of the ensemble nodes can fail without impacting Tableau Server (as long as any other services on the node also exist on still-functioning nodes).</p> <p>To reduce performance impact, locate the Coordination Service on nodes that are running fewer other</p>

Total number of server nodes	Recommended number of Coordination Service nodes in ensemble (must be 1, 3, or 5)	Notes
		services or consider using Coordination Service-only nodes. For details, see Configure Tableau Server for High Availability with Coordination Service-Only Nodes .

Deploy a new Coordination Service ensemble

If you install a total of three or more nodes, you should also deploy a Coordination Service ensemble. If you do not, you will get a warning message every time you make changes to the server configuration or topology. You can ignore this message, but as a best practice you should deploy a multi-node Coordination Service ensemble.

When you install Tableau Server, a single instance of the Coordination Service is installed on the initial node. TSM and Tableau Server depend on the Coordination Service to function properly, so to provide redundancy and ensure availability on multi-node installations, configure additional instances of the Coordination Service by deploying a Coordination Service ensemble. Coordination Service ensembles are installed with one, three, or five instances of the Coordination Service. In a three-node installation of Tableau Server, the recommended number of Coordination Service instances is three, one on each node.

Do not attempt to deploy a Coordination Service ensemble if there are other changes pending. Discard or apply any pending changes before deploying a new Coordination Service ensemble.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on

one of the nodes in your installation and TSM administrator credentials to run TSM commands.

The following steps illustrate how to deploy a new Coordination Service ensemble on an existing three-node Tableau Server cluster and clean up the old ensemble.

1. On the initial node, open a command prompt as administrator.
2. Stop Tableau Server:

```
tsm stop
```

If prompted, sign in as a TSM administrator.

Some TSM processes will continue to run, including the Administration Controller and Administration Agent.

3. Confirm there are no pending changes:

```
tsm pending-changes list
```

If there are pending changes, you need to either discard the changes or apply them.

Applying pending changes will take some time:

- Discard the changes

```
tsm pending-changes discard
```

or

- Apply the changes:

```
tsm pending-changes apply
```

Wait until the command completes and you are returned to the system prompt.

4. Get the node IDs for each node in the cluster:

```
tsm topology list-nodes -v
```

5. Use the `tsm topology deploy-coordination-service` command to add a new Coordination Service ensemble by adding the Coordination Service to specified nodes. You must specify the node(s) that the Coordination Service should be added to, using the actual node ID to identify each node. The command also makes the new ensemble the "production" ensemble (the ensemble in use) and removes the old ensemble, unless the deployment fails. If this happens, see step 6 below.

Note: A "y/n" prompt displays confirming that a server restart will take place. To run the command without input, include the `--ignore-prompt` option.

For example, deploy the Coordination Service to all three nodes of a three-node cluster, where the nodes are node1, node2, and node3:

```
tsm topology deploy-coordination-service -n node1,node2,node3
```

Wait until the command completes and you are returned to the system prompt.

6. (Optional) If the deployment fails, you need to run the `tsm topology cleanup-coordination-service` command to remove the unsuccessfully deployed ensemble. For details on running the command, see `tsm topology cleanup-coordination-service`.

7. Start Tableau Server:

```
tsm start
```

Configure Client File Service

The Client File Service (CFS) manages most shared files in a multinode cluster. For example, authentication related certificates, keys, and files (OpenID, mutual SSL, SAML, and Kerberos), and customization files are managed by CFS.

A single instance of CFS is configured on the initial node when you first install Tableau Services Manager (TSM) and Tableau Server. You can and should configure additional instances on other nodes.

In a cluster, if a node that is running your only instance of CFS fails, any files being managed by CFS will be lost, and you will need to repopulate CFS those files by reimporting certs and custom images, and making any related configuration changes. For a list of files managed by CFS, see [Tableau Server Client File Service](#).

Keep in mind these limitations and recommendations:

- There must be at least one instance of CFS for any Tableau Server installation. You cannot remove all instances of CFS.
- We recommend you do not configure more than one instance on any one node. Additional instances would not provide any benefit and would be a waste of resources.
- We recommend you configure a CFS instance on each node where you deploy the Coordination Service. This provides redundancy and helps safeguard Tableau Server from unexpected errors in case a node fails.

This article explains how to add or remove an instance of CFS. You cannot configure CFS from the Web UI. You must use the CLI to add or remove CFS. The procedure is the same one you use for adding a process to a node.

Configure CFS on additional nodes

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are adding CFS to:

```
tsm topology list-nodes -v
```

3. Add CFS on the node by specifying the node, the process, and a single instance.

For example, this command adds an instance of CFS to node2:

```
tsm topology set-process -n node2 -pr clientfileservice -c 1
```

If you attempt to add an instance of CFS to a node that already is configured with CFS, an error message will let you know there is already an instance on the node.

To add CFS to additional nodes, repeat this step for each node.

4. Apply the changes:

```
tsm pending-changes apply
```

Repository Failover

In a Tableau Server installation, the repository (pgsql) database is one of the key required processes. The Tableau Server repository stores information about Tableau Server users, groups and group assignments, permissions, projects, data sources, and extract metadata and refresh information. Because it is critical to the server functioning, Tableau Server has a built-in automatic "failover" for the repository when server is installed in a distributed environment that meets certain requirements.

Automatic repository failover

Automatic repository failover means that if there is a problem with the active Tableau Server repository, the server will automatically switch to using the passive repository. This does not happen immediately, to protect against ephemeral issues with the repository that don't justify a switch, but if the repository is unavailable for more than 1-5 minutes, failover occurs. For example, if the underlying PostgreSQL service fails, then failover will occur in about a minute. However other configuration problems may not trigger a failure for up to 5 minutes.

For automatic repository failover to work, your Tableau Server installation needs:

- A minimum of three nodes
- Two instances of the repository installed

Optional but highly recommended:

- A multi-node Coordination Service ensemble deployed

With these conditions satisfied, repository failover will occur if the active repository becomes unavailable, either due to a problem with the process, or a problem with the node the process is running on. If the original repository becomes available again (if, for example, the node is restarted and all processes come up properly), it is made the passive repository, available for failover if necessary.

Manual repository failover

There may be reasons you want to shift back to the original repository after failover occurs. One reason would be if that instance of the repository is installed on a computer with more resources. To do this, use the `tsm topology failover-repository` command to manually switch back to the original repository. For more information, see `tsm topology failover-repository`.

Preferred active repository

When you configure Tableau Server you have the option to specify a node as the preferred active repository. When Tableau Server is configured for repository failover, the preferred active repository node is the one used for the active repository. This is an optional step, and if you do not specify a preferred active repository node, Tableau Server will select the active repository node on startup.

To configure the preferred active repository, use the `tsm configuration set` command to configure the `pgsql.preferred_host` option:

```
tsm configuration set -k pgsql.preferred_host -v "<host_name>"
```

Note: The `host_name` is case-sensitive and must match the node name shown in the output of `tsm status -v`.

Configure a preferred active repository node if you want Tableau Server to select a specific node on startup. You might want to do this if you have a particular server you want to use for your active repository (a computer with more disk space or memory for example), or if you are

using custom administrative views. Custom administrative views have embedded connection information that refers to the repository for which you created the views. For more information on connecting to the Tableau Server repository, see [Collect Data with the Tableau Server Repository](#)

Recover from an Initial Node Failure

The first computer you install Tableau on, the "initial node," has some unique characteristics. Three processes run only on the initial node and cannot be moved to any other node except in a failure situation, the License Service (License Manager), Activation Service, and TSM Controller (Administration Controller). Tableau Server includes a script that automates moving these processes to one of your other existing nodes so you can get complete access back to TSM and keep Tableau Server running.

Two other processes are initially included on the initial node but can be added or moved to additional nodes, the CFS (Client File Service) and the Coordination Service. Depending on how your installation was configured with CFS and Coordination Service, you may also need to take steps to redeploy these.

If an initial node fails

If there is a problem with the initial node and you have redundant processes on your other nodes, there is no guarantee that Tableau Server will continue to run.

- Tableau Server can continue to run for up to 72 hours after an initial node failure, before the lack of the licensing service impacts other processes. If so, your users *may* be able to continue to sign in and see and use their content after the initial node fails, but you will not be able to reconfigure Tableau Server because you won't have access to the Administration Controller.
- If you are running a version of Tableau Server 2021.4.2 (or older) that is configured for ATR, then problems with the initial node will render all server functionality unavailable. This is true whether the node has a problem or if you intentionally stop it (for instance, to do a system-level patch).

Even when configured with redundant processes, *it is possible that Tableau Server may not continue to function after the initial node fails*. This is true even when an installation is configured for high availability. This means you should make a point of moving the two unique processes to another of your running nodes as soon as possible. If your initial node fails for reasons that are recoverable in a relatively short amount of time (for example, a hardware failure you can correct), you should first attempt to bring the node back up without using the procedure below.

Note: The steps in this article require server downtime and can be disruptive, and should only be used in the event of a catastrophic failure of the initial node. If you are unable to get your initial node running again, use the following steps to move key TSM processes to another node in your cluster.

General requirements

The 2021.1 version of Tableau Server has been updated with improved recovery functionality. The procedure in this topic has been written for Tableau Server 2021.1.

If you are attempting to recover a failed node from an earlier version of Tableau Server, you must follow the procedure for that version. To view archived versions of Tableau help, see [Tableau Help](#).

- As part of the process for setting up a multi-node Tableau Server installation you should have deployed a Coordination Service ensemble. The process below assumes there was a Coordination Ensemble deployed before there was a problem with the initial node. For more information about deploying a Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#).
- This process assumes that you have configured instances of Client File Service (CFS) on every node that is running the Coordination Service. If you did not add additional instances of CFS, your only instance was on the initial node, and you will need to add at least one instance of CFS to another node. You will also need to repopulate CFS. Tableau Server requires at least one instance of the CFS. For more information, see [Configure Client File Service](#) and [Tableau Server Client File Service](#).

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

Move the TSM Controller, License Service, and Activation Service to another node

If there is a problem with the initial node, the TSM Controller, the Licensing Service, and Activation Service need to be started on another node. Follow these steps to use the provided `move-tsm-controller` script and get the TSM Controller, Licensing Service, and Activation Service working on another node.

1. On a node that is still working, run the Controller recovery script. To do this, open a command prompt, navigate to the Tableau Server script directory (By default: `C:\Program Files\Tableau\Tableau Server\packages\scripts.<version_code>\`), and type the following command:

```
move-tsm-controller -n <nodeID>
```

where "nodeID" is the ID for the node you want the TSM Controller to run on. For example:

```
move-tsm-controller -n node2
```

2. Close and reopen the command window and verify the Administration Controller is running on the node by typing this command:

```
tsm status -v
```

3. Stop Tableau Server.

Tableau Server on Windows Help

The remainder of this procedure includes some commands with the `--ignore-node-status` option. When a command is run with the `--ignore-node-status` option, the command will run without consideration of the status of the specified node. To use `--ignore-node-status`, specify the failed node:

```
tsm stop --ignore-node-status <nodeID>
```

For example, if node1 has failed, run the command as follows:

```
tsm stop --ignore-node-status node1
```

4. Add the License Service to the node:

```
tsm topology set-process -pr licenseservice -n <nodeID> -c 1
```

5. Remove the old License Service from the original node, where "nodeID" is the initial node that has failed:

```
tsm topology set-process -pr licenseservice -n <nodeID> -c 0
```

6. If you're using Server ATR, add the Activation Service to the node:

```
tsm topology set-process -pr activationsservice -n <nodeID> -c 1
```

7. If you're using Server ATR, remove the old Activation Service from the original node, where "nodeID" is the initial node that has failed:

```
tsm topology set-process -pr activationsservice -n <nodeID> -c 0
```

Important: In a cluster, if a node that is running your only instance of CFS fails, any files being managed by CFS will be lost, and you will need to repopulate CFS those files by reimporting certs and custom images, and making any related configuration changes. For a list of files managed by CFS, see Tableau Server Client File Service.

8. If the initial node had been running the Messaging Service, add the Messaging Service to this node:

```
tsm topology set-process -pr activemqserver -n node2 -c 1
```

9. (Optional) You can also add other processes that had been running on the initial node but are not running on this node. For example, to add an cache server:

```
tsm topology set-process -pr cacheserver -n node2 -c 1
```

10. Apply the changes:

```
tsm pending-changes apply --ignore-node-status <nodeID>
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

11. Restart the TSM Administration Controller:

```
net stop tabadmincontroller_0
```

```
net start tabadmincontroller_0
```

Note: You must run these commands as an administrator from a command prompt. Depending on how your computer is configured, you may need to run them in the `C:\Windows\System32` folder.

Note: It may take a few minutes for `tabadmincontroller` to restart. If you attempt to apply pending changes in the next step before the controller has fully restarted,

TSM will not be able to connect to the controller. You can verify that the controller is running by using the `tsm status -v` command. Tableau Server Administration Controller should be listed as "is running".

12. Apply pending changes (there may not appear to be any, but this step is required):

```
tsm pending-changes apply --ignore-node-status <nodeID>
```

13. Activate the Tableau Server license on the new Controller node:

```
tsm licenses activate -k <product-key>
```

14. Verify the license is properly activated:

```
tsm licenses list
```

15. If the initial node was running the Coordination Service, you need to deploy a new Coordination Service ensemble that does not include that node. If you have a three node cluster and the initial node was running the Coordination Service, you must deploy a new, single-instance Coordination Service ensemble on a different node and clean up the old ensemble. In this example, a single instance of the Coordination Service is being deployed to the second node:

```
tsm topology deploy-coordination-service -n node2 --ignore-  
node-status node1
```

16. If the initial node was running a File Store instance, you need to remove that instance:

```
tsm topology filestore decommission -n <nodeID> --delete-  
filestore
```

Where `nodeID` is the initial node that has failed.

17. Apply pending changes, using the `--ignore-warnings` flag if the new Coordination Service ensemble you deployed above is a single node ensemble:

```
tsm pending-changes apply --ignore-node-status node1 --ignore-warnings
```

18. Remove the initial node, where `nodeID` is the initial node that has failed:

```
tsm topology remove-nodes -n <nodeID>
```

19. Apply pending changes, using the `--ignore-warnings` flag if the new Coordination Service ensemble you deployed above is a single node ensemble:

```
tsm pending-changes apply --ignore-warnings
```

20. Start Tableau Server:

```
tsm start
```

At this point your server should start, and you will be able to use TSM to configure it.

The next step is to replace your initial node so your cluster has the original number of nodes. How you do this depends on whether or not you want to reuse the node that failed. We recommend that you only reuse that node if you are able to identify the reason it failed, and take steps to keep the failure from recurring.

21. If you plan to reuse the original node, you first need to completely remove Tableau from it. Do this by running the `tableau-server-obliterate` script. For details on doing this, see [Remove Tableau Server from Your Computer](#).
22. On a fresh computer, or on your original computer after completely removing Tableau, install Tableau using your original Setup program and a bootstrap file generated from the node that is now running the Administration Controller and Licensing Service. This creates an additional node you can configure as part of your cluster. For details on how to add the node, see [Install and Configure Additional Nodes](#).

A best practice is to configure any processes you lost when the original node failed, to make sure your cluster is fully redundant. You may want to move processes from your new initial node to the newly added additional node to duplicate your original configuration. For example, if your initial node was only running gateway and File Store, you may want to configure the new initial node the same way.

23. You should also redeploy a new Coordination Service ensemble, once you have your nodes up and running the way you want. For details, see [Deploy a Coordination Service Ensemble](#) .
24. Finally, if you have not already done this, add an instance of CFS to every node that is running the Coordination Service. For more information, see [Configure Client File Service](#)

In a cluster, if a node that is running your only instance of CFS fails, any files being managed by CFS will be lost, and you will need to repopulate CFS those files by reimporting certs and custom images, and making any related configuration changes. For a list of files managed by CFS, see [Tableau Server Client File Service](#).

Recover from a Node Failure

If there is a problem with one of your server nodes, and you have redundant processes on your other nodes, Tableau Server can continue to run. Your users can continue to sign in and see and use their content after the node fails, but they may experience performance degradation as a result of the failed node. In addition, your server will be at greater risk of catastrophic failure if the bad node was running processes that are no longer redundant. This means you should make a point of removing the bad node and replacing it as soon as you can. If your node fails for reasons that are recoverable in a relatively short amount of time (for example, a hardware failure you can correct), you should first attempt to bring the node back up without using the procedure below.

Note: If the failed node is your *initial* node, there are larger implications for your Tableau Server installations. For details on how to recover from the failure of an initial node, see [Recover from an Initial Node Failure](#).

General requirements

The 2020.1 version of Tableau Server has been updated with improved recovery functionality. The procedure in this topic has been written for Tableau Server 2020.1.

If you are attempting to recover a failed node from an earlier version of Tableau Server, you must follow the procedure for that version. To view archived versions of Tableau help, see [Tableau Help](#).

- There is at least one functioning node with an instance of the File Store on it.
- There is at least one functioning node with a Repository on it.
- There is at least one functioning node with the Client File Service (CFS) on it.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

Removing a Failed Node

To remove a failed node from a Tableau Server cluster:

1. Identify the failed node:

```
tsm status -v
```

The failed node will have a status of "ERROR" and processes will show as unavailable.

The node ID is listed as "node<n>" with the machine name following it. For example, node3:

Tableau Server on Windows Help

```
node3: WIN-00915SFASVH
```

```
Status: ERROR
```

```
'Tableau Server Gateway 0' status is un
```

2. Stop Tableau Server.

The remainder of this procedure includes some commands with the `--ignore-node-status` option. When a command is run with the `--ignore-node-status` option, the command will run without consideration of the status of the specified node. To use `--ignore-node-status`, specify the failed node:

```
tsm stop --ignore-node-status <nodeID>
```

For example, if node3 has failed, run the command as follows:

```
tsm stop --ignore-node-status node3
```

3. Determine any key processes that were running on the node:

- If the failed node was running the Messaging Service, you need to remove the service from the failed node and add it to a working node.

Remove it from the failed node:

```
tsm topology set-process -pr activemqserver -n <nodeID> -c  
0
```

Add it to a working node:

```
tsm topology set-process -pr activemqserver -n <nodeID> -c  
1
```

- If the failed node was running the Coordination Service, you need to deploy a new ensemble before you can remove the node:

```
tsm topology deploy-coordination-service -n <good_nodeID> -  
-ignore-node-status <failed_nodeID>
```

- If the failed node was running the only instance of Client File Service (CFS), you need to configure a new instance of CFS on a working node. We recommend that you configure CFS on every node that is running the Coordination Service. For detail steps, see [Configure Client File Service](#).
- If the failed node was running File Store, you need to force-decommission File Store and remove it before you can remove the node.

```
tsm topology filestore decommission -n <nodeID> --delete-  
filestore
```

Apply pending changes (use `--ignore-warnings` option if you had a three node cluster and a single Coordination Service instance):

```
tsm pending-changes apply --ignore-warnings --ignore-node-  
status <nodeID>
```

4. If the cluster was a three-node cluster and there are repositories on the remaining working nodes, you need to either remove one repository, or add a new node. This is because you are limited to a single instance of the repository when you have fewer than three nodes.

To remove one repository:

```
tsm topology set-process -n <nodeID> -pr pgsql -c 0
```

5. Run the command to remove the failed node. This adds the change to the pending changes list:

```
tsm topology remove-nodes -n <nodeID>
```

6. Verify the node removal is pending:

```
tsm pending-changes list
```

7. Apply pending changes to remove the node:

```
tsm pending-changes apply
```

8. Start Tableau Server:

```
tsm start
```

9. Install Tableau Server on a new node and configure the node with the processes that the old, failed node had been running.
10. On a fresh computer, or on your original computer after completely removing Tableau, install Tableau using your original Setup program and a bootstrap file generated from the initial node. For details on how to do this, see [Install and Configure Additional Nodes](#).

A best practice is to configure any processes you lost when the original node failed, to make sure your cluster is fully redundant.

11. You should also redeploy a new Coordination Service ensemble, once you have your nodes up and running the way you want. For details, see [Deploy a Coordination Service Ensemble](#).
12. Finally, if you have not already done this, add an instance of CFS to every node that is running the Coordination Service. For more information, see [Configure Client File Service](#).

Configure Nodes

Use the Tableau Services Manager (TSM) Web UI or CLI commands to configure the topology of a node. The initial node is configured with a default that includes all the processes used by TSM and Tableau Server. When you add additional nodes you need to specify which processes will run on those nodes, and how many instances of those processes will run. You may also want to change the topology of the initial node, either adding instances of existing processes, or moving some of those processes to your additional nodes (this is common when setting up a distributed installation of Tableau Server).

Note: You cannot remove the File Store or Repository (pgsql) if this is the only instance of that process in your cluster. You must have at least one instance of each of the processes in your Tableau Server installation, and you must add the second instance and allow it to synchronize with the first before you remove the process on the original node. For more information see [Move the Repository Process](#) and [Move the File Store Process](#).

Note: If you have Tableau Resource Monitoring Tool Agent installed on this node, you will need to update the Resource Monitoring Tool Master Server to reflect the changes you make to a Tableau Server node. Changes include adding or removing processes, or changing the number of processes on a node. For more information, see [Tableau Server Topology Changes](#).

Use the TSM web interface

In most cases, you can make multiple changes to your server configuration. Exceptions are if you are moving or removing a File Store instance or the Repository.

To configure your Tableau Server nodes using the TSM web interface, do the following:

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab.

Your next steps depend on the configuration changes you want to make.

- **Add processes**—Add processes to a node by specifying the number of instances you want on the node, or selecting the box for the process.

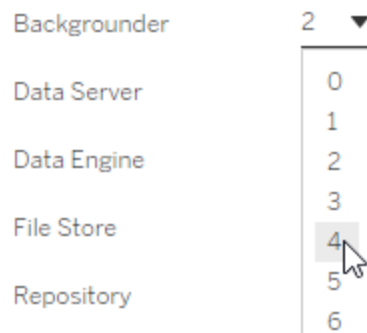

Tableau Server on Windows Help

For example, to add four instances of the Backgrounder and a Gateway to a node:

- a. Select the **Gateway** box:

- b. Set the **Backgrounder** count to 4:

Adding Backgrounder to a node will also add an instance of Data Engine if one is not already on the node.

Note: The TSM Web UI limits you to a maximum of 8 instances of processes that allow you to select the number of instances. To configure more instances than this, use the command line and the `TSM topology set-process` command. For more information, see `tsm topology set-process`.

- **Change process count**—Change the number of processes on a node by specifying the new number, or selecting the box for the process.
- **Remove a process completely**—Remove all instances of a process from a node by clearing the box for the process, or setting the count to 0 (zero).

In most cases you move a process from one node to another by setting the process instance count on the first node to 0 (zero), and setting the count to a non-zero value on the second node.

If you are attempting to make a configuration that is not allowed (if, for example, you try to remove a File Store that has not been decommissioned), a message displays to let you know this.

3. Click **Pending Changes** at the top right, and **Apply Changes and Restart** to commit the changes and restart Tableau Server.

Use the TSM CLI

- Adding processes to a node
- Changing the number of processes on a node
- Removing all instances of a process from a node
- Moving all instances of a process from one node to another node

To configure nodes, run commands from the initial node and use the node ID to specify which node you are configuring. To determine the node ID, use the `tsm topology list-nodes` command. Use the `tsm topology set-process` command to add, update or remove a process on a node. You need to specify the node you are configuring, the process you are adding, updating, or removing, and the number of instances of the process. After setting the topology for a node you need to apply the changes to Tableau Server.

Apply changes using the `tsm pending-changes apply` command. After the changes are applied, Tableau Server is returned to the state it was in before the command was run. This means that if it was running, it will be restarted, and if it was stopped it will remain stopped after pending changes have been applied. In most cases, if Tableau Server is running when you apply pending changes, the server is stopped so that changes can be applied, and then restarted. The exception is if you are changing the number of instances of Backgrounder, or VizQL Server on an existing node. With changes to those processes on an existing node, Tableau Server does not have to be stopped if it is running.

You need the node ID for a node in order to configure the node. To determine the node ID, use this command:

```
tsm topology list-nodes -v
```

Note: Examples here show some process names. For a complete list, see [Tableau Server Processes](#).

Adding processes to a node

Use the `tsm topology set-process` command to add a process to a node. You need to specify the node you are configuring, the process you are adding, and the number of instances of the process.

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are changing:

```
tsm topology list-nodes -v
```

3. Add processes on the node by specifying the process and the number of instances.

For example, this command adds two instances of backgrounder to node1:

```
tsm topology set-process -n node1 -pr backgrounder -c 2
```

4. Apply the changes:

```
tsm pending-changes apply
```

Changing the number of processes on a node

Change the number of processes on a node by specifying an already configured process and providing a new value for the number of instances.

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are changing:

```
tsm topology list-nodes -v
```

3. Change the number of processes on the node by specifying an already configured process and providing a new value for the number of instances.

For example, on a node (node1) that is already running backgrounder, this command changes the number of instances to four:

```
tsm topology set-process -n node1 -pr backgrounder -c 4
```

4. Apply the changes:

```
tsm pending-changes apply
```

Removing all instances of a process from a node

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are changing:

```
tsm topology list-nodes -v
```

3. Remove a process from a node by specifying a count of 0 instances for that process on the node.

For example, this command removes the backgrounder process from node1:

```
tsm topology set-process -n node1 -pr backgrounder -c 0
```

4. Apply the changes:

```
tsm pending-changes apply
```

Moving all instances of a process from one node to another node

In most cases you move a process from one node to another by setting the process instance count on the first node to zero, and setting the count to a non-zero value on the second node.

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are changing:

```
tsm topology list-nodes -v
```

3. Move a process from one node to another node by specifying a count of 0 instances for that process on the first node and specifying a count of 1 or greater to the second node.

For example, these commands remove Backgrounder from node0 and add two instances of it to node1:

```
tsm topology set-process -n node0 -pr backgrounder -c 0
```

```
tsm topology set-process -n node1 -pr backgrounder -c 2
```

4. Apply the changes:

```
tsm pending-changes apply
```

Workload Management through Node Roles

Using node roles, you can configure where certain types of workloads are processed on your Tableau Server installation. The node roles features allows you to dedicate and scale resources to specific workloads. You can configure node roles for Backgrounder and File Store.

The Backgrounder node role specifies the type of background tasks that should run on a node, whereas the File Store node role specifies the type extract workload that should run on a node. Both node roles are specified at a node level. Although these node roles can work independently to optimize selected workload, the two node roles in combination can be used to specialize server nodes to preferentially execute selected workloads to optimize performance extract heavy workloads. This combination is discussed in more detail later in the File Store node roles section.

Backgrounder node roles

The Backgrounder process runs Tableau Server tasks, including extract refreshes, subscriptions, flow tasks, 'Run Now' tasks, and tasks initiated from *tabcmd*. Running all these tasks can use a lot of machine resources. If you have more than one Backgrounder node in your cluster, you can manage your Backgrounder workload by specifying the type of tasks a Backgrounder can run on a node using the Backgrounder node role feature.

This configuration option is currently available only through TSM CLI commands and is only useful on multi-node clusters. If you have only one node, the Backgrounder is set to run all tasks by default and that cannot be changed.

Using Backgrounder node roles

The Backgrounder node role feature is intended to give you more control and governance over where certain type of Backgrounder workloads are processed in your Tableau Server installation and allows you to dedicate and scale resources to specific workloads.

For example, if your deployment is heavy on extract and users are running a lot of extract refreshes or encryption jobs, it could be beneficial to dedicate a node to extract refreshes. Similarly, in the case of subscriptions, if your Tableau Server installation processes a lot of subscriptions and you want to ensure that other jobs do not take resources from subscriptions, then you can dedicate a node to subscriptions. In these cases, you would also want to dedicate other backgrounder nodes to workloads other than extract refreshes or subscriptions.

Tableau Server on Windows Help

To support high availability, Tableau recommends having multiple nodes that are dedicated towards a specific workload. For example, if you dedicate a node to extract refreshes, you should also configure a second node to process extract refresh workload. This way if a node dedicated to extract refreshes becomes unavailable, extract refreshes can still be processed by the other node.

Configuration options

Configuration	Jobs
all-jobs (default)	All Tableau Server jobs
flows	Flow run jobs.
no-flows	All jobs except flows.
extract-refreshes	Jobs that are created for: Incremental refreshes, full refreshes, encryption and decryption of all extracts including extracts that flow outputs create.
subscriptions	Subscription jobs
system	System maintenance jobs that interact with other Tableau Server processes. For example, cleaning crashed jobs, reaping database events, and synching Active Directory.
extract-refreshes-and-subscriptions	Extract-refreshes, encryption and decryption of all extracts including extracts that flow outputs generate, and subscription jobs.
no-extract-refreshes	All jobs except extract-refreshes, extract encryption and decryption of all extracts including extracts created from flow outputs.
no-subscriptions	All jobs except subscriptions.
no-extract-refreshes-and-subscriptions	All jobs except extract-refreshes, encryption and decryption of all extracts including extracts created from flow outputs, and subscriptions.

no-system	All jobs except system maintenance jobs.
-----------	--

For more information on how to use the tsm commands to set the node role, see [tsm topology](#).

Note: Making configurations to node roles require a restart of the server and will require some downtime. For more information, see [tsm pending-changes](#).

License requirements

Configuring a node to do only a specific type of tasks, like, flows, extract refreshes, and subscriptions, you must have one of the following licenses activated on your Tableau Server:

- To configure a node to run flows, you must have a valid Data Management license activated on your server, and have Tableau Prep Conductor running on that node. To learn more about Tableau Prep Conductor, see [Tableau Prep Conductor](#).
- To configure a node to run extract refreshes, subscriptions, and any combination related to extract refreshes and subscriptions you must have a valid Advanced Management license activated on your Tableau Server. If the license expires or is deactivated, you will see an error any time you make a change to the Server configuration. For more information on Advanced Management, see [About Tableau Advanced Management on Tableau Server](#).

Important!

While flows, extract refreshes, and subscriptions can be expensive and resource heavy, they are not the only jobs that may require dedicated resources. In the **all jobs** group, there are a variety of System jobs that the Backgrounder executes, such as thumbnail generation for workbooks. Make sure that the nodes that run jobs other than extract refreshes, subscriptions, or flows have enough machine resources.

For more information on configuring node roles using TSM commands, see [tsm topology set-node-role](#).

Considerations

There are some rules you must consider when configuring Backgrounder node roles, which are listed below:

- Only one node role configuration can be set for a node at a time. You cannot configure multiple node roles on a node.
- To configure a node role, there must be at least one Backgrounder process on that node.
- If you have only one Backgrounder node, you must configure this node to run all jobs. This is the default configuration and does not require additional licensing.
- If you have more than one Backgrounder node, combined, they must be configured to handle all jobs. This can be achieved in the following ways:
 - Configure one of the nodes to run all jobs using the all jobs option. This is the easiest and most straightforward way.
 - Using one of the exception configurations on one of the nodes:
 - no-flows
 - no-subscriptions
 - no-extract-refreshes
 - no-extract-refreshes-and-subscriptions

For example, in a cluster where there are three backgrounders, you could have one node configured to run flows, one to run subscriptions and extract refreshes, and one to run all jobs except flows, subscription and extract refreshes.

Note: The ability to specify node roles to run flows, or run all jobs except flows, or run all jobs was introduced in 2019.1.

File Store node roles

The Tableau Server File Store controls the storage of extracts. There are three broad categories of workloads that are extract dependent.

Extract Workload	Execution Service
Refresh	Backgrounder
Query	Data Engine
Backup/Restore	Backup/Restore

File Store node role management in combination with Backgrounder node role management gives server admins the ability to specialize server nodes to preferentially execute selected workloads to optimize performance of all categories of extract heavy workloads.

It is possible to specialize a node to execute extract query workloads through a topology that has only stand-alone Data Engine nodes. For more information, see [Optimize for Extract Query-Heavy Environments](#). However, this is at the expense of extract refresh workloads, which are executed by Backgrounder nodes. With the topology-based isolation approach, extract refresh heavy Backgrounder workloads can get slower as none of the Backgrounder nodes have a File Store and thus all extract refresh traffic goes over the network.

With the File Store Node Role configuration option, it is possible to designate certain server nodes that process extract queries to be preferentially selected from the list of server nodes that can do so. This helps speed up workloads such as backup and extract refreshes by allowing server admins to enable File Store on Backgrounder server nodes, which prevents extract queries from running on these nodes. This feature is useful if you have an extract-heavy query workload and an extract-heavy refresh workload and want to achieve optimal extract query and refresh performance.

Guidelines to optimize for extract refresh and backup or restore workloads.

Start from a topology with specialized Data Engine nodes (see Optimize for Extract Query-Heavy Environments).

Process	Initial Node	Additional Node 1	Additional Node 2	Additional Node 3
Cluster Controller	✓	✓	✓	✓
Gateway	✓	✓		
Application Server	✓	✓		
VizQL Server	✓ ✓	✓ ✓		
Cache Server	✓ ✓	✓ ✓		
Search & Browse	✓	✓		
Backgrounder	✓ ✓ ✓ ✓	✓ ✓ ✓ ✓		
Data Server	✓ ✓	✓ ✓		
Data Engine	✓	✓	✓	✓
File Store			✓	✓
Repository	✓	✓		

Topology 1 - Dedicated Data Engine Nodes

1. Add File Store to Node 0.

```
tsm topology set-process -n node0 -pr filestore -c 1
```

2. Designate Node 2 and Node 3 to preferentially execute extract-query workloads

```
tsm topology set-node-role -n node2, node3 -r extract-queries
```

3. Designate Node 0 to preferentially execute extract-refresh workloads.

```
tsm topology set-node-role -n node0 -r extract-refreshes
```

4. Designate Node 1 to preferentially execute non-extract-refresh workloads.

```
tsm topology set-node-role -n node1 -r no-extract-refreshes
```

5. Apply pending changes.

```
tsm pending-changes apply
```

Process	Initial Node	Additional Node 1	Additional Node 2	Additional Node 3
Cluster Controller	✓	✓	✓	✓
Gateway	✓	✓		
Application Server	✓	✓		
VizQL Server	✓ ✓	✓ ✓		
Cache Server	✓ ✓	✓ ✓		
Search & Browse	✓	✓		
Backgrounder	✓ ✓ ✓ ✓	✓ ✓ ✓ ✓		
Data Server	✓ ✓	✓ ✓		
Data Engine	✓	✓	✓	✓
File Store	✓		✓	✓
Repository	✓	✓		

Topology 2 - Extra File Store Node

Note: In your Tableau Server deployment, adding File Store roles to existing nodes will temporarily increase network I/O between all File Store nodes while the new File Store is being synchronized. The duration of this operation is dependent on the volume of data on the File Store and the network bandwidth capacity. The status of synchronization can be monitored using the TSM Web GUI. If you are adding more than one File Store to your deployment, it is recommended to add them consecutively and wait for the initial synchronization to complete in between each File Store addition.

Fine tune extract query workload management

When extract queries for email subscriptions and metric alerts are running at the same time that users are interactively viewing extract-based visualizations, users may experience slower than normal viz load times. Use the following node roles to fine tune how these workloads are prioritized.

Node role to use	Type of extract query workload	Example
extract-queries	scheduled	email subscriptions and metric alerts

<code>extract-queries-interactive</code>	<code>interactive</code>	users viewing an extract-based visualization
--	--------------------------	--

If your server deployment is seeing growth in email subscriptions and metric alerts, you can add nodes and assign the `extract-queries` node role, which makes them more available to handle subscriptions and alerts.

If your server deployment is seeing growth in users viewing extract-based visualizations, you can add nodes and assign the `extract-queries-interactive` node role, which makes them prioritize interactive extract queries to reduce extract-based viz load times. The `extract-queries-interactive` node role is a preference and not strict isolation. This means that queries will be routed to nodes that have the `extract-queries-interactive` node role assigned. If you have multiple nodes with the `extract-queries-interactive` role, queries will be routed based on node health.

For example, add a node and designate it to preferentially execute `extract-queries-interactive` workloads.

- `tsm topology set-node-role -n node4 -r extract-queries-interactive`

Configuration options

Configuration	Jobs
all-jobs (default)	All Tableau Server jobs
extract-queries	Jobs that are created for extract queries. The nodes selected will run as all-jobs and will prioritize the processing of extract queries.
extract-queries-interactive	Jobs that are created for extract queries. The nodes selected will run as all-jobs and will prioritize the processing of interactive extract queries, such as those that run when a user is looking at their screen and waiting for an extract-based dashboard to load. This is an advanced setting and it should only be used if the cluster has a heavy subscription and alert job workload that causes users to experience degraded per-

	formance on viz load times that run around the same time as scheduled loads.
--	--

For more information on configuring node roles using TSM commands, see `tsm topology set-node-role`.

License requirements

To configure a node to run extract queries you must have a valid Advanced Management license activated on your Tableau Server.

How to see node roles

Use the following command to see what node roles are currently configured on Tableau Server:

```
tsm topology list-nodes -v
```

Who can do this

Tableau Server Administrators can configure node roles and activate any required product keys.

Install Tableau Server on a Two-Node Cluster

When you install Tableau Server on a two-node cluster, you can install server processes on one or both nodes. A two-node cluster can improve the performance of Tableau Server, because the work is spread across multiple machines.

Note the following about two-node clusters:

- A two-node cluster does not provide failover or support for high availability.
- You can't install more than one instance of the repository on a two-node cluster, and the repository must be on the initial node.

If you need failover or high availability, or want a second instance of the repository, you must install Tableau Server on a cluster of at least three computers. In a cluster that includes at least three nodes, you can configure two instances of the repository, which gives your cluster fail-over capability.

Restart Multi-Node Tableau Server Computers

Restarting the computers running a multi-node installation of Tableau Server requires that you follow a few specific steps.

To restart computers running a multi-node installation of Tableau Server:

1. Stop Tableau Server. To do this:
 - a. On the initial node, open a command prompt as administrator.
 - b. Run this tsm command:

```
tsm stop
```
 - c. Wait until Tableau Server is stopped.
2. Restart the additional node computers. These are all the other computers *except* for the one running TSM Controller.
3. Wait until each of the additional node computers has completely restarted, including the Tableau Services Manager (TSM) processes installed there.
4. Restart the initial node computer (the computer running TSM Controller). When it has completely restarted and Tableau Server is running, connections to each additional node should be restored.

Maintain a Distributed Environment

After you set up an initial node and one or more additional nodes for a distributed installation, you can perform all subsequent configuration and updates from the initial node, using the TSM CLI, or from any computer using a browser and the TSM Web interface.

When you install additional nodes, they are added by computer name. If the computer name of a node changes, you will need to remove and reinstall the node. For details on removing a node, see [Remove a Node](#).

You can monitor the status of the Tableau Server cluster on the TSM Status page. See [View Server Process Status](#) for details.

Additional actions you may need to maintain your distributed environment include:

Move the Repository Process

Tableau Server relies on the PostgreSQL repository to store server data. There must always be at least one active instance of the repository in any Tableau Server installation, and you can have a maximum of two instances (one active, one passive) if you have at least three nodes in your installation. You cannot remove a repository instance if it is the only instance.

This means that if you want to move the only instance of your repository from one node to another node, you need to add a second instance and synchronize the new repository with the old one before you remove the old one. Synchronize repository instances by starting server. If you've added a new repository, it will automatically synchronize with the existing instance.

If you are deleting a node from your server cluster and that node is hosting the only instance of the repository, you must add a second instance of the repository and synchronize the instances before removing the node.

If you are also moving the file store, you can move the repository at the same time. See [Move the File Store Process](#).

Before making a change to the repository, create a full backup of Tableau Server. For more information, see [tsm maintenance backup](#).

Important: You cannot add a second repository instance and remove the first one in the same step. You must have both running so the contents of the first is synchronized with the second, before you remove the original instance.

The steps for moving the repository are:

1. Add a new instance of the repository to another node, start server, and wait for it to synchronize with the first repository.
2. Remove the instance of the repository from the original node.

Use the TSM web interface

To move a repository you need to first add a second instance on a second node, and then after the two instances have synchronized all the data in the original repository, remove the original instance. These steps must be done separately to allow for the synchronization of content between the two instances.

Add a new instance of the repository.

1. Open TSM in a browser:

```
https://<tsm-computer-name>:8850
```

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab.
3. For the node you are adding the repository to:

Select **Repository** (pgsql).
4. Click **Pending Changes** at the top of the page:

The Pending Changes list displays.

If you are configuring a three- or five-node cluster and have not deployed a Coordination Service ensemble, a warning will display. You can continue, and deploy a Coordination Service ensemble in a separate step. For details on deploying a Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#).

5. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.
6. After Tableau Server has restarted, on the **Status** tab, verify that all processes are active.

Remove an instance of the repository.

1. In TSM, on the **Status** tab, verify that all processes are active. When both repositories show as Active, you can remove the first one.
2. Click the **Configuration** tab.
3. For the node you're removing the repository from, clear the **Repository** box.
4. Click **Pending Changes** at the top of the page.

If you are configuring a three- or five-node cluster and have not deployed a Coordination Service ensemble, a warning will display. You can continue, and deploy a Coordination Service ensemble in a separate step. For details on deploying a Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#).

5. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

Use the TSM CLI

To move a repository you need to first add a second instance on a second node, and then after the two instances have synchronized all the data in the original repository, remove the original instance. These steps must be done separately to allow for the synchronization of content between the two instances.

Add a new instance of the repository.

1. Add the repository (pgsql) to another node:

```
tsm topology set-process -n <nodeID> -pr pgsql -c 1
```

2. Apply the changes. If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

```
tsm pending-changes apply
```

3. Wait for the new repository on the second node to synchronize with the repository on the first node.

```
tsm status -v
```

Wait until the new repository status shows as "passive".

Remove an instance of the repository.

Once the new instance of the repository is fully synchronized and shows as "passive" you can remove the original instance:

1. Remove the repository from the first node by setting the process count to 0 (zero):

```
tsm topology set-process -n <nodeID> -pr pgsql -c 0
```

2. Apply the change. If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

```
tsm pending-changes apply
```

Move the File Store Process

This topic describes File Store process when configured to run locally on Tableau Server. However, File Store can be run locally as well as external to Tableau Server. For more information on Tableau Server External File Store, see [Tableau Server External File Store](#).

You cannot remove an instance of File Store if it is the only instance on the server. You cannot run Tableau Server without at least one instance of File Store. This means if you need to move the File Store, or if you are deleting a server node that is hosting the only instance of the File Store, you must first move File Store to another node.

Moving the File Store is a two-part process:

- Adding a second instance of File Store (if there is not an existing second instance).
- Decommissioning and removing the original instance of File Store.

This article assumes you have installed Tableau Server on an initial node and at least one additional node. For more information on adding nodes to Tableau Server, see [Install and Configure Additional Nodes](#).

Use the TSM web interface

Adding a second instance of File Store

This procedure assumes you have added an additional node. For more information on adding nodes to Tableau Server, see [Install and Configure Additional Nodes](#).

Tableau Server on Windows Help

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab.
3. For the node you want to add an instance of File Store on, select **File Store**.

Adding File Store to a node will also add an instance of Data Engine if one is not already on the node.

4. Click **Pending Changes** at the top of the page:

The Pending Changes list displays.

A Coordination Service ensemble warning displays because you are configuring a three-node cluster. You can continue. You will deploy a Coordination Service ensemble in an upcoming step.

5. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

Decommissioning and removing an instance of file store

1. In TSM, on the **Status** tab, verify that all processes are active.
2. Click the **Configuration** tab.
3. For the node you're removing File Store from, clear the **File Store** box.

This will generate a warning about decommissioning the File Store before removing it. You cannot remove an instance of File Store unless it has been decommissioned. Click **OK** to decommission and remove the file store. Data Engine will also be removed

unless an instance of one of these processes is installed on the node: VizQL Server, Application Server (Vizportal), Data Server, or Backgrounder.

4. If you are removing File Store from a node that also has the TSM Administrative Controller (usually the initial node), a warning will caution you about impact to server backup performance.

Click **Continue** to decommission File Store.

5. Click the **Status** tab to see the status of the decommission. When the instance of File Store is marked "Ready for removal" you can continue.

File Store	 Ready for removal		
------------	---	---	---

6. Click **Pending Changes** at the top of the page.

Note: If you are configuring a three- or five-node cluster, a Coordination Service ensemble warning will display. You can continue to apply pending changes and deploy a Coordination Service ensemble in a separate step. For information on deploying a Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#).

7. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

Use the TSM CLI

Adding a second instance of file store

1. Create a full backup of Tableau Server. For more information, see [Back up Tableau Server Data](#).
2. Add the File Store to a second node.

```
tsm topology set-process -n <nodeID> -pr filestore -c 1
```

Tableau Server on Windows Help

The File Store is automatically added. Data engine is also added if it is not already on the node.

Apply the configuration changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

3. Check the status of the new file store instance.

```
tsm status -v
```

Wait for the new File Store to synchronize with the File Store on the first node. When synchronization is complete the new File Store has a status of "running" instead of "synchronizing".

Decommissioning and removing an instance of File Store

Once you have a second instance of File Store installed and synchronized you can decommission and remove the original instance. You must decommission the original instance before you remove it. Doing this guarantees that any unique files on the File Store node are duplicated to another file store node.

1. Decommission the original File Store:

```
tsm topology filestore decommission -n <nodeID> --override
```

2. When the decommission command completes, remove the File Store from the node by applying the pending configuration changes. The File Store is automatically removed. Data Engine is also removed unless an instance of one of these processes is installed

on the node: VizQL Server, Application Server (Vizportal), Data Server, or Background.

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Move the Messaging Service Process

This article assumes you have installed Tableau Server on an initial node and at least one additional node. For more information on adding nodes to Tableau Server, see [Install and Configure Additional Nodes](#).

You cannot remove an instance of the Messaging Service if it is the only instance on the server. You cannot run Tableau Server without one instance of the Messaging Service. This means if you need to move the Messaging Service, or if you are deleting a server node that is hosting the Messaging Service, you must first move the service to another node.

Moving the Messaging Service is straightforward process of three steps:

- Remove the original instance of the Messaging Service.
- Add a new instance of the Messaging Service.
- Apply the pending changes.

Use the TSM web interface

Moving the Messaging Service

1. In TSM, on the **Status** tab, verify that all processes are active.
2. Click the **Configuration** tab.

3. For the node you're removing the Messaging Service from, clear the **Messaging Service** box.

This will activate the **Pending Changes** button, but in Pending Changes an error will tell you that the Messaging Service (activemqserver) is not on any node. Until you add it to another node, you cannot apply pending changes.

4. For the node you are adding the Messaging Service to, select the **Messaging Service** box.
5. Click **Pending Changes** at the top of the page.
6. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

Use the TSM CLI

Moving the Messaging Service

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the nodes you are changing:

```
tsm topology list-nodes -v
```

3. Remove the Messaging Service from one node:

```
tsm topology set-process -n <nodeID> -pr activemqserver -c 0
```

4. Add the Messaging Service to another node:

```
tsm topology set-process -n <nodeID> -pr activemqserver -c 1
```

5. Apply the configuration changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays

even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see [tsm pending-changes apply](#).

Remove a Node

If your Tableau Server installation includes a node you no longer need, you can remove it to simplify your installation, and to free up the hardware resources on that node.

Note: If you have Tableau Resource Monitoring Tool Agent installed on this node, you must remove it from the Resource Monitoring Tool Master Server Environment. For more information, see [Tableau Server Topology Changes](#).

Prerequisites for removing a node

There are prerequisites you must satisfy before you can remove a node from your Tableau Server cluster. If your node has one of a number of limitations, you need to address these before you can remove the node. The limitations include confirm that the node has been added with at least one process, and that the node does not include any process that is not also installed on another node.

If one of the following configuration limitations applies, you must take action before you can remove the node:

- If the node was just added using the Web UI, you need to apply pending changes before you can remove it. If you added it using the command line, you need to configure it with at least one process before you can remove it.
- If the node includes the only Repository instance, you need to move the Repository to another node. See [Move the Repository Process](#).

Tableau Server on Windows Help

- If the node is running the only instance of the File Store, you need to move the File Store to another node. See [Move the File Store Process](#).
- If the node is running an instance of the Coordination Service, you must deploy a new Coordination Service ensemble that does not include the node. See [Deploy a Coordination Service Ensemble](#).
- If the node is running the Messaging Service, you need to move the Messaging Service to another node. See [Move the Messaging Service Process](#).

Important: Do not use the `tableau-server-obliterate.cmd` script to remove a node. First remove the node using the TSM UI or the `tsm topology remove-nodes` command. This leaves the rest of the cluster in a good state. Later, if you want to re-add the node to the cluster, run the `tableau-server-obliterate.cmd` script on the node to completely remove Tableau. After removing Tableau from the node, restart the computer and then re-add the node using the normal steps for adding and configuring a node. For details on running the script, see [Remove Tableau Server from Your Computer](#).

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab and, under the node you want to remove, click **Remove Node**:

If a configuration limitation does not allow you to remove the node (if, for example, it includes a File Store that must first be decommissioned), a message will display letting you know this. See **Prerequisites** above for more information.

Note: If you just added the node, and have not configured it, you must first apply pending changes before you can remove the node.

3. Click **Pending Changes** at the top right, and **Apply Changes and Restart**.

Use the TSM CLI

Use the `tsm topology remove-nodes` command to remove a node from a cluster.

To remove a node from a cluster it must have been configured with a process at some point in the past. If you added a node using the CLI and want to remove it but have not configured any processes, you must add a process on it, run the `tsm pending-changes apply` command, and then remove the node. For example, you might add one instance of Cluster Controller to the node:

```
tsm topology set-process -n <nodeID> -pr
clustercontroller -c 1.
```

If you are removing a node you added using the Web UI, the Cluster Controller process is automatically added so you do not need to add it before removing the node.

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are changing:

```
tsm topology list-nodes -v
```

3. Remove a node using the `remove-nodes` command.

For example, to remove `node2` from an existing cluster:

```
tsm topology remove-nodes --node-names "node2"
```

If a configuration limitation does not allow you to remove the node (if, for example, it includes a File Store that must first be decommissioned), a message will display letting you know this. See **Prerequisites** above for more information.

4. Apply the changes:

```
tsm pending-changes apply
```

Configure Tableau Server for High Availability with Coordination Service-Only Nodes

The Coordination Service is built on [Apache ZooKeeper](#), an open-source project, and coordinates activities on the server, guaranteeing a quorum in the event of a failure, and serving as the source of "truth" regarding the server topology, configuration, and state. The service is installed automatically on the initial Tableau Server node, but no additional instances are installed as you add additional nodes. Because the successful functioning of Tableau Server depends on a properly functioning Coordination Service, we recommend that for server installations of three or more nodes, you add additional instances of the Coordination Service by deploying a new Coordination Service ensemble. This provides redundancy and improved availability in the event that one instance of the Coordination Service has problems.

The Coordination Service can generate a large amount of I/O as it communicates with other components of the server, so if you are running Tableau Server on computers that meet or just exceed the minimum hardware requirements, you may want to install Tableau Server in a configuration that uses Coordination Service-only nodes. This means installing Coordination Service on nodes that run no other server processes, and removing Coordination Service from any nodes that are running other server processes. This procedure explains how to do this. You can also run the Coordination Service ensemble on the same nodes running other Tableau Server processes. For details on how to do that, see [Deploy a Coordination Service Ensemble](#).

Important: The process to deploy a Coordination Service ensemble changed as of version 2020.1.0. If you are running an earlier version of Tableau Server, see the

documentation for that version. You can find documentation for all supported versions here: [Tableau Help](#)

Prerequisite

Before proceeding with the procedures in this topic, complete the following prerequisites:

- Install and Configure Tableau Server - Install Tableau on your initial node.
- Install and Configure Additional Nodes - Install Tableau on at least two additional nodes.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

Deploy an ensemble on Coordination Service-only nodes

One way to accommodate the high I/O impact of the Coordination Service is to deploy an ensemble on nodes that only run the Coordination Service and the Cluster Controller. The following steps illustrate how to deploy a Coordination Service ensemble on an existing multi-node Tableau Server cluster.

Note: For a core-based Tableau Server license, Coordination Service-only nodes do not count against the total count of licensed cores.

1. Add additional nodes to your cluster.

See [Install and Configure Additional Nodes](#).

2. If you added the new nodes using the TSM CLI, you need to configure the nodes with Cluster Controller (this step is not necessary if you added the nodes using the TSM Web UI because Cluster Controller is automatically added when you add a node with the Web UI).

On the initial node, open a command prompt as administrator.

3. From the initial node of the cluster, configure the new nodes with an instance of the Cluster Controller:

```
tsm topology set-process -pr clustercontroller -n <node4> -c 1
```

```
tsm topology set-process -pr clustercontroller -n <node5> -c 1
```

```
tsm topology set-process -pr clustercontroller -n <node6> -c 1
```

If prompted, sign in as a TSM administrator.

4. Apply the configuration changes. If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

```
tsm pending-changes apply
```

A warning about deploying a Coordination Service ensemble displays because you have deployed a multi-node cluster. If this is the only warning, you can safely override it using the `--ignore-warnings` option to apply the configuration changes in spite of the warning.

```
tsm pending-changes apply --ignore-warnings
```

5. Confirm that all nodes are up and running:

```
tsm status -v
```

6. On the initial node of the cluster, open a terminal session and type this command to stop Tableau Server:

```
tsm stop
```

7. Get the node IDs for each node in the cluster:

```
tsm topology list-nodes -v
```

8. Use the `tsm topology deploy-coordination-service` command to add a new Coordination Service ensemble by adding the Coordination Service to specified nodes. You must specify the node(s) that the Coordination Service should be added to. The command also makes the new ensemble the "production" ensemble (the ensemble in use) and removes the old ensemble.

Note: A "y/n" prompt displays confirming that a server restart will take place. To run the command without input, include the `--ignore-prompt` option.

For example, deploy the Coordination Service to three nodes of a six-node cluster:

```
tsm topology deploy-coordination-service -n <node4,node5,node6>
```

Wait until the command completes and you are returned to the system prompt.

9. Start Tableau Server:

```
tsm start
```

Add a Load Balancer

You can enhance the reliability of Tableau Server by running gateways on multiple nodes, and configuring a load balancer to distribute requests across the gateways. Unlike the repository process, which can be active or passive, all gateway processes are active. If one gateway in a cluster becomes unavailable, the load balancer stops sending requests to it. The load balancer algorithm you choose determines how the gateways will route client requests.

- **Kerberos:** If you will be using Kerberos authentication, you need to configure Tableau Server for your load balancer before you configure Tableau Server for Kerberos. For more information, see [Configure Kerberos](#).

Microsoft SSPI authentication is not supported with a load balancer.

- **Tested load balancers:** Tableau Server clusters with multiple gateways have been tested with Apache and F5 load balancers.

If you are using an Apache load balancer and creating custom administrative views, you need to connect directly to the Tableau Server repository. You cannot connect through the load balancer.

- **Tableau Server URL:** When a load balancer is in front of a Tableau Server cluster, the URL that's accessed by Tableau Server users belongs to the load balancer, not the initial Tableau Server node.
- **Single load balancer endpoint:** You must configure your load balancers for a single URL endpoint. You cannot configure different endpoint hosts to redirect to the same Tableau Server deployment. The single external URL is defined in `gateway.public.host` when you configure Tableau Server, as described in [Configuring Proxies and Load Balancers for Tableau Server](#).
- **Trusted host settings:** The computer running the load balancer must be identified to Tableau Server as a trusted host, as described in [Configuring Proxies and Load Balancers for Tableau Server](#).

Configure Tableau Server to work with a load balancer

The settings used to identify a load balancer to Tableau Server are the same ones that are used to identify a reverse proxy server. If your Tableau Server cluster requires both a proxy server and a load balancer, both must use a single external URL defined in `gateway.public.host` and all proxy servers and load balancers must be specified in `gateway.trusted` and `gateway.trusted_hosts`. See [Configuring Proxies and Load Balancers for Tableau Server](#).

Upgrade Tableau Server Overview

The topics in this section help you upgrade an existing installation of Tableau Server on Windows. They describe the recommended steps of planning and testing *before* actually performing the upgrade. There's information about best practices, and when you're ready to actually perform your upgrade, steps for upgrading a single node server and a multi-node installation. Where possible, we call out possible pitfalls and help you to avoid these.

Note: Use [Tableau Release Navigator](#) to search for features in Tableau Desktop, Server, and Prep, or to see a full list of features when comparing your current version of Tableau to a later one.

Looking for Tableau Server on Linux? See [Upgrade Tableau Server on Linux](#).

Choose your upgrade path

Blue/Green upgrades

Blue/green upgrades are a special type of upgrade approach that provide minimal downtime, but require a knowledgeable IT team and resources to implement. These are not for every organization, but for those who are equipped to handle them, they can be the right upgrade solution. For more information, see [Using a Blue/Green approach for upgrading Tableau Server](#).

Upgrading in place

Your upgrade steps depend on the version of Tableau Server on Windows you are upgrading from, the version you are upgrading to, and the install location of your existing version. Use the table below to find a link to the steps that apply to your upgrade situation.

Upgrade Type

Current version	Upgrading to version	Install location	Upgrade procedure
<i>What version are you upgrading from?</i>	<i>If you aren't sure how to find your version, see Determine your Tableau Server version below.</i>	<i>If you do not know where Tableau Server is installed, see Determine your Tableau Server install location below.</i>	<i>Upgrade steps to use</i>
2018.2.x or later	2018.2.x or later	default or non-default location	Upgrading from 2018.2 and Later (Windows)
2018.1.x or earlier	2018.2.x or later	default or non-default location	Upgrade from Tableau Server 2018.1.x or Earlier in the 2021.4 Server Help.

Determine your Tableau Server version

To see what version of Tableau Server you are running, sign in to Tableau Server and click the information icon ( or ) at the upper right of the Tableau Server window, then click **About Tableau Server**. Your server version is listed in the About Tableau Server dialog.

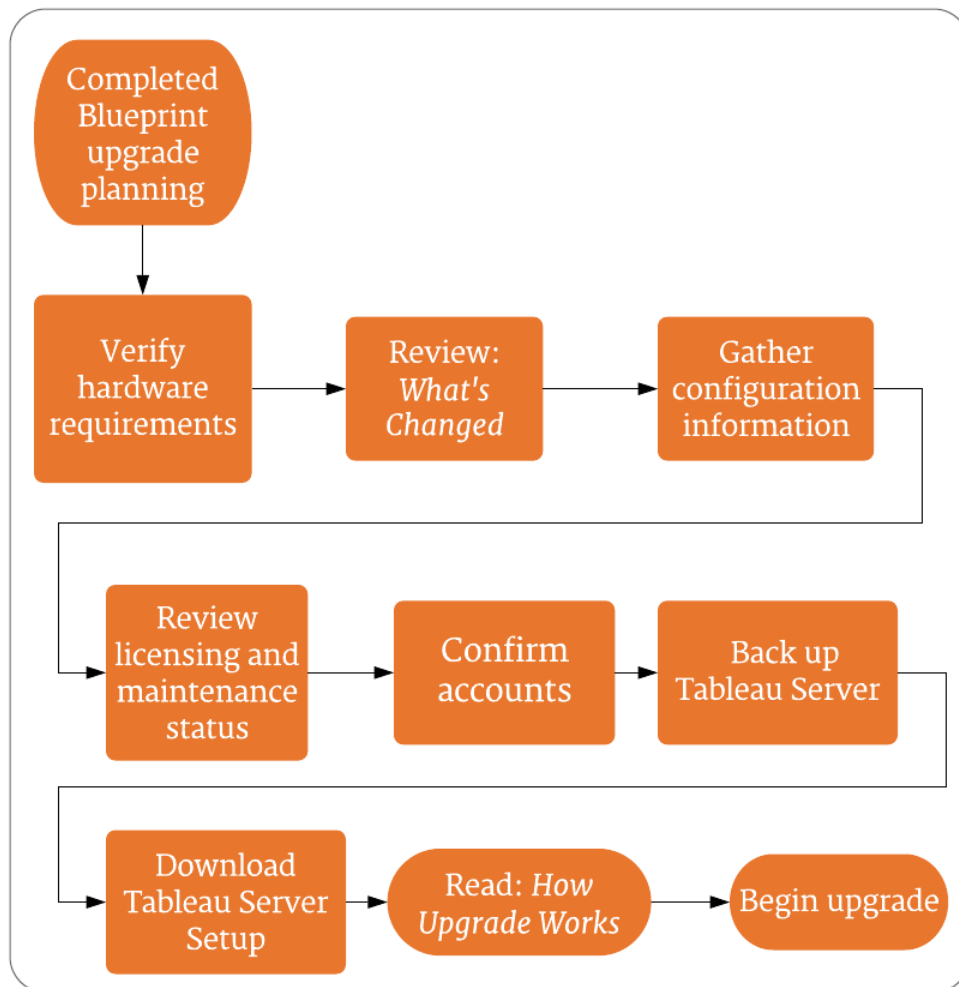

Determine your Tableau Server install location

Knowing where your current version of Tableau Server is installed is a key aspect of choosing the right upgrade path. By default Tableau Server version 2018.2 or later is installed to `C:\Program Files\Tableau Server\packages\`.

Versions before 2018.2 install to C:\Program Files\Tableau\Tableau Server-
\<version>. For more details about these versions, see [Upgrade Tableau Server Overview](#) in the 2021.4 Server Help.

Preparing for Upgrade

Follow the flow chart and the linked topics to prepare your environment for Tableau Server upgrade.

Release Navigator

Note: Use [Tableau Release Navigator](#) to search for features in Tableau Desktop, Server, and Prep, or to see a full list of features when comparing your current version of Tableau to a later one.

Server Upgrade - Minimum Hardware Recommendations

For production use, the computer on which you upgrade Tableau Server should meet or exceed the minimum hardware recommendations. These recommendations are general. Actual system needs for Tableau Server installations can vary based on many factors, including number of users and the number and size of extracts. If the Setup program determines that your computer does not meet the following recommendations, you will get a warning, but you can continue with the setup process. The minimum recommendations listed here are intended as general guidance. However the recommendations for your environment may vary. For more information, see the [Hardware recommendations section](#) of the [Recommended Baseline Configurations](#) topic.

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
Single node	<ul style="list-style-type: none">• 64-bit (x64 chipsets)• Must support SSE4.2 and POPCNT instruction sets• ARM-based processors are not supported	8 cores (16 vCPUs), 2.0 GHz or higher	Version 2022.3 and later: <ul style="list-style-type: none">• 128 GB Version 2021.4.0 to version 2022.1.x: <ul style="list-style-type: none">• 64 GB Version 2021.3.x and earlier:	50 GB

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
---------------------	------------------	------------	------------	------------------------

- 32 GB

If you are adding Tableau Prep Conductor to your Tableau Server installation, we recommend you add a second node and dedicate this to running Tableau Server Prep Conductor. This node should have a minimum of 4 cores (8 vCPUs), and 16 GB of RAM.

Multi-node and
enterprise
deployments

Contact Tableau for technical guidance.

Nodes must meet or exceed the minimum hardware recommendations, except:

- Dedicated Backgrounder nodes running up to two instances of backgrounder, where 4 cores may be acceptable.
- Dedicated node for Tableau Prep Conductor: Minimum of 4 cores (8 vCPUs), and 16 GB of RAM.
- Dedicated node for Independent Gateway: Minimum of 2 cores (4 vCPUs), 8 GB of RAM, and 100 GB free disk space.

Important: The disk space requirement cannot be checked until you initialize TSM.

- Free disk space is calculated after the Tableau Server Setup program is unzipped. The Setup program uses about 1 GB of space. You may need to allocate additional disk space depending on various factors like whether you will be using extracts.
- **Network attached storage space requirements for External File Store:** If you are planning to configure [Tableau Server with External File Store](#), you will need to estimate the amount of storage space to dedicate on your network attached storage.

Estimating the storage size: You must take into account the amount of storage needed for publishing and refreshing extracts. In addition, you must also take into account the

repository backup size unless you specifically choose the option to do your repository backup separately as described in the Option 2: Back up repository separately topic.

- Extracts:
 - Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.
 - Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.
- Repository Backup:
 - To obtain an estimate of the repository data, check the size of `<data directory>/pgsql/data/base` directory.
 - To obtain the exact size of the repository data, open the backup file and use the size of the `workgroup.pg_dump` file.
- Core count is based on "physical" cores. Physical cores can represent actual server hardware or cores on a virtual machine (VM). Hyper-threading is ignored for the purposes of counting cores.
- RAM shown is the minimum recommended for a single-node installation. Your installation may function better with more RAM, depending on activity, number of users, and background jobs, for example.

To see the full list of recommendations and to see the minimum requirements, see Minimum Hardware Requirements and Recommendations for Tableau Server. For hardware specifications Tableau uses internally for testing scalability, see Hardware recommendations for production installations.

For hardware recommendations for Tableau Server in the cloud, see the following:

- Selecting an AWS Instance Type and Size in the [Tableau Server on Windows in the AWS Cloud Administrator Guide](#)
- Selecting a Google Compute Engine Virtual Machine Type and Size in the [Tableau Server on Windows in the Google Cloud Platform Administrator Guide](#)
- Selecting a Microsoft Azure Virtual Machine Type and Size in the [Tableau Server on Windows in Microsoft Azure Administrator Guide](#)

Determining Computer Hardware

To determine how many physical cores a computer has, the Tableau Server setup program queries the operating system. To view hardware information that the setup program detected on your computer, open the `tabadmin.log` file in the following folder on the computer where you are installing Tableau Server:

```
<install directory>\ProgramData\Tableau\Tableau Server-
\logs\tabadmin.log
```

In the `tabadmin.log` file, look for lines similar to the following. These lines provide information about the physical and logical cores that the setup program detected and that it used to determine the core count that is being used for licensing.

```
2015-04-09 14:22:29.533 -0700_DEBUG_10.36.2.32:<machine name>:_pid-
d=21488_0x2cd83560__user=__request=__ Running hardware check

2015-04-09 14:22:29.713 -0700_DEBUG_10.36.2.32:<machine name>:_pid-
d=21488_0x2cd83560__user=__request=__ Detected 12 cores and
34281857024 bytes of memory

2015-04-09 14:22:29.716 -0700_DEBUG_10.36.2.32:<machine name>:_pid-
d=21488_0x2cd83560__user=__request=__ Hardware meets recommended
specifications. Default values will be used.
```

Manually determining the number of cores on your computer

To determine manually how many physical cores your server has, you can use the Windows Management Instrumentation Command-line tool (WMIC). This is useful if you do not know

whether your computer will meet the minimum hardware requirements for installing Tableau Server.

1. Open a command prompt.
2. Enter the following command:

```
WMIC CPU Get DeviceID,NumberOfCores
```

The output will display the device ID or IDs and the number of physical cores the computer has.

```
Administrator: Command Prompt

C:\>WMIC CPU Get DeviceID,NumberOfCores
DeviceID  NumberOfCores
CPU0      6
CPU1      6

C:\>_
```

In this example, there are two CPUs, each with six cores, for a total of twelve physical cores. This computer would satisfy the minimum hardware requirements for installing Tableau Server.

The following command shows a longer version that lists the logical processors as well as the physical cores.

```
WMIC CPU Get DeviceID,Num-
berOfCores,NumberOfLogicalProcessors,SocketDesignation
```

```

Administrator: Command Prompt
C:\>WMIC CPU Get DeviceID,NumberOfCores,NumberOfLogicalProcessors,SocketDesignation
DeviceID    NumberOfCores  NumberOfLogicalProcessors  SocketDesignation
CPU0        6              12                        CPU 1
CPU1        6              12                        CPU 2
C:\>_

```

In the above example, the server has a total of twelve physical cores, resulting in 24 logical cores.

Continue to Server Upgrade - Review What's Changed.

Server Upgrade - Review What's Changed

This topic includes a list of important product changes in Tableau Server, beginning with version 2019.1. The changes listed in this topic may impact the upgrade process itself, or they may impact functionality after you have upgraded. Read these changes carefully and make note of the changes and remediation steps that you'll need to take. Include these remediation steps as part of your upgrade process or post-upgrade configuration plan.

This list is cumulative, so if you are upgrading from an early version (for example, 2019.1), read the list of changes for every version between your version and the version you are upgrading to. You can also download the workbook with the list and use it to create your own customized checklist.

To develop a more robust verification and testing plan, we recommend that you also review new features before you upgrade. To see a full list of all new and changed features, select everything listed in the **Status** filter.

Continue to Server Upgrade - Gather Configuration Details.

Server Upgrade - Gather Configuration Details

If you are running an in-place upgrade (you're not updating hardware as part of your upgrade), then nearly all the configuration data is preserved. Strictly-speaking, you do not need to gather all of the configuration information in this case. However, we recommend gathering the information as detailed in this topic. In the worse case scenario, should upgrade fail, then you will have a record of all configuration information should you need to restore. In any case, you can use the configuration details you collect to verify the upgrade when it's complete.

Take screen shots

A relatively quick way to capture the basics of your configuration is to take screen shots of the TSM web interface pages and the Tableau Server admin area.

Click through all visible pages and take screen shots:

- Sign in to Tableau Services Manager Web UI
- Sign in to the Tableau Server Admin Area

Record object counts

When you are in Tableau Server admin area, count and record the following in each site:

- Projects, workbooks, views, data sources
- Users and groups

Gather asset files

Many of the supporting files (certificates, IdP metadata, logos, etc) that you upload to Tableau Server are not accessible with TSM after you upload them. Specifically, files that are uploaded and managed by the Client File Service are renamed and obfuscated before they are distributed across the deployment. This process also parametrizes the file attributes that are required by Tableau services. As a result, files are not mapped to a single file location on the file system for the following files. If you have uploaded any of the following files, be sure to have copies of them saved off of the computer that is running Tableau Server:

- SAML certificate file
- SAML key file
- SAML IdP metadata file
- OpenID.static.file
- Kerberos.keytab file
- LDAP Kerberos keytab file
- LDAP Kerberos conf file
- Mutual SSL certificate file
- Mutual SSL revocation file
- Customization header logo file
- Customization sign-in logo file
- Customization compact logo file

Tableau Server on Windows Help

Gather custom configuration information

Some configuration information is not displayed in the TSM or Tableau Server web pages. This section includes configuration details that you may need to gather depending on how you've customized your Tableau deployment.

Secure SMTP

If you have configured TLS for Tableau Server, then you will need to record the TLS-related configurations, which are not included in the **Email Server** configuration of the TSM Web UI.

To gather the TLS-related configurations, you must run `tsm configuration get` with the following key values:

- `svcmonitor.notification.smtp.ssl_enabled`
- `svcmonitor.notification.smtp.ssl_required`
- `svcmonitor.notification.smtp.ssl_check_server_identity`
- `svcmonitor.notification.smtp.ssl_trust_all_hosts`
- `svcmonitor.notification.smtp.ssl_ciphers`
- `svcmonitor.notification.smtp.ssl_versions`

For example, to retrieve the list of ciphers that are configured for SMTP TLS, run the following command:

```
tsm configuration get -k svcmonitor.notification.smtp.ssl_ciphers
```

You can find more information about each of the keys above in the TSM CLI section of *Configure SMTP Setup*.

Analytics extensions

If you have configured analytics extensions (formerly referred to as "external services"), you will need to record your configuration information. Upgrading to Tableau Server 2020.2 or later will remove all configuration for this feature.

To retrieve the analytics extensions configuration from Tableau Server versions 2019.1 through 2020.1, run the following command:

```
tsm security vizql-extsvc-ssl list
```

To retrieve the password that is stored for the analytics extensions connection (if any), run the following tsm command:

```
tsm configuration get -k vizqlserver.rserve.password
```

You should also have a copy of the certificate for analytics extensions if you've configured SSL.

External Repository

This applies only if you are using the External Repository configuration with Tableau Server. If you are not sure if this applies to you, see [Tableau Server External Repository](#).

If you are using an External Repository, you may need to take additional steps when upgrading.

- **No version change**—If there is no version change in PostgreSQL, there are no special actions required.
- **Minor version change**—If there is a minor version change in PostgreSQL, you need to upgrade your external repository before upgrading Tableau Server. In most cases there are in-place methods for doing so. The method you use depends on the location of your repository and is beyond the scope of this documentation.
- **Major version change**—If there is a major version change in PostgreSQL, you need to follow the steps described in [Upgrade Tableau Server with External Repository for a New Major Version of PostgreSQL](#).

Steps include:

1. Creating a new instance of PostgreSQL DB. For more information, see:
 - [Create a PostgreSQL DB Instance on AWS Relational Database Service \(RDS\)](#)
 - [Create a Azure Database PostgreSQL Instance on Azure](#)
 - [Create a PostgreSQL Instance on Google Cloud](#)
 - [Create a PostgreSQL Database as a Stand-alone Installation](#)
2. Creating a configuration file and download the SSL certificate file for the new instance that you created in Step 1.

Tableau Server on Windows Help

During upgrade, you will need to point Tableau Server to the new instance using the configuration file. The upgrade process will migrate the content from your current external repository to your new instance. For more details, see [Upgrade Tableau Server with External Repository for a New Major Version of PostgreSQL](#).

External File Store

There are no special steps, actions, or configuration required when upgrading Tableau Server configured with External File Store. You can upgrade Tableau Server using the normal procedure.

Port customization

If you have changed the dynamic port range or have configured ports manually for Tableau Server, record the changes you have made.

Run the following command:

```
tsm topology list-ports
```

For more information see [Tableau Services Manager Ports](#).

Proxy customization

If you are using OAuth and have made any changes to the `net.properties` file for Tableau Server in the `<drive>:\Program Files\Tableau\Tableau Server-\packages\repository.<version>\jre\conf` folder, you should record the changes you have made. The upgrade process creates a new `net.properties` file and you may need to update the new one after you upgrade.

You can save a copy to a safe location and use it after upgrade to compare to the newly created file for any differences.

For more information see [Configure a proxy for OAuth authentication](#) in the Tableau Desktop and Web Authoring Help.

Continue to [.Server Upgrade - Verify Licensing Status](#)

Server Upgrade - Verify Licensing Status

Prior to upgrading Tableau Server, review the product keys that are currently installed and compare them to the product keys, maintenance expiration, and license expiration end dates that are listed in the Tableau Customer Portal.

It is important that all expiration and end dates associate with product keys are up-to-date before you upgrade.

Step 1: View license expiration information.

Run the following command to view all licenses that are installed on your Tableau Server installation:

```
tsm licenses list
```

The `tsm licenses list` command returns all licenses, each with a number of fields. For upgrade, you need to make note of two fields:

- For each subscription license, make note of the date in the LIC EXP field. LIC EXP displays the date that the license expires and Tableau Server will stop working.
- For each legacy perpetual key, make note of the MAINT EXP field. MAINT EXP displays the date that the maintenance contract for the Tableau Server deployment expires.

Step 2: Compare license expiration dates from TSM to your licenses in [Tableau Customer Portal](#).

Step 3: If required, update licenses.

If your TSM maintenance date is not current or the expiration date will occur soon or is not the same as the date listed in the Tableau Customer Portal, refresh the license.

To refresh the license:

Tableau Server on Windows Help

1. If the computer where you are running Tableau Server has been configured to connect to the internet through a forward proxy, follow the procedure in the topic, [Configure Product Key Operations with Forward Proxy](#), before continuing.
2. Open TSM in a browser:

`http://<tsm-computer-name>:8850`
3. Click **Configuration** and **Licensing** and click **Refresh All**:

Product Key	Seat Licenses	Expires
 	15	May 1, 2018
trial	10	January 22, 2018

If this does not update the maintenance or expiration end date but the Tableau Customer Portal does show more current end dates, please contact [Tableau Technical Support](#).

Reactivating the product key will be part of the upgrade process.

Continue to Server Upgrade - Verify Accounts.

Server Upgrade - Verify Accounts

Before you upgrade Tableau Server, verify that you have passwords for two accounts:

- An account that is a member of the local administrators group: The account that you use to install Tableau Server must be a member of the local administrators group.
- Run As service account: If your organization uses Active Directory as the identity store and/or if you have configured Tableau Server to connect to data sources in Active Dir-

ectory, then it's a best practice to keep the Run As service account credentials at hand as you run upgrade.

Tableau Server Setup will not modify existing directory permissions during the upgrade process. But it's a best practice to verify any non-default permission configurations before you run Setup:

- If you have installed Tableau Server on to a non-default drive (default is typically `C:\Program Files`), then verify that permissions for the Run As service account are compliant with the required permissions specified in Installing in a non-default location.
- In addition, if you have scoped permissions on the computer running Tableau Server, verify that those permissions are compliant with the required directory permissions specified in Windows Accounts and Permissions.

Continue to Server Upgrade - Back Up Tableau Server.

Server Upgrade - Back Up Tableau Server

We *strongly* recommend that you make a backup of your installation of Tableau Server before beginning the upgrade process. A backup made before you start the upgrade provides data that you'll need to set up a test version of the upgraded environment, and it also gives you the ability recover if the upgrade process fails. Backups are not an include step during upgrades, except when the upgrade includes a minor version upgrade to PostGRES and then a pg-only upgrade is created for internal use during upgrade.

Notes:

- We recommend you disable subscriptions and scheduling in your production environment immediately before taking the backup, and reenable them after the backup is complete. Doing this will help avoid having your users receive duplicate subscriptions and email messages when you restore your backup in your test environment.
- The full backup can take a while if you have a large installation or a lot of extracts.
- Any changes made between the time you took the backup and the time you do the

upgrade are lost because they aren't included in the backup.

- Remove Unneeded Files.

To back up server configuration data, use the `tsm settings` command.

When you use the `tsm maintenance backup` command, the current date is appended to the backup file:

```
tsm maintenance backup -f <backup_file> -d
```

For more information, see [tsm maintenance backup](#).

Continue to Server Upgrade - Download Setup.

Server Upgrade - Download Setup

You must download and copy the Tableau Server Setup program to the computer running Tableau Server. If you are running a multi-node deployment of Tableau Server, copy the Setup program to each node in the cluster.

To get the latest version of Tableau Server software, go to the [Customer Portal](#). When you purchase Tableau, you get a user name and password to sign in to the Customer Portal.

Important: Always download and install the latest maintenance release for the version you are upgrading to.

Continue to How Tableau Server Upgrade Works.

How Tableau Server Upgrade Works

When upgrading from Tableau Server 2018.2 or later, you do not uninstall the previous version. The upgrade process is designed to install a new version side-by-side with your existing version, and then switch from the earlier version to the later one.

When doing a TSM-to-TSM upgrade (version 2018.2.x to later version), you must leave your existing version in place and running until just before you upgrade using the upgrade script. If you uninstall your existing version before upgrading, you will not be able to upgrade. For your end-users, this has the impact of reducing downtime because you install your new version while the existing version is running. The only time the server is not running is during the period the upgrade script is actually upgrading to the new version.

After installing the new version and upgrading, you can uninstall the previous version when you choose to do so. You can leave the older version installed indefinitely, though one reason you might choose to uninstall it is to free up disk space used by files specific to the older version. To understand the difference between uninstalling Tableau Server and completely removing all aspects of Tableau Server, see [Uninstall Tableau Server](#).

Upgrading Tableau Server requires a stop and start the server as part of the upgrade process. During this stop/restart Tableau Server is unavailable.

What's Changed - Things to Know Before You Upgrade

Beginning with version 2020.2, this topic has been merged with [What's New in Tableau Server](#), to provide a single location for new and changed features and behavior in Tableau Server. See [Tableau Server Release Notes](#) for both new features and for changes introduced in this and earlier versions.

Note: Use [Tableau Release Navigator](#) to search for features in Tableau Desktop, Server, and Prep, or to see a full list of features when comparing your current version of Tableau to a later one.

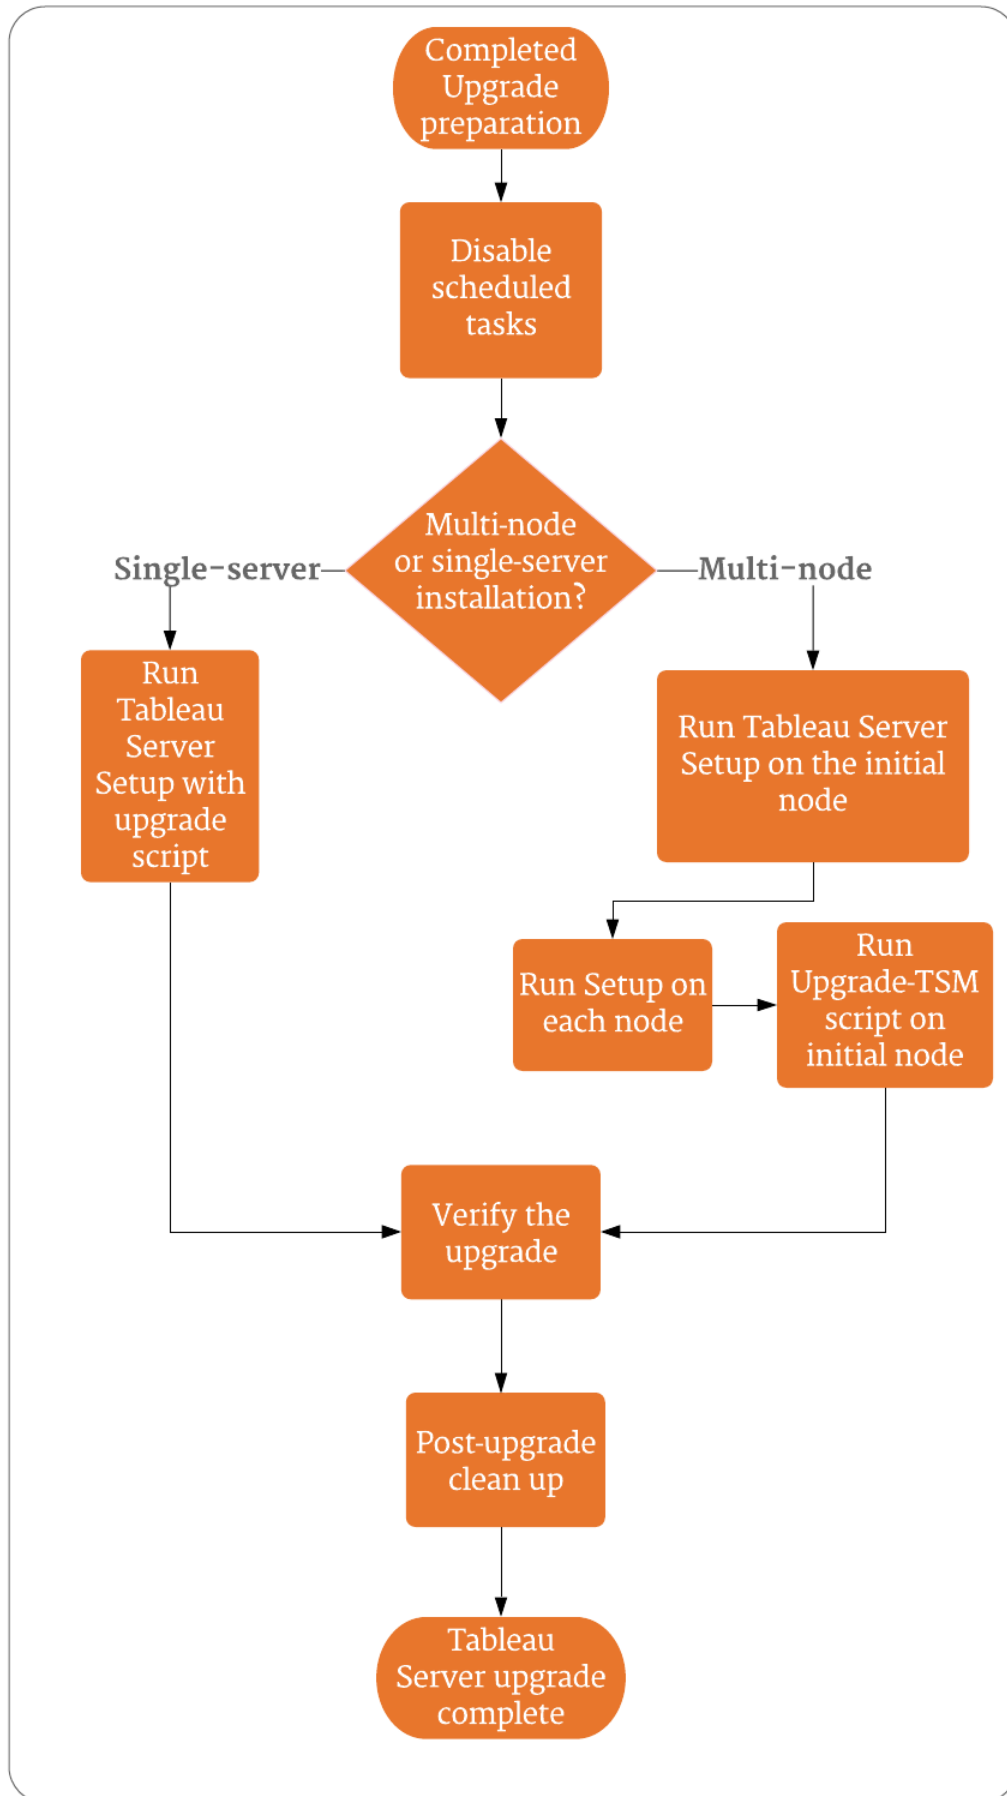

Upgrading from 2018.2 and Later (Windows)

Follow the flow chart below and the linked topics to perform an in-place upgrade of Tableau Server.

Tableau Server on Windows Help

Before you start the upgrade, make sure you have completed the Upgrade Preparation, For more details, see [Preparing for Upgrade](#).

If you are migrating Tableau Server to new hardware as part of your upgrade, see [Migrate to New Hardware](#).

Support and services to help with Tableau Server upgrades

Tableau Server upgrades require planning and testing. Upgrades are generally done during times when users are not on Tableau Server. If you plan an upgrade over a weekend and anticipate needing Tableau Technical Support, see the [Technical Support Programs](#) information on the Tableau web site. Availability depends on the level of support you have. If you would like Tableau to assist with the planning and upgrading of your Tableau Server installation, see our [Tableau Global Services Server Upgrade](#) page for details.

Server Upgrade - Disable Scheduled Tasks

Though not strictly required, we recommend disabling scheduled tasks before you perform the upgrade.

Run the following procedure to disable all scheduled extract refreshes, flows, and subscriptions.

1. Sign in to the Tableau Server Admin Area as the Tableau Server administrator.
2. Go to the server-wide Schedules page:
 - On a Tableau Server where only a single (Default) site exists, click **Schedules** in the left pane.
 - On a Tableau Server with more than one site, click **Manage all sites** in the drop-down menu on the top of the left pane, and then click **Schedules**.
3. On the Schedules page, click **Select All**.
4. On the **Actions** menu, select **Disable**, and then click **Disable** in the resulting prompt.

Continue to: [Single-Server Upgrade -- Run Setup](#), or [Multi-node Upgrade -- Run Setup](#)

Single-Server Upgrade -- Run Setup

Run Setup

Follow these steps to upgrade a single-node installation of Tableau Server version 2018.2 or later.

1. Log onto the computer with an account that is a member of the local administrators group.
2. Navigate to the folder where you copied the Tableau Server Setup program and run it.
3. The Setup program checks system resources to confirm that the computer satisfies the minimum requirements and recommendations.
4. The Setup program displays the location of your existing version and will install the new version side-by-side in the same location. You cannot change the location.
5. When the installation is done, the last page of the Setup program tells you that the upgrade is not yet complete. You need to run an upgrade script, `upgrade-tsm`, to complete the upgrade. If Tableau Server is running, the script will let you know, and will offer to stop it. Tableau Server must be stopped to complete the upgrade.

Note: Beginning in version 2020.4.0, if the upgrade script fails, details about the failure display in the command window and you can rerun the script to try the upgrade again. The script restarts at the point it failed. This saves time and is a good first step if your upgrade fails. For more information, see [Upgrade fails on 2020.4.0 or later](#).

Run the upgrade script in one of two ways.

- From the Setup program:
 - a. Select **Automatically launch the upgrade script**, and click **OK**:

- b. A command window will open for the script. Because you are logged in as a user with local administrator rights, the script will run using your credentials. If you are prompted, enter your password.

Clicking **OK** will close the Setup program dialog. If you cleared the option to automatically launch the upgrade script, you will need to run the script manually, from the command line.

- On the command line:

- a. On the initial node, open a command prompt as administrator.

You must open a new command window because the Setup program updates the path for the new installation.

- b. Navigate to the scripts folder for your new installation.

By default:

```
C:\Program Files\Tableau\Tableau Server-  
\packages\scripts.<version_code>\
```

- c. Run the upgrade script:

```
upgrade-tsm
```

Because you are logged in as a user with local administrator rights, the script will run using your credentials. If you are prompted, enter your password. You can specify a different user and password when you run the script using `--username` and `--password` options.

To see all options for the `upgrade-tsm` script, use the `-h` option:

```
upgrade-tsm -h
```

6. Start Tableau Server. You can do this from the TSM web UI or from a command prompt:

- In TSM, click **Tableau Server is stopped**, and **Start Tableau Server**:

- From a command prompt:
 - a. Open a new command prompt as administrator.
 - b. Enter this command:

```
tsm start
```

If you get an error that the command is not recognized, close all command windows and then open a command prompt as administrator.

7. The upgrade process leaves your existing folders in place. You can identify these by the version code. For example:

```
C:\Program Files\Tableau\Tableau Server\packages\
```

Continue to Verify Tableau Server Upgrade.

Multi-node Upgrade -- Run Setup

Run Setup

1. Log onto the initial node with an account that is a member of the local administrators group.
2. Navigate to the folder where you copied the Tableau Server Setup program and run it. This will install the new version of Tableau Server side-by-side with your existing, running version.
3. The Setup program checks system resources to confirm that the computer satisfies the minimum requirements and recommendations.
4. The Setup program displays the location of your existing version and will install the new version side-by-side in the same location. You cannot change the install location.
5. When the installation is done on the initial node, the last page of the Setup program tells you that the upgrade is not yet finished. You need to run an upgrade script to complete

the upgrade. Leave the Setup window open on the initial node and continue with your installation on all other nodes in the cluster.

Important: You *must* install the new version on every node before you run the upgrade script. *Do not run the upgrade script* until after you have installed the new version on all nodes in your cluster.

Continue to Multi-node Upgrade -- Run Setup on Each Node.

Multi-node Upgrade -- Run Setup on Each Node

Run Setup

On each additional node, navigate to the folder where you copied the Tableau Server Setup program and run the Setup program as you did on the initial node. This will install the new version of Tableau Server on each node, side-by-side with your existing, running version.

When the installation is done on each additional node, the last page of the Setup program tells you that the upgrade is not yet finished. Make sure **Automatically launch the upgrade script** is *not* selected, and click **OK** to close the Setup window. You will run the upgrade script after the new version is installed on all nodes.

Continue to Multi-node Upgrade -- Run Upgrade Script.

Multi-node Upgrade -- Run Upgrade Script

Run Upgrade script

1. After you have installed the new version on *every node in the cluster*, run the upgrade script on the initial node. If Tableau Server is running, the script will let you know, and offer to stop it. Tableau Server must be stopped to run the upgrade script.

If the final Setup screen is still open, you can select **Automatically launch the upgrade script** and a command window will open to run the script. Alternately, you can run the script directly from a command prompt.

Note: Beginning in version 2020.4.0, if the upgrade script fails, details about the failure display in the command window and you can rerun the script to try the upgrade again. The script restarts at the point it failed. This saves time and is a good first step if your upgrade fails. For more information, see [Upgrade fails on 2020.4.0 or later](#).

- To run the upgrade script from the Setup program:
 - a. Select **Automatically launch the upgrade script** and click **OK**:

- b. A command window will open for the script. Because you are logged in as a user with local administrator rights, the script will run using your credentials. If you are prompted, enter your password.

Clicking **OK** will close the Setup program dialog. If you cleared the option to automatically launch the upgrade script, you will need to run the script manually, from the command line.

- To run the upgrade script from a command prompt:

- a. Open a command prompt as administrator.

You must open a new command window because the Setup program updates the path for the new installation.

- b. Navigate to the scripts directory for the new version you just installed.

By default:

```
C:\Program Files\Tableau\Tableau Server-  
\packages\scripts.<version_code>\
```

- c. Run the upgrade script:

```
upgrade-tsm
```

Because you are logged in as a user with local administrator rights, the script will run using your credentials. If you are prompted, enter your password. You can specify a different user and password using the `--user-name` and `--password` options.

To see all options for the upgrade-tsm script, use the `-h` option:

```
upgrade-tsm -h
```

The upgrade script will take some time to complete.

2. When the upgrade script completes, start Tableau Server. You can do this from the TSM web UI or from a command prompt:

- In TSM, click **Tableau Server is stopped**, and **Start Tableau Server**:

- From a command prompt:
 - a. Open a new command prompt as administrator.
 - b. Enter this command:

```
tsm start
```

Continue to Verify Tableau Server Upgrade.

Verify Tableau Server Upgrade

Work through the sections of this topic to verify if server upgrade was successful.

Verify Tableau Service processes

Start your verification process by signing into TSM with the command line and verifying the status of Tableau Server processes.

1. Open a new command prompt as a user with administrator access.

For more information on using the tsm command line, see Using the tsm CLI.

2. Run the following command to view the status of all the Tableau Server processes: `tsm status -v`.

What if I get an access denied error when I attempt to run TSM commands?

Verify that the account you are using is a member of the Local Administrators group on the Windows computer where you are installing Tableau Server.

Verify TSM global settings

As part of the preparation for upgrade, you should have taken screen shots of the TSM web UI settings. Sign in to Tableau Services Manager Web UI and compare the settings with the screen shots.

Enable subscriptions and scheduling

1. Sign in to the Tableau Server Admin Area as the Tableau Server administrator.
2. Go to the server-wide Schedules page:
 - On a Tableau Server where only a single (Default) site exists, click **Schedules** in the left pane.
 - On a Tableau Server with more than one site, click **Manage all sites** in the drop-down menu on the top of the left pane, and then click **Schedules**.
3. On the Schedules page, click **Select All**.
4. On the **Actions** menu, select **Enable**, and then click **Enable** in the resulting prompt.

Verify user access

With a user account, sign in to Tableau Server with Tableau Desktop and a browser.

If Tableau Server is available from outside your organization, verify connectivity from the internet.

If your organization supports mobile connectivity to Tableau Server, sign in to server with a mobile device.

If are using OAuth and cannot connect from Tableau Desktop, confirm that the `net.properties` file does not need to be updated. For more information, see [Proxy customization](#)

Tableau Server on Windows Help

View published workbooks

With a user account, sign in to Tableau Server and browse published workbooks. Open workbooks to view them in a browser

Verify publishing workbooks and data sources

Using an account with a Creator license, verify web authoring functionality to connect to data, and to create and publish workbooks and data sources:

- [Connect to Data on the Web](#)
- [Publish a Data Source on the Web](#)
- [Upload Workbooks to a Tableau Site](#)

Verify Tableau Prep Builder

If your organization is running Tableau Prep Builder, verify that you can connect to data, open a flow, and other Prep tasks. See [Tableau Prep: Connect to Data](#).

Verify count of Tableau objects

As part of upgrade preparation, you should have noted how many projects, workbooks, views, data sources, users, and groups are in your deployment. Verify that all objects still appear.

Sign in to the Tableau Server Admin Area as the Tableau Server administrator.

- Verify count of projects, workbooks, views, data sources
- Verify count of users and groups

Verify API functionality

If your organization has deployed or developed content with Tableau APIs, verify that these are operational.

REST API

Verify REST API access and authentication by running the sample cURL from [Get Started Tutorial: Introduction and Set Up](#):

```
curl "https://MY-SERVER/api/3.8/auth/signin" -X POST -d @signin.xml
```

Content of signin.xml:

```
<tsRequest>
  <personalAccessTokenName="MY_PAT_NAME"
    <credentials name="username" password="password" >
      <site contentUrl="MarketingSite" />
    </credentials>
  </tsRequest>
```

Example response:

```
<tsResponse version-and-namespace-settings>
  <credentials token="12ab34cd56ef78ab90cd12ef34ab56cd">
    <site id="9a8b7c6d-5e4f-3a2b-1c0d-9e8f7a6b5c4d"
      contentUrl="MarketingSite"/>
    </credentials>
  </tsResponse>
```

Compatibility testing

For other developed features, perform compatibility testing to verify that the upgraded version of Tableau Server operates as expected with your existing solutions:

- Dashboard Extensions
- JavaScript API for embedded Tableau
- Connectors (Web Data Connector, Tacos)

Go to Post Upgrade Cleanup.

Post Upgrade Cleanup

As discussed in *How Tableau Server Upgrade Works*, the Tableau Server upgrade process installs a new version side-by-side with your existing version. Now that upgrade is complete and verified, you can remove the older version of Tableau Server to free up disk space. This is an optional step.

Uninstall previous version

To uninstall a version of Tableau Server:

1. Open Control Panel, click **Uninstall a program**, and locate the version you want to uninstall.

Be sure you select the correct version to uninstall:

- Uninstalling previous versions of Tableau Server does not impact the running version and simply removes unnecessary files from those previous versions.
- **Do not** uninstall the current, running version. Uninstalling the current, running version of Tableau Server stops server and removes server-specific files and folders, but may leave some elements behind. Uninstalling does not create a backup of your repository data.

2. With the Tableau Server version selected, click **Uninstall**.

Delete 'Tableau Server' folders from `\packages` directory

After an upgrade, you will see multiple versions of Tableau Server folders in the `\packages` folder. When the upgrade is completed successfully, you can delete the folders related to the older version you upgraded from. You can identify these by the version code in the folder name. For example, `scripts.<version_code>`. For more information about version codes, see [View Server Version](#).

Using a Blue/Green approach for upgrading Tableau Server

While many organizations are well-served by performing an in-place upgrade of Tableau Server, other organizations with mission-critical use of Tableau may want a more robust, enterprise-grade upgrade approach which uses investments of additional effort and resources to reduce risk and impact. In these cases Tableau recommends a “Blue/Green” upgrade approach to achieve that outcome, characterized by:

- Reliable deployment of applications into a freshly-configured host non-production environment (versus an in-place upgrade)
- Performing pre-production testing of the new version in your non-production environment to validate business-critical functionality, including testing common use cases to detect changes in behavior that may impact the organization

- Testing in production-identical environments to validate integrations and resource requirements
- The ability to roll back to the previous version rapidly

This high-level guidance describes a Blue/Green approach to upgrades that has been successfully used by many of our biggest customers to upgrade Tableau Server (and other mission-critical applications) with confidence. Blue/Green upgrades are a [long-established industry practice](#); there are many variations and the specific steps below are one possible path. If you're seeking specific guidance on customizing this approach for your organization's next upgrade, talk to your Premium Support Technical Account Manager, or discuss a services engagement with your account executive or delivery partner.

The Blue/Green approach involves installing a new version of Tableau Server in a non-production environment (your "Green" installation) that mirrors the configuration of your existing production environment (your "Blue" installation). For purposes of your Tableau license, note that Tableau grants a standard right to two (2) non-production environments to support the single production environment in your deployment, as further described in the governing license agreement. These non-production environments should be able to be taken down and used for this method consistent with the intended use of a test environment as described in this Tableau Knowledge Base article: [Licensing a Tableau Server Test Environment](#).

By copying your content from the production environment to the Green installation in your non-production environment (for example, your test environment), you can create an upgraded instance of Tableau Server with minimum downtime and the safety net of having the original production installation to fall back to if necessary. Once you determine all your critical content in the Green environment is functional, switch your users over to the new environment (Green). Your Green environment becomes your production environment, and your original installation (Blue environment) can be maintained as a non-production environment to support your next upgrade.

What follows is a high-level outline of the steps necessary to use Blue/Green as an approach to upgrade Tableau Server. These assume you have a load balancer or DNS that allows you to redirect user traffic from one installation to the other, and that you have downloaded the new version of Tableau you want to upgrade to.

Important: Your Blue/Green installations should be treated as production environments. They should not serve as disaster recovery or general testing environments. For more details on Disaster Recovery please see [Disaster Recovery](#) in the Tableau Blueprint.

1. Create a second installation of servers that mirrors your production installation of Tableau Server as closely as possible. This second environment is your Green installation, a non-production environment. It should have a similar capacity, resources, and configuration as your production environment (“Blue”) because your Green instance will become your production instance after the upgrade.
2. Create an initial backup of your Tableau Server Blue installation. You’ll use this for initial user acceptance testing (UAT) in Green. Later, you’ll create a final, up-to-date backup to use before actually switching from Blue to Green. For details on creating backups, see [Back up Tableau Server Data](#). You will also need to export the settings for the Blue installation. Some settings must be manually recreated in the Green environment. For more information, see [Backup assets that require a manual process](#)
3. Install the new version of Tableau Server in Green. You should specify the same Identity Store type and Run As service account as you use in Blue.
4. Restore the initial backup from Blue into Green. Import the settings you exported from the Blue installation. You may have to manually recreate some of the settings in your Green environment. See [Restoring core Tableau Server functionality](#).
5. Disable any scheduled tasks in Green to avoid sending duplicate messages while testing, and to avoid overloading database resources. For details, see [Server Upgrade - Disable Scheduled Tasks](#).
6. Test the Green installation to confirm it is functioning as expected. Perform User Acceptance Testing (UAT), and simulate any load testing if desired. If you have scripts or API integration with Tableau, you should test these as well. The more complete your testing, the better prepared you will be to address any discrepancies between your original Blue

installation and your new Green installation.

7. Prepare the Blue installation so you can create a backup and export settings you'll use for production in Green. This might mean restricting access to Tableau, or sending a message instructing users not to make any changes to their content and warning them that any changes made after you create your backup will be lost.
8. Create a final backup of Blue. This is the backup you will use to bring Green up to the most recent production content. If you do regular backups, you can use your latest production backup, keeping in mind that any changes or updates done in Blue after the backup is created will be lost. We recommend a "change freeze" on your production environment after this backup is taken, so no new workbooks or data sources are added, and there are no changes to existing content.
9. Export the settings in the Blue environment, paying attention to those assets you may need to handle manually. For more information, see [Restoring core Tableau Server functionality](#).
10. Restore the final Blue backup and import the Blue settings file to Green. Make any manual configuration changes necessary.
11. Perform UAT/sanity checks of Green content.
12. Reenable schedules for any jobs, subscriptions, and notifications you disabled in Step 5 above.
13. Switch your users to Green using a load balancer or DNS, and block access to Blue.
14. Verify that the Green server is functional as desired and monitor for production load issues. If you have Advanced Management, you can use the Resource Monitoring Tool to monitor performance.
15. (Optional) If you're not keeping your Blue environment for future upgrades, deactivate the Blue environment product keys:

- For Tableau Server 2021.4 and later activated with ATR, see [Deactivate Product Key](#).
 - For any version of Tableau Server not activated with ATR, see [Deactivate Product Key](#).
 - For Tableau Server 2021.3 and earlier activated with ATR, see [Move a Server ATR License to Another Tableau Server](#).
16. (Optional) If you're not keeping your Blue environment for future upgrades, stop the Blue environment and prepare it for decommissioning. For details about decommissioning, see [Remove Tableau Server from Your Computer](#).

Test the Upgrade

The best way to learn what impact a Tableau Server upgrade will have to your current environment is to test it. Knowing how an upgrade will affect your users and your server helps you plan and communicate before the actual upgrade, ensuring that your users will not be caught by surprise.

If you have a Tableau Server test environment this is a great place to test out the upgrade.

We recommend the following sequence for testing a Tableau Server upgrade:

1. [Prepare a test environment](#)
2. [Upgrade the test environment](#)
3. [Confirm that existing functionality works](#)
4. [Performance and user acceptance testing](#)
5. [Test new features](#)
6. [Communicate about the upgrade](#)

Prepare a test environment

To start, create a test environment that mirrors your production environment as closely as possible. The closer your test environment is to the actual environment you will be upgrading, the

more accurate a representation you will have of how the upgrade will impact you. This includes identical or similar hardware and operating systems, as well as the same authentication options and network access.

When you've got a test computer or virtual machine ready, follow these steps for creating a test environment.

1. On the existing production environment, create a backup of Tableau Server using the `tsm maintenance backup` command.

For more information, see [Create a pre-upgrade backup](#).

2. On your test environment, install a copy of the same version of Tableau Server as you have in your production environment.

Note: You can download the setup program for your current version from the [Alternate Downloads Site](#).

3. Restore your existing database data using the `tsm maintenance restore` command.

For more information, see [Restore from a Backup](#).

4. Manually replicate your existing Tableau Server configuration.

You need to manually configure certain aspects of your environment because when you restore the Tableau database it doesn't include configuration details and customizations.

Upgrade the test environment

Follow the appropriate steps for upgrading the test environment, based on your environment:

- [Upgrading from 2018.2 and Later \(Windows\)](#)

Confirm that everything works as expected

After you have the new version of Tableau Server installed and configured in your test environment, you are ready to test. You should test basic functionality, along with any special aspects of server that your organization relies on. For example, if there are key subscriptions that your organization relies on, make sure that you test those.

These are some areas of testing to consider:

- **Server processes.** Sign in to Tableau Server as a server administrator, and then open the Server Status page to confirm that all services and processes are running as expected (including on all additional nodes if this is a distributed installation).
- **User access.** Confirm that Tableau Server users can sign in. Test your normal user sign in process. Have some of your users participate in the testing to make sure they are able to sign in as expected, and that they can get to the same content that they have access to in your production environment.
- **Publishing workbooks and data sources.** Have users publish workbooks and data sources from Tableau Desktop to make sure this goes as you expect.
- **Viewing published workbooks.** Have users who are familiar with the content try to view published workbooks to make sure they appear as expected. Test views embedded in web pages (for example, in SharePoint pages).
- **Subscriptions and extract refreshes.** Manually run some extract refreshes to confirm that they complete successfully. Run some key scheduled extract refreshes to confirm that they complete as expected.
- **Permissions.** Confirm that permissions are still set as expected for users and content.
- **Command-line utilities and APIs.** If applicable, test the command line utilities (tsm and tabcmd) and programmatic access via APIs.

Performance and user acceptance testing

Use tools like Tabjolt, Replayer, and Scout to do performance and user acceptance testing on your test environment. For more information about these and other performance testing tools, see [Performance Monitoring Tools](#).

Test new features

Take a look at the new features that come with the version you are upgrading to, and at any features that were added between the version you currently have and the new version. Think about how to help your users understand the benefits of the features that apply to your environment.

For more information on new features, see [What's New in the Tableau Server Help](#).

Communicate about the upgrade

The best way to make an upgrade go smoothly is by letting your organization know ahead of time about the upgrade and how it might impact them. If you've had users help test, take advantage of their experience by having them help communicate the changes they saw while testing. You can also provide user access to the test environment if there are key people who should see the upgraded version before the actual upgrade.

Troubleshoot Tableau Server Install and Upgrade

Follow the suggestions in this topic to resolve common issues with Tableau Server. For additional troubleshooting steps based on process status viewed on the Status page, see [Troubleshoot Server Processes](#).

General Troubleshooting Steps

Many Tableau Server issues can be addressed with some basic steps:

Tableau Server on Windows Help

1. Make sure there is enough disk space on each computer running Tableau Server. Limited disk space can cause a failure to install, a failure to upgrade, or problems running Tableau Server.
2. Restart Tableau Server. Issues related to processes not fully started can be resolved by restarting Tableau Server in a controlled way. To restart Tableau Server, use the `tsm restart` command. This will stop all the processes associated with Tableau Server and then restart them.
3. Reindex Tableau Server. Issues related to indexing can be resolved by reindexing Tableau Server. To reindex Tableau Server, use the `tsm maintenance reindex-search` command. For more information, see Reindexing Tableau Server Search & Browse below.
4. Restart the computer on which Tableau Server is running. Some issues, such as those related to data source connectivity, can be resolved by restarting the server computer.

Common Tableau Server Install Issues

Installation logs location

The installation logs are written to the `\Temp` directory of the user account that is running Setup. In most cases, this is located at `C:\Users\<user>\AppData\Local\Temp`.

To determine where the `\Temp` directory is for the logged on user, run the following command in Windows Command Prompt: `ECHO %Temp%`.

Install program does not prompt for location to install to

When you install Tableau Server for the first time, you will be prompted for the location you want to install to. *If you do not see this prompt, you may have leftover files or directories from a previous installation, even if you uninstalled Tableau.* To completely remove all traces of Tableau version 2018.2 or later, run the `tableau-server-obliterate.cmd` script, then

restart the computer and try the install again. If the previous installation was a version earlier than 2018.2, manually delete all Tableau related folders before rerunning the install program.

Important: If you created a backup of Tableau (<file>.tsbak) you want to keep (for example, to restore to your new installation), copy that file to a safe location on another computer to guarantee it is not removed when you clean up your Tableau computer.

Install program does not restart Windows

When you install Tableau Server the Setup program may prompt you to restart Windows at the end of the installation. In certain cases, clicking **Restart** does not restart the computer. This can happen when a 3rd Party component installer is requesting a restart of Windows.

If clicking **Restart** does not restart Windows, complete the installation by manually restarting Windows.

TSM Install fails with "initialization failed" error

If you attempt to install Tableau Server and the installation fails with this error:

```
Tableau server initialization failed  
See install log at C:\ProgramData\Tableau\Tableau Server\logs
```

This may be related to a permissions issue on your computer. The user is signed into Windows and installing Tableau must have administrator permissions to the C drive, to C:\Windows, and C:\Windows\System32 folders, and to the cmd.exe file. This is true even if you are not installing Tableau on the C drive.

For more information, see the [Tableau Knowledge Base](#).

TSM Initialize screen does not display

When installing or upgrading Tableau Server, if the browser opens but nothing displays, you may need to add the hostname to the trusted sites list. Alternatively, clear the browser cache or use a different browser. For more information, see the [Tableau Knowledge Base](#).

Tableau Server on Windows Help

Unable to log into TSM or Tableau Server (sign in screen redisplay after entering credentials)

Using Internet Explorer or Edge, if you enter your credentials into the TSM or Tableau Server sign-in screen and the page redisplay without signing you in, verify that the hostname or domain in your URL does not include an underscore (_). If the hostname or domain of the Tableau Server computer includes an underscore (_) Internet Explorer or Edge browsers will not set a cookie, so the page will redisplay without signing you in. To work around this, use "localhost" or the IP address of the computer in the URL. For example: `https://-localhost:8850`.

Note: If you are using AD for your Tableau Server identity store, you may be locked out of Active Directory if you try to sign in too many times.

For more information, see the [Tableau Knowledge Base](#).

Multiple install attempts fail

If you attempt to install Tableau Server and the install fails, any subsequent installation attempts are likely to fail unless you run the `tableau-server-obliterate.cmd` script to clean Tableau off the computer.

Important: You must run the `tableau-server-obliterate.cmd` script from a 64-bit command prompt. For example, run `cmd.exe` in the `C:\Windows\System32` folder. If you run the script from a 32-bit command prompt, the script will not completely remove Tableau, and subsequent installations may fail. To determine if you are running a 64-bit command prompt, type `echo %processor_architecture%` in your command window. If the result includes "64" (AMD64 for example), the command prompt is a 64-bit prompt. If the result includes "x86" you are running a 32-bit prompt. For more information, see the appropriate Microsoft documentation for your versions of Windows.

A failed install attempt can leave the computer in a state that causes subsequent attempts to also fail with errors that don't seem directly related to a previous install attempt.

To fix this problem, run the `tableau-server-obliterate.cmd` script to clean up any left over remnants of the previous install attempt and then restart the computer. For more information, see [Running the tableau-server-obliterate script](#).

Important: If you created a backup of Tableau (<file>.tsbak) you want to keep (for example, to restore to your new installation), copy that file to a safe location on another computer to guarantee it is not removed when you clean up your Tableau computer.

Obliterate script generates error: "refresh-environment-variables.cmd" is not recognized as an internal or external command

If you use Control Panel to uninstall Tableau Server and then run the `tableau-server-obliterate.cmd` script to completely remove Tableau from your computer, the script may generate an error about the refresh-environment-variables. This occurs because a second script called by the obliterate script was not moved to the temp directory. You can ignore this error.

Install fails due to hardware requirements

Tableau Server cannot install if the computer you are installing on does not meet the minimum hardware requirements. The requirements apply to all computers on which you are installing Tableau Server. For details on minimum hardware requirements, see [Minimum Hardware Requirements and Recommendations for Tableau Server](#).

Install or upgrade fails due to CPU requirements

Beginning in version 2020.4.0 Tableau Server requires CPUs that support SSE4.2 and POPCNT instruction sets. You cannot install or upgrade Tableau Server 2020.4.0 or later on computers that have CPUs which do not support these instruction sets.

You may see this error message when installing a new installation, or in preparation for upgrading an existing installation:

Tableau Server on Windows Help

Your computer's processor doesn't meet the minimum requirements that Tableau requires to install the software. If you are using a VM, make sure Processor compatibility mode is off.

The SSE4.2 and POPCNT instruction sets have been common for more than 10 years and most newer CPUs support them, but if you get an error related to processor minimum requirements when attempting to install or upgrade Tableau Server on a Virtual Machine (VM), Processor compatibility mode may be enabled on the VM. To successfully install or upgrade Tableau on a VM, make sure the Processor compatibility mode is turned off.

Common Tableau Server Upgrade Issues

Upgrade logs location

By default the upgrade log, `app-upgrade.log`, is written to `C:\ProgramData\Tableau\Tableau Server\logs`.

Error: Failed to establish a connection with Active Directory

Beginning with Tableau version 2021.2, Tableau Server no longer allows insecure connections with Active Directory. If your current instance of Tableau Server is communicating with Active Directory over a non-encrypted channel, upgrade will fail.

To resolve this issue follow one of the steps below:

- Investigate and resolve the failed secure connection. See the Microsoft topic, [LDAP Over SSL Connection Issues](#).
- Run the following commands to allow an insecure connection on your current version of Tableau Server before you upgrade:

```
tsm configuration set -k wgserver.domain.allow_insecure_connection -v true --force-keys  
  
tsm pending-changes apply
```

After upgrade completes, we recommend securing the channel and then setting this option to `false`.

Note: By default (when `wgserver.domain.allow_insecure_connection` is set to `false`), Active Directory group synchronization will fail if the communication channel with Active Directory is not encrypted.

Maps do not display or display incompletely after upgrading

Beginning with Tableau version 2019.2, the internet access requirements changed for maps. If you are upgrading from version 2019.1.x or earlier to version 2019.2.x or later, and maps are not displaying as expected, confirm that your environment is configured to allow access on port 443 to `mapsconfig.tableau.com` and `api.mapbox.com`.

In version 2019.1.x or earlier, access was necessary to `maps.tableausoftware.com`.

For more details on internet access requirements, see [Communicating with the Internet](#).

Upgrade script error: "Tableau Server Version change validation failed."

When upgrading, if you run the `upgrade-tsm` script from the `scripts.<version_code>` directory for the earlier version, the upgrade will fail with an error:

```
Tableau Server Version change validation failed.
Tableau Server <version> is already installed.
```

If you get this error, change to the `scripts.<version_code>` directory for the version you just installed and run the script from there.

Upgrade multi-node, initializing additional node fails with "Enter your credentials again" error

If you attempt to initialize an additional node when upgrading Tableau Server and see this error:

Tableau Server on Windows Help

Enter your credentials again. The credentials you enter must provide administrative access to the computer where you generated the configuration file.

this is an indication that the node is unable to connect to or communicate with the initial node.

This can happen for multiple reasons:

- The credentials you entered are not valid or you mistyped them. The credentials must be for a user who has administrative permissions on the computer where Tableau Server was first installed. You do not need to use the credentials of the user who created the bootstrap file but doing so will ensure you are using valid credentials.
- The local firewall of the computer you are trying to add is not allowing communication to the initial node. For more information, see [Local firewall configuration](#).

Upgrade stops or fails at 12%, 78%, or 92%

In certain instances, the upgrade-tsm.cmd script can stall or fail partway through. The cause of this depends on what point the script stops.

- If the script stalls at 12% or 78% this could be due to a known issue (fixed in version 2018.2.1) related to upgrading while SSL is enabled. For more information, see the [Tableau Knowledge Base](#).
- If the script stalls at 92%, while executing the "Enabling the services required for indexing" step, this can be due to problems starting Tableau Services. You can restart Tableau Server Service Manager manually to work around this issue. For details, see the [Tableau Knowledge Base](#).

Upgrading fails due to lack of disk space

If there is not enough disk space for the Tableau Server Setup program to run and do the upgrade, the installation will fail. The amount of disk space required will depend on the size of your repository database and the number and size of your extracts.

Note: When upgrading from a pre-TSM version of Tableau Server (a version earlier than 2018.2.0), the uninstall of Tableau creates a server backup file in the data directory. This backup file has a `.tsbak` extension and is required for the upgrade. *After* you upgrade successfully, you can safely delete this file to free up space (make a copy on a computer that is not part of your Tableau Server installation in case you need the file for any reason). Do not delete this file until you have completed the upgrade and know it is working.

To free up disk space:

1. Create a log archive snapshot using the `tsm maintenance ziplogs` command.

After you create the ziplogs file, save it to a safe location that is not part of your Tableau Server installation.

2. Clean up unnecessary files using the `tsm maintenance cleanup` command. For more information, see [Remove Unneeded Files](#).

Upgrade fails on RebuildSearchIndex job

Beginning with version 2020.1.x, the final step in an upgrade is to rebuild the search index. At this point all services have been upgraded, so if this job fails, you can manually reset the search server by running the `tsm maintenance reset-searchserver` command. You do not need to obliterate and start over.

The error will be:

```
An error occurred while rebuilding search index.
```

To reset the search server :

1. On the initial node, open a command prompt as administrator.

This must be a new command prompt because the upgrade script updates system

environment for the new version.

2. Rebuild the search index using the `tsm maintenance reset-searchserver` command.

Upgrade fails on 2022.1 and later

After upgrading Tableau Server 2022.1 (or later), restoring a Tableau Server backup as part of your upgrade process can cause the following error:

“The backup cannot be restored because Tableau Server uses the new identity service tables by default.”

This issue occurs because Tableau Server 2022.1 (and later) uses an identity schema that is different from the identity schema used by the backup. To resolve this issue, see [Troubleshoot Issues with the Identity Migration](#).

Upgrade fails on 2020.4.0 or later

Beginning with version 2020.4.0, the Checkpoint Upgrade feature allows you to retry a failed upgrade. In general, this is most useful for experienced server administrators and IT professionals who are comfortable with Tableau Server log files and are willing to search through them. But the feature can help in all failed upgrades because it allows you to rerun the `upgrade-tsm` script, and the script is run from the last successful step, saving time. For those with experience, it may be possible to identify problems like disk space problems, or permissions issues, correct them, and rerun the upgrade.

If you are upgrading to version 2020.4.0 or later and the upgrade fails, the following steps may help you to complete the upgrade:

- Rerun the `upgrade-tsm` script. Upgrade failures are sometimes a result of timeouts during the upgrade process, and rerunning the script can allow the upgrade to get beyond intermittent or occasional timing issues. This is also a step that is safe to do, and easy. Rerunning the script will do no harm, and at worst, the upgrade will fail again at the same point, but without needing to go through any previous steps.

The script is located in the `\scripts` directory:

By default,

```
C:\Program Files\Tableau\Tableau Server-
\packages\scripts.<version_code>\upgrade-tsm.cmd
```

If your Tableau Server upgrade isn't successful when you rerun the upgrade-tsm script, and you are comfortable with Tableau Server logs, you can take these additional troubleshooting steps:

- Look at the output of the script in the command window (rerun the script if you no longer have the command window open). You need to run the script in a command window with administrator access. Useful error messages may help you identify the cause of the upgrade failure and give you some ideas for how to correct the issue.
- Look in the `app-upgrade.log` file. Any errors that are displayed at the command line will also appear in the `app-upgrade.log` file, often with more details.
- Look in the `tabadmincontroller.log` file. Upgrade problems that aren't easily identifiable in the above two instances are likely the result of an issue in a job. The `tabadmincontroller.log` file may have more information that helps you diagnose the issue.

Note: For information about log file locations, see [Tableau Server Logs and Log File Locations](#).

Upgrade fails due to permission problems with the backup/restore file location

With versions of Tableau Server before 2022.1.0, if the file location for the backup/restore file does not have the correct permissions, the upgrade script will fail with an error about not being able to read the backup file or not being able to restore the repository.

Beginning with version 2022.1, the upgrade script confirms the permissions of file location for the backup/restore file before starting the upgrade so the file can be written to and read from the location during the upgrade to the new version of Tableau Server.

Required permissions for the backup/restore file location:

Tableau Server on Windows Help

- NetworkService: read/write/execute permission
- Run As service account: read/write/execute permission

The errors will be similar to these:

```
The runas user does not have permission to read the backup file:
<backup/restore basefilepath>.
```

```
Repository restore failed.
An error occurred during installation.
An error occurred while restoring repository.
```

The location used by TSM for backup and restore is defined by the `base-filepath.backuprestore` configuration key and has a default that the installation program sets up with correct permissions, but these may be impacted by organization IT rules or if you change the location to one you have created yourself. A new command available starting in 2022.1 allows you to check the permissions on the backup/restore file location immediately after creating it, to avoid any permission-related problems. For details about that command, see `tsm maintenance validate-backup-basefilepath`.

For details about the backup/restore file path, see [tsm File Paths](#).

Common Settings Import Issues

Import of settings file causes "not present on any node" validation error due to missing services

If you are upgrading by installing a new version of Tableau Server and importing a settings file from an earlier version, you may encounter topology validation errors when running the `tsm settings import` command.

This can happen when you export a settings file from an older version of Tableau Server and import it into a new version, and new services have been added to Tableau between the two versions.

Errors will be similar to this (the specific service may be different):

```
c:\Users\mytableau\Desktop>tsm settings import -f 20183-export.json
```

Pending topology set.

There are 1 topology validation errors/warnings.

Service 'elasticsearch' is not present on any node in the cluster.

Service: Elastic Server

To resolve this issue, add any missing services to Tableau Server:

1. For any service that generated a validation error, add the service with an instance count of 1.

For example, if the Elastic Server is not present in the cluster, set the process instance count to 1 using the service name that appears in the first line of the validation error message:

```
tsm topology set-process -n node1 -pr elasticsearch -c 1
```

Repeat this step for each service that results in an error.

2. When you have no more warnings or errors, apply the pending changes:

```
tsm pending-changes apply
```

Your settings should be imported successfully.

Import of settings file causes "configuration value you specified does not match" error

If you are installing a new version of Tableau Server and import a settings file from an earlier version, you may encounter configuration validation errors when running the `tsm settings import` command. These can occur when a settings file includes a configuration value that has since been removed from Tableau.

The error will look similar to this (the configuration key may be different):

```
c:\Users\mytableau\Desktop>tsm settings import -f 20183-export.json
Configuration error: At least one configuration value you specified
does not match a known configuration key. This applies to the fol-
lowing keys: '[features.TsmConfigFileService]'
Use this parameter to override unknown key error: --force-keys
```

To resolve this issue, edit the settings file you are importing to remove the reference to the configuration key or keys in the error:

1. Copy the JSON settings file and save the copy for backup.
2. Open the JSON settings file in a plain text editor.
3. Locate and delete the entire line that includes the key. In this example, `features.TsmConfigFileService:`

```
"configKeys" : {  
  "config.version" : 19,  
  "tabadmincontroller.port" : "8850",  
  "endpoints.enabled" : false,  
  "endpoints.health.enabled" : true,  
  "features.TsmConfigFileService" : true,  
  "tableau_projects.language" : "en",
```

The above is an example of a small section of an exported settings file and is not intended to represent the entire contents of the file.

4. Save the settings file and import it again.

You may encounter additional errors related to topology validation. For information about solving those errors, see [Import of settings file causes "not present on any node" validation error due to missing services above](#).

"You cannot directly modify instances of the Coordination Service" error

This error can occur in two situations:

- When you import a Tableau Server settings file into an installation that has a different Coordination Service topology than the settings file does
- When you attempt to configure the Coordination Service using the `tsm topology set-process` command

If you see this error after importing a settings file:

The Tableau Server settings file has a different Coordination Service topology than the target server does. This can happen if you are upgrading Tableau Server by installing a new version and importing a settings file from an earlier version. If you have not explicitly deployed a Coordination Service ensemble on the target server, it has a single instance of Coordination Service, on the initial node.

To correct this error you can take either correct the mismatch from the command line, or by editing the settings import file. You can also discard all pending changes, deploy the Coordination Service on the target computer to match the settings in the import file, and reimport the settings file.

To correct the mismatch from the command line, for each node that generates an error, use the `tsm topology set-process` command to revert the instance count of Coordination Service.

1. Run the `tsm pending-changes list` command. The output shows you which nodes have changes.
2. Find the node or nodes where the Coordination Service count is changed.

For example, if the settings file had a Coordination Service instance on node2, but the target system did not have any Coordination Service instance on that node, the count for node 2 would show as changed from 0 to 1 by the import of the settings file:

```
C:\Windows\system32>tsm pending-changes list
Configuration
There are no pending configuration changes.
Topology
node2:
    Coordination Service
        New Instance Count:1
        Old Instance Count:0
```

3. Use the `tsm topology set-process` command to set the count back to the "Old Instance" value.

For the example above:

```
tsm topology set-process -n node2 -c 0 -pr "Coordination Service"
```

4. Once you have reset any Coordination Service instance count that was changed, apply pending changes:

```
tsm pending-changes apply
```

If you see the error when setting the process count for Coordination Service manually:

This error can also occur if you attempt to update the Coordination Service directly, using the `tsm topology set-process` command instead of the `tsm topology` commands for managing the Coordination Service. If you tried this:

1. Use the `tsm pending-changes discard` command to discard the pending changes.
2. Use the correct commands for configuring the Coordination Service. For more information, see [Deploy a Coordination Service Ensemble](#) .

Troubleshooting connections to TSM

Unable to connect to TSM

If you are able to connect to TSM from the computer where you installed Tableau (using `https://localhost:8850` for example), but cannot connect from another computer (using `https://<server-name>:8850`), you may need to configure the local firewall on the Tableau Server computer.

Beginning with version 2018.2 you need to configure the firewall manually. For more information, see [Local firewall configuration](#).

Starting Tableau Server

Tableau Server cannot determine if it fully started

In some instances Tableau Server may report that it could not determine if all components started properly on startup. A message displays: "Unable to determine if all components of the service started properly."

If you see this message after starting, verify that Tableau Server is running as expected by using a `tsm status -v` command.

If the status shows as running ("Status: RUNNING"), then the server successfully started and you can ignore the message. If the status is DEGRADED or STOPPED, see "Tableau Server doesn't start" in the next section.

Tableau Server doesn't start

If Tableau Server does not start or is running in a degraded state, run the `tsm restart` command from a command prompt. This will shut down any processes that are running, and restart Tableau Server.

Reindexing Tableau Server Search & Browse

Problems that can be solved by rebuilding Search & Browse index

Symptoms of an index that needs to be rebuilt include:

- A blank list of sites when a user attempts to log in
- A blank list of projects when a user tries to select a project
- Missing content (workbooks, views, dashboards)
- Unexpected or inaccurate alerts (for example, an "refresh failed" alert on a workbook that does not include an extract)

If you see any of these behaviors, reset and rebuild the Search & Browse index using the `tsm maintenance reset-searchserver` command.

Activating Tableau Server

Tableau Server license activation fails

In some instances Tableau Server license activation may fail. Error messages can range from a very generic one:

- An error has occurred

To more specific messages:

- Function `flxActCommonLicSpcPopulateFromTS` returned error 50030, 71521,
- No license found for 'Tableau Server'

To resolve this issue, try these solutions in the order listed:

Confirm you can access the licensing server

The Tableau licensing service was moved to a new data center on October 6, 2018. This means any environments that required special configuration (static IP safe listing for example) to access `licensing.tableau.com` or `licensing.tableau.com` will need to be updated before you can activate, refresh, or deactivate a Tableau product key.

To test access, type the URL and the port of the licensing server in a browser:

```
https://licensing.tableau.com:443
```

and:

```
https://atr.licensing.tableau.com/_status/healthz
```

If you are able to access the server, a "Test success" message displays for the first server, and an "OK" message displays for the second.

Tableau Server needs to make a connection to the following internet locations for licensing purposes:

- `atr.licensing.tableau.com:443`
- `licensing.tableau.com:443`
- `register.tableau.com:443`
- `o.ss2.us`
- `s.ss2.us`
- `crt.rootca1.amazontrust.com`
- `crt.sca1b.amazontrust.com`
- `crt.sca0a.amazontrust.com`
- `crt.sca1a.amazontrust.com`
- `crt.sca2a.amazontrust.com`
- `crt.sca3a.amazontrust.com`
- `crt.sca4a.amazontrust.com`
- `*.digicert.com`
- `ocsp.*.amazontrust.com`
- `crl.*.amazontrust.com`

Requests to the above domains may be on port 80 or 443. Port 80 is used for certificate validation (revocation, certificate chain, etc). Port 443 is used for SSL connections.

Requests to the `ocsp.*.amazontrust.com` and `crl.*.amazontrust.com` domains are managed by Amazon for certificate revocation information. See [ACM certificate characteristics](#) for more information.

Tableau Server on Windows Help

Verify the date and time

Verify the date and time on the initial Tableau Server computer is correct. If the clock is set to a time and date earlier than the current date, Tableau Server cannot be activated.

Verify FlexNet Licensing Service has started

If the date and time on the Tableau Server computer are correct, verify that the FlexNet Licensing Service is running on the initial Tableau Server computer.

1. On the initial computer, from the Windows Start menu, open **services.msc**.
2. In the Services dialog box, verify that the status of *FlexNet Licensing Service 64* (64-bit) or *FlexNet Licensing Service* (32-bit) is **Started**.

If FlexNet is not listed as **Started**, right-click FlexNet Licensing Service and select **Start**.

If the **Start** option is grayed out, the service may be set to Disabled. To enable the service:

- a. Right-click FlexNet Licensing Service and select **Properties**.
- b. From the **Startup type** drop-down list, select **Automatic**.
- c. Click the **Start** button, and then click **OK**.

Force the product key to be read again

1. On the initial Tableau Server computer, sign in as administrator and open a command prompt.
2. Change to the Tableau Server bin directory. By default this is:

```
C:\Program Files\Tableau\Tableau Server\packages\bin.<version_code>
```

3. Type the following commands:

```
tsm stop  
lmreread
```

```
tsm start
```

Send the contents of trusted storage to Tableau Support

If FlexNet Licensing Services is installed and running but you're still seeing an error, there might be a problem with the Tableau product key information. To resolve this issue, complete the following steps to create a file of the key information located in trusted storage.

1. On the initial Tableau Server computer, sign in as administrator and open a command prompt.
2. Type the following command:

```
serveractutil -view > <machine_name>-LicResults.txt
```

This creates the `<machine_name>-LicResults.txt` file in your current directory. If you don't have write permissions for that location and see an error, change to a location where you do have permission to create a file and run the command again.

3. Contact Tableau Support (<http://www.tableau.com/support/request>) and include the `<machine_name>-LicResults.txt` file that you created.

tabcmd Installation Problems

Installing tabcmd separately

tabcmd is automatically installed on the initial Tableau Server node when you install Tableau Server, but if you want to run it on another computer, you need to download and install tabcmd separately. For details, see [Install tabcmd](#).

Problems installing tabcmd on Linux

tabcmd requires Java 11 to run properly. On RHEL-like systems, this will be installed as a dependency when installing tabcmd. On Debian-like systems, you need to install Java 11 separately if it is not already installed.

As of July 2022, Debian distributions are no longer supported. For more information, see [this Tableau Community post](#).

Java is not installed

If you see errors similar to this when installing tabcmd, confirm that Java 11 is installed on your Linux computer:

```
Cannot find 'java' in your PATH. Install 'java' and make sure it is  
in your PATH to continue.
```

Incorrect version of Java is installed

If you see errors similar to these, confirm that Java 11 is installed:

```
Exception in thread "main" java.lang.UnsupportedClassVersionError:  
com/tableausoftware/tabcmd/Tabcmd : Unsupported major.minor version  
52.0
```

or.

```
*** Uncaught exception NoClassDefFoundError: javax/xml-  
1/bind/JAXBException  
*** See the logs for the stacktrace.
```

Uninstall Tableau Server

Do not uninstall Tableau before upgrading. For details on upgrading, see [Upgrading from 2018.2 and Later \(Windows\)](#).

Beginning with version 2018.2, you can have multiple versions of Tableau Server installed at the same time. This allows you to run most of an upgrade while an existing version is running, and reduces downtime and impact to users. Once you have upgraded, you can uninstall your previous version. Doing this frees up disk space. You do not have to uninstall the previous version.

This article explains how to uninstall previous versions, after you've upgraded to a newer version.

Uninstalling and completely removing Tableau Server

There are two primary "uninstall" scenarios that Tableau Server on Windows supports:

- **Uninstall Tableau Server:** *After you upgrade* to a new version of Tableau Server you can uninstall your previous version to free up disk space. Continue reading for information about uninstalling Tableau.
- **Remove Tableau Server:** If you want to complete remove Tableau Server from a computer, you can use a script provided by Tableau to remove Tableau Server and all related files. *This removes all data as well as server components, so should only be done if you know you want to reset the computer to a pre-Tableau state.* You might need to do this if Technical Support recommends this step when troubleshooting an installation problem. We recommend you create a backup of your data before removing Tableau. Save the backup file to a safe location on a computer that is not part of your Tableau installation. Completely remove Tableau Server without uninstalling any version first. The script will uninstall all existing versions found on the computer. If you have already uninstalled your existing version and now want to completely remove Tableau, you can find the script to do so in a temporary location. For more details, see [Remove Tableau Server from Your Computer](#).

Uninstall a Tableau Server version

When upgrading from one TSM version to another, you must leave the earlier version in place until you have finished the upgrade. *Then* you can uninstall it.

Use Control Panel to uninstall an earlier version of Tableau Server after upgrading. Starting with version 2018.2, you can have multiple versions of Tableau Server installed at the same time. All installed versions are visible in Control Panel, but only one version is running (the running version will generally be the version you upgraded to, but if you have not completed the upgrade process it could be an earlier version). After completing the upgrade you can uninstall your previous version.

Important: Beginning with version 2018.2, uninstalling Tableau Server will not create a backup of your data. As a best practice, always create a backup of your data before upgrading or uninstalling Tableau. This ensures you can reinstall and restore the data if you decide you want to do this. Save the backup to a safe location on a computer that is not part of your Tableau Server installation.

To uninstall a version of Tableau Server:

1. Open Control Panel, click **Uninstall a program**, and locate the version you want to uninstall.

Be sure you select the correct version to uninstall:

- Uninstalling previous versions of Tableau Server does not impact the running version and simply removes unnecessary files from those previous versions.
- **Do not** uninstall the current, running version. Uninstalling the current, running version of Tableau Server stops server and removes server-specific files and folders, but may leave some elements behind. Uninstalling does not create a backup of your repository data.

2. With the Tableau Server version selected, click **Uninstall**.

Remove Tableau Server from Your Computer

Warning: The steps below *completely remove* Tableau Server on Windows, and delete all related data, users, and configuration information. This includes any files in `\temp`. Tableau Server licenses are also deactivated if you include the `-l` option when running the command shown below and the computer is connected to the internet.

As a best practice, copy any backup files you want to save to a location that is not related to Tableau. This will preserve the files when you remove Tableau. You should copy any

backup files to a separate computer for safety, including backup files created when you uninstall Tableau. By default these are created in `C:\ProgramData\Tableau\Tableau Server` with a name similar to `uninstall-2018.1.tsbak`. Saving backup files on a separate computer will allow you to reinstall the version of Tableau Server that created the backup, and have the data contained in the backup, even after running the `tableau-server-obliterate.cmd` script.

If you want to uninstall a particular Tableau Server package to free up disk space (after upgrading, for example), see [Uninstall Tableau Server](#).

As part of the regular installation of Tableau Server, a script is installed that provides you a way to completely remove Tableau and all associated files from your computer. This is something you would only do if you did not care about your Tableau data, configuration, or log files, or if you are working with Tableau Technical Support and need to reinstall Tableau Server after an installation or upgrade attempt fails. The obliterate script will not remove any drivers you installed separately, even those you installed to use with Tableau Server.

The `tableau-server-obliterate.cmd` script is intended for when you want to completely remove Tableau Server from your computer. You might want to do this for a couple of different reasons:

- You no longer want Tableau Server installed on the computer. Use the `tableau-server-obliterate.cmd` script to remove Tableau Server completely. If this is the case, and the computer is connected to the internet, you can include a `-l` option to deactivate the Tableau Server license.
- Troubleshooting Tableau Server installation problems—If you run into issues installing Tableau, you may need to use the `tableau-server-obliterate.cmd` script to completely remove Tableau Server from your computer before reinstalling. Doing this will clean up any older settings or states and allow you to reinstall on a "clean" computer. If you are doing this, you can leave off the `-l` option to preserve

licensing information on the computer. When you omit the `-l` option, you will not need to activate your license when you reinstall Tableau Server.

Important: You must run the `tableau-server-obliterate.cmd` script from a 64-bit command prompt. For example, run `cmd.exe` in the `C:\Windows\System32` folder. If you run the script from a 32-bit command prompt, the script will not completely remove Tableau, and subsequent installations may fail. To determine if you are running a 64-bit command prompt, type `echo %processor_architecture%` in your command window. If the result includes "64" (AMD64 for example), the command prompt is a 64-bit prompt. If the result includes "x86" you are running a 32-bit prompt. For more information, see the appropriate Microsoft documentation for your versions of Windows.

What tableau-server-obliterate does

The intent of the `tableau-server-obliterate.cmd` script is to completely remove Tableau Server from your computer. This includes files, system settings and configurations, and, if you specify, licensing information.

When you run `tableau-server-obliterate.cmd`, the following steps are taken:

- Uninstall is run for all installed versions of Tableau Server (Control Panel uninstall).
- Most contents of the data directory is removed (by default `C:\ProgramData\Tableau\Tableau Server`). Backup and log files are preserved by default. See the section below, "Preserving Tableau Server backup and log files."
- All registry entries related to Tableau Server are removed.
- All server licenses are deactivated if you use the `-l` option and the computer is connected to the internet. This option does not work in offline situations.

Preserving Tableau Server backup and log files

Prior to version 2020.1 of Tableau Server, running the `tableau-server-obliterate` script deleted all content from the Data directory. Beginning with version 2020.1, the default behavior of the `tableau-server-obliterate` script has changed: the script copies and saves Tableau Server backup and log files to the `logs-temp` directory. The default location for the `logs-temp` directory is at `\ProgramData\Tableau\logs-temp`. You can set options on the script to disable this new functionality.

To change the default behavior and to remove backup or log files, include one of the following options when running the `tableau-server-obliterate.cmd` script:

- `-k` Do not copy backups to logs-temp directory.
- `-g` Do not copy logs to logs-temp directory.
- `-a` Do not copy anything to logs-temp directory.

Running the `tableau-server-obliterate` script

You can completely remove Tableau Server from a computer, either preserving the licensing information, or removing the licensing information along with all other aspects of Tableau Server. You might want to preserve licensing if you are going to reinstall Tableau Server on the same computer.

An older version of `tableau-server-obliterate.cmd` may miss files from new versions of Tableau Server. Always run the obliterate script for the version of Tableau Server that is installed on the computer.

To completely remove Tableau Server without removing server licensing

The example script in this procedure also includes the `-a` option to remove Tableau Server backup and log files.

Note: If you plan to reinstall Tableau Server and Activate Tableau Server Using the Authorization-To-Run (ATR) Service, we recommend that you remove licensing information before reinstalling and activating Tableau Server using Server ATR.

1. On the initial node, open a command prompt as administrator.
2. Run the `tableau-server-obliterate.cmd` script:

```
By default: C:\Program Files\Tableau\Tableau Server-
\packages\scripts.<version_code>\tableau-server-obliterate.cmd
-a -y -y -y
```

Note: If you have already uninstalled Tableau Server using Control Panel and now you want to completely remove it, run the copy of the `tableau-server-obliterate.cmd` script located in the `\Tableau Server\temp` folder (by default: `C:\Program Files\Tableau\Tableau Server\temp`). If the script is not in that directory, reinstall the Tableau Server package and then run the `tableau-server-obliterate.cmd` script from the scripts folder (By default: `C:\Program Files\Tableau\Tableau Server-packages\scripts.<version_code>\`).

You can also get a copy of the script from this Knowledge Base article: [Obliterate Script Unavailable](#).

If you have a multi-node (distributed) installation of Tableau Server, run the `tableau-server-obliterate.cmd` script on each node in the cluster.

3. Restart each computer you ran the `tableau-server-obliterate.cmd` script on.

To completely remove Tableau Server and licensing

The example script in this procedure also includes the `-a` option to remove Tableau Server backup and log files.

1. On the initial node, open a command prompt as administrator.
2. Deactivate any active product keys.

```
tsm licenses deactivate -k <product_key>
```

3. Run the `tableau-server-obliterate.cmd` script:

```
By default: C:\Program Files\Tableau\Tableau Server-  
\packages\scripts.<version_code>\tableau-server-obliterate.cmd  
-a -y -y -y -l
```

The `-l` option for the `obliterate` script removes all licensing files from the computer if the computer is connected to the internet. The script first attempts to deactivate any active licenses, but it will remove all licensing information whether or not deactivation was successful. This is why we recommend you run the `tsm licenses deactivate` command before running the `obliterate` script.

Note: If you have already uninstalled Tableau Server using Control Panel and now you want to completely remove it, run the copy of the `tableau-server-obliterate.cmd` script located in the `\Tableau Server\temp` folder (by default: `C:\Program Files\Tableau\Tableau Server\temp`). If the script is not in that directory, reinstall the Tableau Server package and then run the `tableau-server-obliterate.cmd` script from the scripts folder (By default: `C:\Program Files\Tableau\Tableau Server\packages\scripts.<version_code>\`).

If you have a multi-node (distributed) installation of Tableau Server, run the `tableau-server-obliterate.cmd` script on each node in the cluster. You do not need to deactivate licenses on any additional nodes.

4. Restart each computer you ran the `tableau-server-obliterate.cmd` script on.

Help Output for tableau-server-obliterate Script

The following help content is the output when you run the following command:

```
tableau-server-obliterate -h
```

The `./tableau-server-obliterate` script is installed to By default: `C:\Program Files\Tableau\Tableau Server\packages\scripts.<version_code>\`.

Output

```
Remove Tableau Server from this computer.
```

Tableau Server on Windows Help

This script will stop and remove all Tableau Services from this computer. It also removes data and configuration files. It leaves licensing in place. It also preserves logs and backup files, which are moved to a temp directory under the Tableau data folder. You can force removal of these files, and licensing, using optional parameters.

This script is destructive and not reversible. It should only be used to clean Tableau Server from a computer. For multi-node installations, you must run the script separately on each node.

This script must be run as the Administrator.

-y	Required. Yes, remove Tableau Server from this computer.
	Must be specified three times to confirm.
-q	Optional. Quiet mode. Windows only. Do not display progress UI when removing Tableau Server.
-l	Optional. Delete licensing files and data. This command will attempt to deactivate licenses before deleting licensing data. Internet access is required for license deactivation. Offline deactivation is not supported. To deactivate license before removing Tableau Server, run 'tsm licenses deactivate' before running this script.
-k	Optional. Do not copy backups to logs_temp directory.
-g	Optional. Do not copy logs to logs_temp directory.
-a	Optional. Do not copy anything to logs_temp directory.

Migrate

The topics in this section describe how to migrate from Tableau Server to Tableau Cloud. Topics here also cover Tableau Server to Tableau Server migration scenarios.

Looking for Tableau Server on Linux? See [Migrate](#).

Migrate Tableau Server to Tableau Cloud	446
Server to Server Migrations	457

Migrate Tableau Server to Tableau Cloud

For information about migrating small (less than 100 users) Tableau Server to cloud, see [Tableau Cloud Manual Migration Guide](#).

For information about planning a move to Tableau Cloud, see [Tableau Blueprint: Move Tableau to Cloud](#).

Technical Considerations for Migrating from Tableau Server to Tableau Cloud

This topic covers most of the technical considerations that may arise in a migration from Tableau Server to Tableau Cloud. It's written for the administrators that currently manage Tableau Server and who are considering a migration to Tableau Cloud. We recommend that you review this topic as a primary step in your migration plan. Additionally, work with your account team to understand if a migration makes sense for your organization.

The topic reflects the product capabilities in Tableau Server 2023.1.

For additional information and to initiate a migration to Tableau Cloud, visit the [Tableau Cloud Migration](#) site on Tableau.com.

Summary outline

This topic is organized into four major areas that are familiar to Tableau administrators. The following tables show a summary feature comparison between Tableau Cloud and Tableau Server within each major area. For more information on a given feature, see the corresponding section later in this topic.

Security, administration, and governance		
	Tableau Cloud	Tableau Server
Compliance	See Salesforce Compliance portal. Access to this site may require permission from your account manager.	Managed by customer
Hosting and upgrades	Managed by Tableau	Managed by customer
Site level administration	Single site default	Managed by customer
Telemetry data	Limited	Managed by customer
Observability data	Admin Insights with Activity Log	Managed by customer with repository access and Activity Log
Availability	99.9% with SLA for Premium Support customers	Managed by customer

Data Connectivity		
	Tableau Cloud	Tableau Server
Files	Supported	Supported
Applications and databases	Supported, with database-	Supported

	specific limitations	
Custom connectivity	Limited support	Supported
Cube data sources	Not supported	Supported

User management and licensing		
	Tableau Cloud	Tableau Server
Licensing	Internal: role-based External: role and usage-based	Internal: role and core-based External: role and core-based
SSO	Supported	Supported
Active Directory, Kerberos, LDAP directory	Not supported	Supported
Automated user and group management	Okta, OneLogin, Azure AD, and custom tooling	Active Directory, LDAP

Extensibility and external integrations		
	Tableau Cloud	Tableau Server
Automated tooling through APIs	Supported	Supported
R and Python integration	Supported	Supported
Embedding	Supported	Supported
Customization	Limited support	Supported

Security, administration, and governance

Security and compliance

Make sure Tableau Cloud security certifications meet your organization's requirements. Tableau Cloud is compliant with ISO 27001/27017/27018 and SOC 2/3 and adheres to data privacy requirements such as those outlined in GDPR. To see a complete and up-to-date list of certifications go to the [Salesforce Compliance](#) portal. Access to this site may require permission from your account manager.

Additionally, Tableau Cloud and Salesforce adheres to the strictest standards for regional data security and privacy. Customer data never leaves the region in which it is hosted. Salesforce adopts a Shared Responsibility Model. In this model, we work with you to ensure that all the proper security and compliance controls are enabled by Salesforce and your organization.

Hosting and upgrades

Tableau hosts and manages Tableau Cloud for customers. Tableau Cloud is always running the latest version of Tableau. Major upgrades are completed with zero downtime. Routine maintenance (activities like upgrades, backups, performance tuning, etc.) is performed to minimize downtime. In the case where downtime is required, maintenance occurs during pre-communicated windows. For more information about the Tableau maintenance schedule and how to sign up for maintenance notifications from Tableau Trust, see [Tableau Cloud System Maintenance](#).

Tableau Cloud is run in Amazon Web Services. You can choose to deploy your site in any of the AWS Regions listed [here](#).

Tableau takes daily backups of the environment for Disaster Recovery. However, these backups are for the purpose of restoring the system as a whole. Customers are responsible for maintaining backups of any files they want to recover if they're removed or deleted from Tableau Cloud.

Site level administration

By default, Tableau Cloud deployments provide a single Site for deploying Tableau to your users. A single site model simplifies administration of the environment while allowing comprehensive governance scenarios as recommended in [Blueprint](#).

To ensure consistent performance across the platform, Tableau Cloud restricts sites with site capacity limits. See [Tableau Cloud Site Capacity](#) for a list of capacity types and associated allowances. The capacity restrictions include limits for overall storage and for tasks that you may perform on the site. You can evaluate if any of your use cases would be impacted by these limits by connecting to the Tableau Server repository and comparing usage to the site capacity limits. For more information about connecting to the repository, see [Collect Data with the Tableau Server Repository](#).

Observability data

In Tableau Cloud, you can't connect directly to the Tableau Server repository database. Instead, Site Admins have access to a Project called Admin Insights that contain pre-built observability dashboards and data sources. See [Use Admin Insights to Create Custom Views](#). Admin Insights help you to understand usage, performance, licensing, user management and more. You can also use the provided data sources to build custom reports or take advantage of Accelerators built on this data. For an example, see the [Dashboard Load Times Accelerator](#). Default data retention in Admin Insights is 90 days. With Advanced Management you receive an extended retention period of 365 days and get access to [Activity Log](#) for more detailed observability data.

Availability

Tableau Cloud offers a service level agreement (SLA) that guarantees monthly service availability of 99.9%. We provide this level of service to all Tableau Cloud customers. However, in the unlikely event availability falls short of 99.9%, only those customers subscribed to Premium Support for Tableau Cloud are eligible for a service credit on their account.

Tableau Cloud customers who subscribe to Standard Support or Extended Support benefit from the SLA because Tableau maintains 99.9% availability across all Tableau Cloud

deployments. However, Standard and Extended Support customers can't request service credits if Tableau Cloud fails to meet 99.9%.

Learn more about Technical [Support Services](#) and [Premium Support](#) for Tableau Cloud.

Data connectivity

Where your data resides determines which of the two connectivity options you use with Tableau Cloud:

- Tableau Cloud can directly connect to the cloud data sources listed below. For direct connections, some databases require authorizing Tableau Cloud to access these data sources before you connect. See [Authorize Access to Cloud Data Published to Tableau Cloud](#).

Supported Tableau Cloud connectors

Alibaba AnalyticsDB for MySQL‡	Exasol‡	OData‡
Alibaba Data Lake Analytics‡	Google BigQuery*‡	OneDrive*‡
Alibaba MaxCompute‡	Google Cloud SQL (MySQL compatible)‡§	Oracle‡
Amazon Athena‡	Google Drive‡	Pivotal Greenplum Database‡
Amazon Aurora for MySQL‡	Hortonworks Hadoop Hive	PostgreSQL‡
Amazon EMR Hadoop Hive‡	IBM DB2‡	Presto‡
Amazon Redshift‡	Impala‡	Qubole Presto‡
Apache Drill‡	Kyvos‡	Salesforce‡
Azure Data Lake Storage Gen2‡		SAP HANA (for virtual connections only)‡

Azure Synapse Analytics (SQL Server compatible)	MariaDB‡	SharePoint Lists‡
Box‡	Microsoft Azure SQL Database‡	SingleStore (formerly MemSQL)‡
Cloudera Hadoop‡	Microsoft Azure Synapse Analytics‡	Snowflake‡
Databricks‡		Spark SQL‡
Datorama by Salesforce‡	Microsoft SQL Server‡	Teradata**‡
Denodo‡	MongoDB BI Connector‡	Vertica‡
Dremio by Dremio‡	MySQL‡	
Dropbox*‡		
Esri Connector‡		

*For more information about using OAuth 2.0 standard for Google BigQuery, OneDrive, and Dropbox connections in Tableau Cloud, see [OAuth Connections](#).

**Teradata web authoring currently doesn't support query banding functionality. See [Teradata](#) for details.

‡Supports virtual connections if you have Data Management. See [About Virtual Connections and Data Policies](#) in the Tableau Cloud help for details.

§Tableau Cloud doesn't support SSL using Google Cloud SQL.

- For data that is stored on-premises or in a private cloud network, you can deploy Tableau Bridge. For a list of all the connectors that Tableau Bridge supports and doesn't support, see [Connectivity with Bridge](#).

Files

Tableau Cloud supports various file types. Files hosted on cloud platforms like Google Drive, Dropbox, Box and S3 can use Tableau Cloud direct connectors to support both live and

extract connections. Tableau Bridge supports file-based data connections for extracts, but doesn't support live connectivity to file-based data.

Applications and databases

Tableau Cloud supports most of the same Connectors that Tableau Server supports, but there are some differences. Some databases require specific configuration to enable direct Tableau Cloud connectivity. See [Allow Direct Connections to Data Hosted on a Cloud Platform](#).

Tableau Cloud and Tableau Bridge don't support authentication to a database using Kerberos.

Custom connectivity

Tableau Cloud is designed to use the same database Connector for every Tableau Cloud customer and therefore doesn't support customer-specific connectivity solutions. The two notable exceptions are the Hyper API and Tableau Bridge, which can be used to extend or customize your connectivity. The Hyper API can create extracts that can be published to Tableau Cloud. Tableau Bridge can be used to extend some connectivity options, for example, ODBC, JDBC, and Web Data Connectors. See [Connectivity with Bridge](#).

You can't customize connectivity with Connector SDK (.taco) on Tableau Cloud or with Tableau Bridge.

If you're using Virtual Connections as a part of the Data Management offering there may be differences specific to your desired connector. Verify that Tableau Cloud or Tableau Bridge supports your scenario.

Cube data sources

Tableau Cloud doesn't support Cube Data Sources. Instead, we recommend that you connect directly to the underlying database that the cube is built on top of for greater flexibility in your analysis.

Data prep

Tableau Bridge doesn't support running Tableau Prep Flows with Prep Conductor. Instead, follow the process in the KB article, [How to Run Tableau Prep Conductor Flows with On-](#)

[Premises Data in Tableau Cloud](#), to automate data preparation.

Licensing and user management

Licensing

Tableau Cloud supports licensing with subscription role-based plans. Learn more at the [Tableau Pricing](#) page. To eliminate key management tasks, Tableau Cloud defaults to licensing users with login-based license management ([LBLM](#)). Legacy perpetual licenses and server core-based licensing aren't supported.

Tableau Cloud doesn't offer a "Guest" user. However, connected applications can be used to provide content for broader usage within your organization. See [Use Tableau Connected Apps for Application Integration](#).

If you're licensing Tableau Cloud for users outside of your organization, usage-based licensing for those external use cases is available. See [Raise Revenue and Lower Costs with Usage-Based Licensing for Tableau Embedded Analytics](#).

Single sign-on

Tableau Cloud supports single sign-on (SSO) through both SAML and OIDC. Direct integrations with Okta, Azure AD, One Login, Salesforce, PingOne, and more are supported.

All users accessing Tableau Cloud are required to utilize multi-factor authentication (MFA) to authenticate into Tableau Cloud.

If you aren't using an SSO provider, you can use Tableau Cloud's built-in authentication type, TableauID with MFA. You can also create custom solutions with SAML or use [Connected Applications](#) for embedded solutions.

For more information, see the [Authentication](#) section in Tableau Cloud help.

Active Directory, Kerberos, and LDAP

Tableau Cloud doesn't support direct integration with Active Directory. However you can [configure SAML with Azure AD](#), to integrate with Tableau Cloud.

Additionally, most IdPs have an Active Directory integration that would suffice for authentication with Tableau Cloud. For an example, see [Active Directory integration \(Okta\)](#).

Tableau Cloud doesn't support Kerberos authentication or using LDAP as an Identity Store.

Automated user and group management

Tableau Cloud uses System for Cross-domain Identity Management (SCIM) for automating the exchange of user identity information. There are several IdP-specific configurations available in Tableau Cloud. See [Automate User Provisioning and Group Synchronization through an External Identity Provider](#).

The [Tableau REST API](#) and [tabcmd 2.0](#) supports many user and group automation tasks.

Tableau Cloud doesn't support direct integration with Active Directory for user or group provisioning.

Extensibility and external integrations

Automated tooling

Tableau Cloud supports REST APIs, Javascript APIs, Metadata APIs, Dashboard APIs, Webhooks, and embedding in HTML pages for authenticated users. See [Tableau Developer Tools](#) for more information.

We recommend that you verify your use cases prior to a migration.

There are some differences to be aware of as you plan your automated tooling strategy for Tableau Cloud:

- Tableau Server supports REST APIs for server-level administration. Tableau Cloud supports site-level administration.
- Tableau Server supports a global list of Web Data Connectors. Tableau Cloud requires using Bridge to run extract refreshes for Web Data Connectors.
- The connectors on the Tableau Exchange are only supported by Tableau Server.

APIs supported by Tableau Cloud are optimized for authentication with Tableau personal access tokens (PATs). Plan on refactoring your tooling to use PAT authentication as part of your migration to Tableau Cloud. See [Personal Access Tokens](#).

Extensibility

Tableau Cloud supports analytics extensions with both R and Python. See [Configure Connections with Analytics Extensions](#). However, Tableau Bridge doesn't support analytics extensions, so these extensions are only compatible with data sources that don't require Tableau Bridge.

Tableau Cloud doesn't support [R or Python script steps in a Prep flow](#) authored or published to Tableau Cloud.

Embedding

Tableau Cloud supports embedding Tableau into other applications. It supports the Embedding API, various SSO options, and Tableau REST API for user and content management.

There are two main differences for embedding with Tableau Cloud vs Tableau Server:

- Tableau Cloud supports both a subscription role-based licensing model or a usage-based licensing model for embedding scenarios.
- Tableau Cloud uses a single-tenant model. To ensure data separation, you can use a number of different methods. The data separation strategy you use will be determined by your business needs and embedding solution. The following Tableau Cloud help topics provide more information:
 - [Use Projects to Manage Content Access](#)
 - [Use Tableau Connected Apps for Application Integration](#)
 - [Manage Site User Visibility](#)
 - [Permissions](#)

Customizations

Tableau Cloud allows you to customize some aspects of the user experience like language, locale, custom logos and custom project images. See [Customize the Site and Content Settings](#).

Tableau Cloud doesn't support custom URLs, custom fonts, or custom welcome banners.

Server to Server Migrations

The topics in this section provide information on migrating between hardware, operating system, and public cloud platforms for Tableau Server.

To migrate a site from one Tableau Server to another, see [Export or Import a Site](#).

To copy or migrate content between Tableau Server projects using the Tableau Content Migration Tool, see [About Tableau Content Migration Tool](#).

Migrate to New Hardware

Use the following procedure to migrate Tableau Server from one computer to another. You might do this if you are upgrading the computer hardware that Tableau is running on.

Specifically, these steps describe how to move Tableau Server data from your in-production computer to a new computer where Tableau Server is installed. Before you start, make sure you have followed the steps in [Preparing for Upgrade](#), including creating a backup and gathering any assets that require manual actions. For details, see [Perform a Full Backup and Restore of Tableau Server](#). You'll need these to restore your Tableau Server data and configuration.

Important: If you perform Blue/Green upgrades or manually upgrade Tableau Server 2021.4 (or earlier) using the [tsm maintenance \(backup and restore\)](#) method, you must enable `legacy-identity-mode` before you can restore to Tableau Server 2022.1 (or later). For more information, see [Troubleshoot Issues with the Identity Migration](#).

You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

1. Deactivate your product key on your original installation of Tableau Server. You need to do this so you can activate it on the new computer. For more information, see "Tableau Server product key activation" below.
2. Install Tableau Server on the new computer, activate your license, configure initial settings, and create your admin user. For details, see [Install and Configure Tableau Server](#).
3. Copy your backup file *.tsbak* to the folder location specified by the `base-filepath.backuprestore` variable. By default this is: `C:\ProgramData\Tableau\Tableau Server\data\tabsvc\files\backups\`.

Note: You can change the location for the backup file. For more information, see [tsm File Paths](#).

4. Next, stop Tableau Server:

```
tsm stop
```

5. Restore your in-production data to your new Tableau Server installation using the `tsm maintenance restore` command:

```
tsm maintenance restore -f <filename>
```

where `<filename>` is the name of the *.tsbak* file you copied in step 3.

For more information about restoring Tableau Server data, see [Restore from a Backup](#).

6. Start the server:

```
tsm start
```

7. **Distributed installations only:** Install Tableau Server on the new computers you want to add to your new Tableau Server cluster. See [Install and Configure Additional Nodes](#) for steps.
8. If you have not deactivated your product key on the old computer, do that after you test your new Tableau Server installation and confirm that it's ready for production. For details, see ["Tableau Server product key activation"](#) below.

Note: If you do not have an internet connection, you are prompted to create an off-line activation file to complete the deactivation process. See [Activate Tableau Server Offline](#) for steps.

Tableau Server product key activation

You can activate the same Tableau Server product key up to three times. This allows you to test Tableau Server (in a sandbox or QA environments, for example), as well as use Tableau in production. To maximize your activations, you should deactivate your product key when you remove Tableau Server from a computer, unless you will be reinstalling Tableau on the same computer. Doing this gives you the opportunity to use the activation on a different computer. For example, if you move Tableau Server from one computer or VM to another, deactivate the product key, then remove Tableau from the original computer. When you install Tableau on the new computer, you can activate the key there without any conflict. If you use role-based licensing, be sure to activate a Creator or Explorer key or you may lose administrator access to Tableau. If you are removing Tableau Server to reinstall it on the same computer, you don't need to deactivate the key. Tableau will use the key when reinstalled. For example, if you are moving Tableau from one drive on a computer to a different drive on the same computer. For information on how to deactivate a product key, see [tsm licenses deactivate](#).

Migrate Tableau Server from an On-Premises Computer to a VM in the Cloud

You can migrate Tableau Server from a computer in your data center to a virtual machine (VM) in the cloud. As a part of this migration, you'll need to move various Tableau Server data and configuration settings from your on-premises computer to a VM in the cloud where Tableau Server is installed.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

Prerequisites

Before you migrate Tableau Server from an on-premises computer to a VM in the cloud, be sure to review the following prerequisites:

- Have an account and an environment set up on your cloud provider. For more information, see:
 - [Install Tableau Server on Amazon Web Services](#)
 - [Install Tableau Server on the Google Cloud Platform](#)
 - [Install Tableau Server on Microsoft Azure](#)
 - [Install Tableau Server in the Alibaba Cloud](#)
- Read [Preparing for Upgrade and Back up Tableau Server data](#) to prepare for the migration.

To migrate Tableau Server to a VM in the cloud

1. Ensure that there are no background tasks running, such as, extract refreshes, workbook publishing, etc. When Tableau Server is idle, note any data source connection

types in use so that you can install the appropriate drivers on the new Tableau Server on the VM in the cloud.

2. Stop Tableau Server. At a command prompt, type:

```
tsm stop
```

3. After Tableau Server is stopped, make a complete backup, following the steps in [Preparing for Upgrade](#) and [Back up Tableau Server data](#). The backup is what you will use to restore your Tableau Server data. You'll use this backup to restore your Tableau Server data on the VM in the cloud.
4. Move the backup off the server and store the backup securely. For example, you can store your backup on cloud storage such as Amazon S3, Google Drive, etc.
5. If you are using SSL on the on-premises server, make a copy of the SSL folder. Be sure to note any security rules, for example, firewall rules, ports, etc. to avoid communication issues between different elements of your infrastructure and your new Tableau Server on the VM in the cloud.
6. Remove any DNS entries using the IP address of the on-premises Tableau Server, so you can reassign them to the Tableau Server on the VM in the cloud.
7. Launch a VM into the cloud that meets the Tableau Server recommendations.
8. Install Tableau Server on the VM in the cloud. For more information, see:
 - [Install Tableau Server on Amazon Web Services](#)
 - [Install Tableau Server on the Google Cloud Platform](#)
 - [Install Tableau Server on Microsoft Azure](#)
 - [Install Tableau Server in the Alibaba Cloud](#)
9. After installation is complete, copy any SSL files to Tableau Server on the VM in the cloud, and restore the backup on your new server.
10. Configure Tableau Server on the VM in the cloud and install all SSH and port related stuff.

Note: If you change the IP address/port of the database, you might need to update all connection information.

11. Copy your backup file `.tsbak` to the folder location specified by the `base-filepath.backuprestore` variable. By default this is: `C:\ProgramData\Tableau\Tableau Server\data\tabsvc\files\backups\`.

Note: You can change the location for the backup file. For more information, see [tsm File Paths](#).

12. Next, stop Tableau Server. At a command prompt, type:

```
tsm stop
```

13. Restore your in-production data without configuration information to your new Tableau Server installation. At a command prompt, type:

```
tsm maintenance restore -f <filename>
```

where `<filename>` is the name of the `.tsbak` file you copied in step 11.

For more information about restoring Tableau Server data, see [Restore from a Backup](#).

14. Start the server. At a command prompt, type:

```
tsm start
```

15. **Distributed installations only:** Install Tableau Server on the new VMs you want to add to your new Tableau Server cluster in the cloud. For more information, see:

- [Install and Configure Additional Nodes](#)
- [Self-Deploy Tableau Server on AWS in a Distributed Environment](#)
- [Self-Deploy Tableau Server on the Google Cloud Platform in a Distributed Environment](#)
- [Self-Deploy Tableau Server on Microsoft Azure in a Distributed Environment](#)
- [Self-Deploy Tableau Server on Alibaba Cloud in a Distributed Environment](#)

16. Test your Tableau Server on your VM in the cloud to ensure that it works as expected. If your Tableau Server is working fine in the cloud, you can deactivate your on-premises Tableau Server product key and use this same product key to activate your Tableau Server on the VM in the cloud.

Note: If you do not have an internet connection, you are prompted to create an off-line activation file to complete the deactivation process. For more information, see [Deactivate Tableau Server Offline](#).

17. The same Tableau Server product key can be activated three times: once for a production environment, once for a test environment, and once for a QA environment. After you have tested your new Tableau Server installation and confirmed that it's ready for production, you must deactivate your earlier production version of Tableau Server, and then you must uninstall it. To deactivate the earlier version, see [tsm licenses deactivate](#).

Note: If you do not have an internet connection, you are prompted to create an off-line activation file to complete the deactivation process. See [Deactivate Tableau Server Offline](#) for steps.

Changing the Identity Store

Infrastructure or business changes may require you to change the identity store on Tableau Server. There are two kinds of identity stores: local and external. When you installed Tableau Server you configured either a local identity store or an external identity store.

When you configure Tableau Server with a local identity store, all user and group information is stored and managed in the Tableau Server repository. In the local identity store scenario, there is no external source for users and groups.

When you configure Tableau Server with an external store, all user and group information is stored and managed by an external directory service. Tableau Server must synchronize with the external identity store so that local copies of the users and groups exist in the Tableau

Server repository, but the external identity store is the authoritative source for all user and group data. Examples of external identity stores are OpenLDAP and Active Directory.

For more information about the Tableau identity store, see [Identity Store](#).

You can change from local store to an external store, or you can change from an external store to a local store. In either case, to change the identity store type, you complete these steps:

1. Uninstall and then reinstall of Tableau Server. The procedure for full uninstall and clean install are at the end of this topic.
2. Restore content and permissions.

In these steps the term "restore" does not refer to using the `TSM maintenance restore` command to restore the backup you are making. You cannot restore a backup (`.tsbak`) created on a Tableau Server instance that uses a different identity store than the target Tableau Server. The backup is a best practice safeguard, in case you need to go back to your original Tableau Server configuration.

Warning

Changing the installation type on Tableau Server can be a complicated and time-consuming process. To avoid data loss or orphaning of content or users, you'll need to plan this process carefully. In all cases, user filters applied to workbooks and data sources will need to be updated manually after the change.

Most importantly, determine how you will transition content and permissions to the new identity store after you reinstall Tableau Server.

Methods for restoring content and permissions

The following list describes two methods for restoring content and permissions after you reinstall Tableau Server. Select the method that best fits with your environmental requirements.

- **Method 1: Use site export and import**—In this method, you start by exporting each site in your existing deployment. Then, you install the new server and configure it for the new identity store type. You then create new users in the default site on the new server. Finally, you import all the original sites. During the import stage, you can map the original identities to the new users that you created in the default site.

Note: When migrating sites between instances of Tableau Server, the target site must be on a version of Tableau Server that is the equal to or later than the version of Tableau Server for the source site. Both the source and target sites must be from supported versions of Tableau Server.

Because this method exports all content and permissions at each site, it is the best method for organizations that require a high fidelity replica of the content and permissions after the identity store change is complete. Some organizations require an identity store change as the result of an authentication change. In these cases, a different user name syntax is often a requirement in the new model. This method, which includes a process of mapping original user names to new names, provides flexibility for such scenarios.

- **Method 2: Fresh installation; users republish content**—In this method, you install a new version of Tableau Server and select the new identity store type during setup. You also create new sites. You then create users and give them access, and they republish their workbooks and data sources. Unlike the other method, in this one, you do not reuse any of your existing Tableau Server infrastructure.

This method is most appropriate for smaller deployments with fairly autonomous and data savvy users. From an administrative perspective, this method is the simplest, since you're not actively porting over content. However, because you rely entirely on users to republish content, this method may not be successful for large organizations or for those where centralized oversight of content is required.

User filters

User filters are domain-specific. Therefore, when the domain of Tableau Server changes or authentication type changes, filters no longer function as expected. Although the user filters are generated by Tableau Server, after they are set by the user, the filters are stored in the workbooks and data sources. Neither of these methods for changing the identity store modifies the contents of the workbooks or data sources.

As you plan the identity store change, you must also include a final task to correct user filtering in all workbooks and data sources with Tableau Desktop.

User names and the Tableau Identity store

If you are using Method 1, it's helpful to understand how Tableau Server stores user names in the Tableau identity store. Tableau stores all user identities in the repository, which coordinates content permissions and site membership with various services in Tableau Server. Generally, an identity store configured for Active Directory store user names in the format, `domain\username`. Some organizations use a UPN (`jsmith@domain.lan`).

On the other hand, organizations that configure Tableau Server with local identity store usually create standard, truncated user names, such as `jsmith`.

In all cases, these user names are literal strings that must be unique in the Tableau identity store. If you are changing from one identity store type to another, then your target authentication, SSO, or user provisioning solution may require a specific user name format.

Therefore, to maintain all permissions, content, and user viability, one of the following must be true after you change the identity store type:

- The new user names must match the original user names, or
- The original user names must be updated to match a new format.

If an authentication change is driving the identity store change, then the target authentication scheme will likely impose a user name syntax that is different than your original user names. Method 1 includes a process where you can map original user names to new user names.

It's possible that the original user name format will work with the new authentication type. For example, if you used UPN names in a local identity store deployment, you might be able to use the same user names in an Active Directory deployment. You could also use the `domain\username` format for local identity store, as long as users continue to use that format to sign in to Tableau Server.

If you are changing from local identity store to an external Active Directory store, review the topic, [User Management in Deployments with External Identity Stores](#), as part of your planning process.

Method 1: Use site export and import

You must use the same version of Tableau Server for the export and import operations.

1. Export all sites on your server. See [Export or Import a Site](#).
2. Back up, remove, and then reinstall .
3. Create new users on Tableau Server. You should have a new user that corresponds to each user on the original server.
4. Import the sites that you exported in Step 1. See [Export or Import a Site](#). During import, you will be prompted to map the new users to the original users.

Method 2: Fresh installation—users republish content

Even if you do not plan to port content as part of your identity store change, we recommend that you back up the server.

1. Back up, remove, and then reinstall .
2. Create users, sites, and groups.
3. Inform your users of the new Tableau Server, provide them with credentials, and allow them to republish their content.

Back up, remove, and then reinstall

Both methods include the following steps:

1. Back up Tableau Server
2. Remove Tableau Server.
3. Reinstall Tableau Server with the new identity store type.

Step 1: Back up Tableau Server

As a best practice, you should back up the server before proceeding.

Follow the procedure, Create a backup using the TSM command line interface (CLI). Run the `backup` command with the `-d` option. The `-d` option adds the datestamp.

When you are finished, copy the backup file (`.tsbak`) to a safe location that is not a part of your Tableau Server installation.

Step 2: Remove Tableau Server

You must completely remove Tableau Server from the computer. See [Remove Tableau Server from Your Computer](#).

Step 3: Reinstall Tableau Server with new authentication type

1. Go to the Tableau Customer Portal, sign in with your Tableau user name and password, and then download Tableau Server.
2. Install Tableau Server. See [Install and Configure Tableau Server](#) more information. During installation, you will select the new identity store type. See [Configure Initial Node Settings](#).

Manage Individual Sites

In addition to planning your sites in Tableau, you can manage users and groups, manage projects and control content access, manage your site data, and interact with views on the web.

What is a site	469
Planning a Site	472
Site Settings Reference	475
Manage Users and Groups	490
Dashboard-based Custom Portals	552
Manage Content Access	556

What is a site

You might be used to using the term *site* to mean “a collection of connected computers,” or perhaps as the short form of “website.” In Tableau-speak, we use site to mean a collection of users, groups, and content (workbooks, data sources) that’s walled off from any other groups and content on the same instance of Tableau Server. Another way to say this is that Tableau Server supports multi-tenancy by allowing server administrators to create sites on the server for multiple sets of users and content.

All server content is published, accessed, and managed on a per-site basis. Each site has its own URL and its own set of users (although each server user can be added to multiple sites). Each site’s content (projects, workbooks, and data sources) is completely segregated from content on other sites.

If you are a server administrator on your Tableau Server deployment, you can learn more about sites, when to use them (vs. projects), and more in [Sites Overview](#), in the **Manage Server** section.

Note: This article pertains to configuring sites on Tableau Server deployments. For Tableau Cloud, see [Site Administrator Role and Tasks](#).

Site administrator tasks

Where the Server Administrator site role gives a user unrestricted access to the entire Tableau Server deployment, the Site Administrator site roles give a user unrestricted or minimally restricted access at the site level. The differences between Site Administrator Creator and Site Administrator Explorer are in the level of data connection and publishing access. Both site roles allow administering the site itself and managing site users. For more information, see [Set Users' Site Roles](#).

Although a server administrator can work at both the server and site levels, we make a distinction between the two levels of task. The site administrator is typically in charge of creating and maintaining the framework that enables Tableau users in the organization to publish, share, manage, and connect to data sources and workbooks. In this vein, site administrator tasks include any of the following (and both site roles allow this level of access):

- Creating project hierarchies to organize the site's data sources and workbooks.

This can include delegating project-level management to project leaders.

- Creating groups and assigning permissions that allow users to access only the content they need.
- Adding and removing users, assigning their site roles.

This is allowed by default on a site; however, a server administrator can restrict this access to the server level only.

- Managing the site's extract and subscription schedules.
- Monitoring site activity.

For more information about the distinction between server administrator and site administrator, see Administrator-level access to sites, in the **Manage Server** section.

Steps for setting up your site

The table below shows a loose sequence of steps for setting up a site, along with links to topics where you can get more information. You can complete the steps in any order that makes sense for you.

However, before you perform the steps to configure the site, we recommend spending some time with the articles in this section, learning about site authentication, site roles, projects, and permissions. Ideally you would document a plan for your projects, groups, and overall permissions strategy. Then set up a few projects and add a preliminary set of users, to test the plan and resolve issues before you add the remaining users. You can change many site settings after your users are working with the site, but try to go in with the intention of minimizing post-production changes.

Plan	To supplement the recommendations above this table, get an overview of how the site components work together in Planning a Site.
Configure access	<p>Work with the server administrator to determine how users sign in to the site, and configure the site appropriately.</p> <p>For example, if the server is configured for single sign-on using SAML, you might configure SAML authentication at the site level as well.</p>
Create projects and the permissions structure	Projects help you organize content, delegate project-level content management, and manage permissions effectively. To get started, see Use Projects to Manage Content Access.

Add users	Determine the users who can sign in to the site. See Add Users to a Site .
Get your data to Tableau Server	<p>After you create your projects and permissions structure, designate approved users for publishing and managing vetted data sources to the appropriate projects on the site.</p> <p>In some organizations, people serve in multiple Tableau roles. Site administrators commonly also are data stewards. By that, we mean they create, publish, and manage the Tableau data connections. If this is you, make sure you are assigned the Site Administrator Creator site role.</p> <p>After content is published to the site, you can maintain connection information (credentials, access tokens) and refresh schedules. For more information, see Refresh Data on a Schedule.</p>
Analyze site usage and performance	Monitor usage, performance, and other metrics. See Administrative Views .

Planning a Site

Before you add users and content to a site, we recommend that you plan the following aspects of the site.

- [Projects](#)
- [Users and groups](#)

- [Site roles and permissions](#)
- [Extract refresh schedules](#)

The subsequent sections go over these site components, assuming that you are familiar with

Note: This article and section apply only to self-managed Tableau Server deployments on-premises or in the cloud. If you use Tableau Cloud, see [Manage Content Access](#).

Projects

You can create projects on a site, which act as containers in which you can organize related content assets (such as data sources and workbooks). For example, you might set up a project to contain all of the certified data sources and workbooks your organization uses for mission-critical decisions. Or you might set up projects by department.

Projects are also useful for managing permissions. Once you know how your users need to access content, it's usually easier to create projects based on those the type of content, and maintain permissions at the project level.

Every site has a default project named **Default**. When you create projects, the new projects get their initial set of permissions from the default project. In effect, the default project is a template for new projects. As we explain in related articles, for most environments, we recommend that you use the Default project only as a permissions template, and not as a container for published content.

For more information, see [Use Projects to Manage Content Access](#).

Users and groups

Any user who will publish content or access published content on a site must be able to sign in to the site. If the user already has an account on the server, you'll need to add that user to the appropriate site. You can add a user to more than one site as well. If the user doesn't already

exist, you need to create a user account. Either way, make a list of the users who will need to be able to sign in to each site.

Note: The server license might restrict how many users you can have, or what level of access they can have. Check with the server administrator to make sure that you'll be able to have an account for all your users.

In general, we recommend that you create groups on the server and then add users to the groups. This helps to make permissions much easier to manage. You can assign permissions on groups, to give those permissions to all users in the group. (See the next section.)

A typical strategy is to create groups for users who use content in similar ways. For example, you might create a group named SalesWBPublishers for all the users in the Sales department who publish workbooks, and a separate group named SalesDSPublishers for people in Sales who publish data sources. Each of these sets of users needs its own set of capabilities, so it makes sense to have a group for each for these needs.

Site roles and permissions

Each user has a *site role* that determines the maximum permissions that they can have on the site. As part of your site planning, you need to decide each user's site role. A user with a site role that's too restrictive might not be able to do the work they need. By the same token, a security best practice is to limit users' capabilities to only those that they need to do their work. This is referred to as following the principle of *least privilege*.

You or a site administrator you delegate this task to must also determine the permissions a user needs to work with content. Each content asset (workbook, data source, project) supports a set of *capabilities*. For example, you can **View** or **Add Comments** to a workbook. Before a user can perform tasks on a workbook, their permissions must allow those capabilities. A recommended practice is to sketch out a mapping of permissions to users outside of Tableau before you try to set this up on the server.

Permissions determine what a user can do *within the context of the site role*. A user whose site role is **Viewer** can never publish to the site, regardless of the permissions you grant them. A user whose site role is **Creator** can publish a workbook to the site, but only if that user has permission to save and view workbooks.

Extract refresh schedules

If users publish data sources or workbooks that include extracts, you usually want to make sure that the extracts are refreshed, so that they contain the latest data. Users can manually refresh an extract, but this isn't always a good idea if the extract is large, and the refresh takes a long time. Instead, you can set up schedules for when an extract should be refreshed. Another planning task for a site administrator, therefore, is to think about when extracts should be refreshed and to work out schedules.

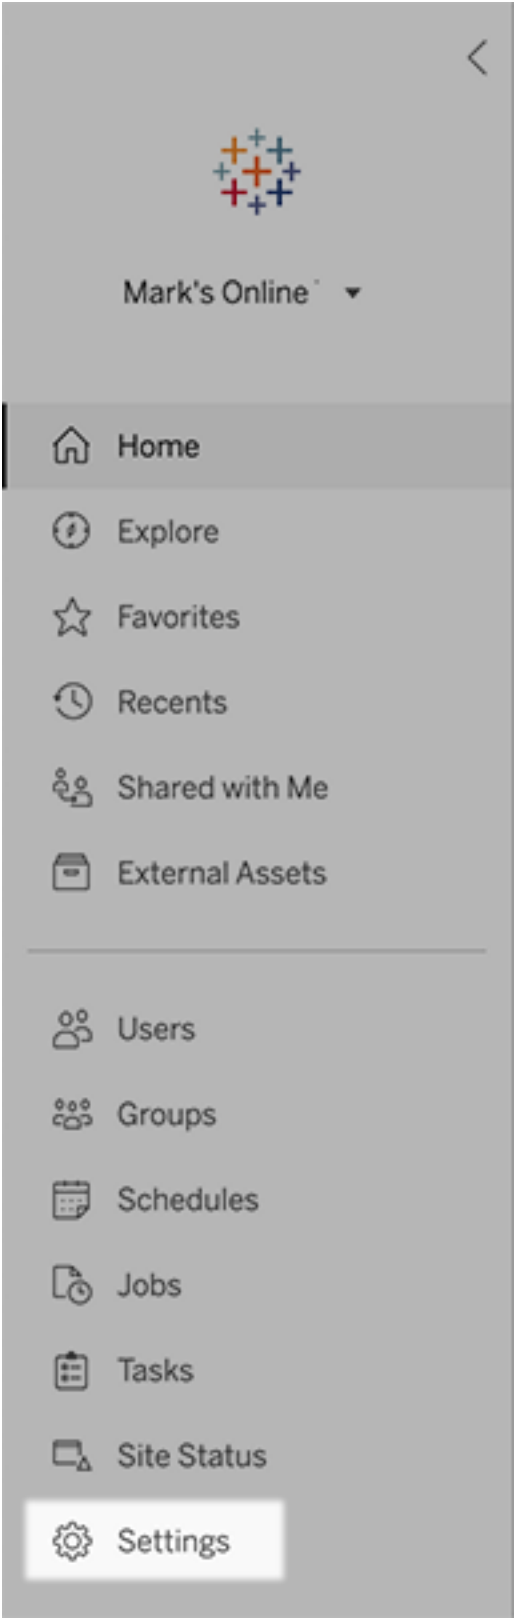

Site Settings Reference

As a Tableau administrator, you can customize a site for your organization using the settings below. The settings available to you depend on your site configuration and whether you use Tableau Cloud or Tableau Server. To view and edit site settings, you must be a Site Administrator on Tableau Cloud or Server Administrator on Tableau Server.

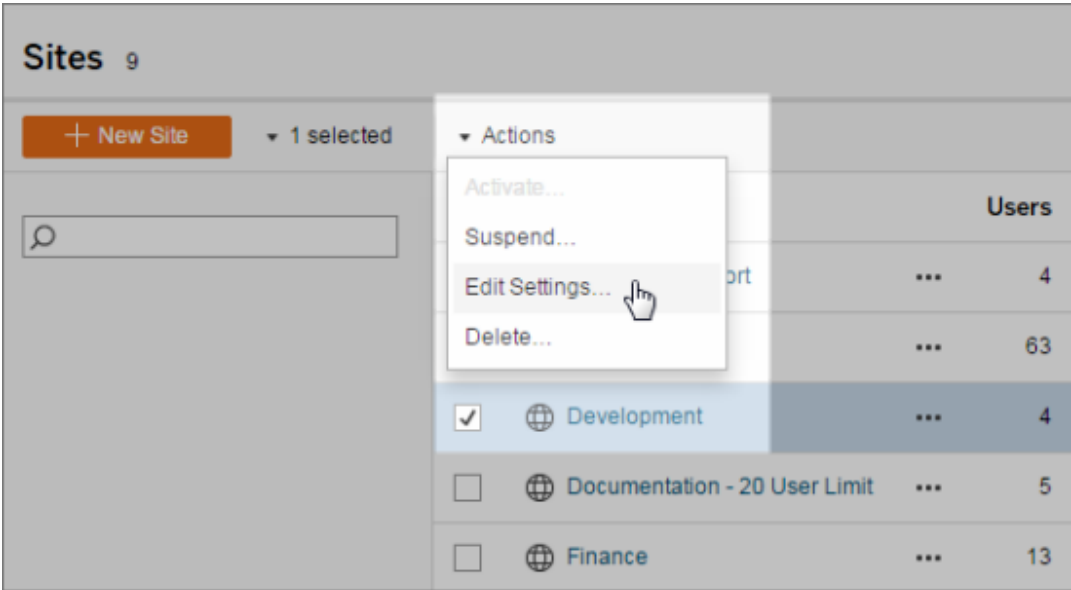

Note: To find a specific setting below, press Ctrl+F (Windows) or Command+F (macOS). Tableau Cloud and Tableau Server present these settings in a different order.

Accessing site settings

- (Tableau Cloud) From the Home page, expand the side pane, and click **Settings** at bottom.

- (Tableau Server) If you're editing an existing site, select it on the Sites page, and then select **Edit Settings**. Or, in a single-site deployment, click **Settings** at the bottom of the side pane.

General tab

Setting	Description
Site Name and ID (Tableau Server Administrators only)	<p>Specifies the site name seen in the user interface and the ID seen in the site URL. (If you are editing the Default site, you cannot change the ID.)</p> <p>You can't change the “#/site” portion of the URL (for example, http://localhost/#/site/sales). In multi-site server environments, these segments appear in the URL for sites other than the Default site.</p>
Storage (Tableau Server Administrators only)	<p>Select either Server Limit or GB, and for the latter enter the number of gigabytes you want as a limit for storage space for published workbooks, extracts, and other data sources.</p> <p>If you set a server limit and the site exceeds it, publishers will be pre-</p>

vented from uploading new content until the site is under the limit again. Server administrators can track where the site is relative to its limit using the Max Storage and Storage Used columns on the Sites page.

Revision History
(Tableau Server Administrators only) Specifies the number of previous versions of workbooks, flows, and data sources that are stored on the server.

Tableau Prep Conductor Controls whether users with appropriate permissions can schedule and monitor flows. Tableau Prep Conductor is part of Data Management. For more information, see [Tableau Prep Conductor](#).

Web Authoring Controls whether browser-based authoring is enabled for the site. When web authoring for workbooks is disabled, users can't create or edit published workbooks from the server web environment but instead must use Tableau Desktop to republish the workbook. When web authoring for flows is disabled, users can't create or edit published flows from the server web environment but instead must use Tableau Prep Builder to re-publish the flow.

For more information, see [Set a Site's Web Authoring Access and Functions](#) in Tableau Cloud Help.

Managing Users
(Tableau Server Administrators only) Determines whether only server administrators can add and remove users and change their site roles, or whether site administrators can too.

If you allow site administrators to manage users, specify how many users they can add to the site by selecting one of the following:

- **Server Limit** adds the number of available server seat licenses. For a server with core-based licensing, there is no limit.
- **Site Limit** lets site administrators add users up to a limit you specify.
- **Site Role Limit** lets site administrators add users of each site

role up to the license limit you specify for the site.

For more information, see [View Server Licenses](#).

Guest Access
(Tableau Server
Administrators only)

Lets people who lack a Tableau Server account see views that have guest access permissions.

Note: If you use Tableau Server, your administrator can disable Guest Access.

Tableau Catalog

Turns off Catalog capabilities when Tableau Server or a Tableau Cloud site is licensed with Data Management. For more information, see [Disable Catalog](#).

Workbook Performance after a
Scheduled Refresh
(Tableau Server
Administrators only)

Pre-computes recently viewed workbooks with scheduled refreshes to open them faster. For more information, see [Configure Workbook Performance after a Scheduled Refresh](#).

Workbook Performance Metrics
(Tableau Server
Administrators only)

Lets site users collect metrics on how workbooks perform, such as how quickly they load To initiate recording, users must add a parameter to the workbook's URL. For more information, see [Create a Performance Recording](#).

Managed Keychain
Clean Up (Tableau
Server Administrators only)

Lets site administrators manage saved credential keychains for OAuth connections on the site. For more information, see [OAuth Connections](#).

Automatically Suspend Extract Refresh
Tasks

To save resources, Tableau can automatically suspend extract refresh tasks for inactive workbooks. This feature applies only to refresh schedules that run weekly or more often. For more information, see [Automatically Suspend Extract Refreshes for Inactive Workbooks](#) in Tableau Cloud Help.

<p>Linked Tasks</p> <p>(Tableau Server and Site Administrators only)</p>	<p>Lets Server administrators enable users to schedule flow tasks to run one after the other. They can also enable users to trigger the scheduled flow tasks to run using Run Now.</p> <p>This setting can be applied at the server level to include all sites on Tableau Server. The setting can be disabled at the site level to include only specific sites.</p> <p>If the setting is turned off after linked tasks are scheduled, any tasks that are running will complete and the scheduled linked tasks are hidden and no longer show on the Scheduled Tasks tab.</p> <p>For more information, see Schedule Linked Tasks.</p>
<p>Email Settings</p> <p>(Tableau Server Administrators only)</p>	<p>Specifies the From address and message footer seen in automatic emails for alerts and subscriptions.</p>
<p>Site Invite Notification</p> <p>(Tableau Cloud only)</p>	<p>For sites with single-sign-on authentication, sends an invite email when new users are added to the site.</p>
<p>Site Logo</p>	<p>Specifies the image that appears with the site name.</p>
<p>Start Page</p>	<p>Controls which site page appears when users sign in. By default, the Home page appears, but you can instead open All Projects, All Workbooks, or other pages. For more information, see Set the Default Start Page in Tableau Cloud Help.</p> <div data-bbox="570 1459 1328 1543" data-label="Text"> <p>Note: If you use Tableau Server, your administrator can override this site setting.</p> </div>
<p>User Visibility</p>	<p>Controls what user and group names are visible to other users. For more information, see Manage User Visibility in Tableau Cloud Help.</p>

Availability of Ask Data	Controls whether Ask Data lenses are enabled or disabled for data sources. Ask Data lets users query data using conversational language and automatically see visualizations. For more information, see Automatically Build Views with Ask Data in Tableau user Help.
Availability of Explain Data	Controls whether site users with the appropriate permissions can run Explain Data and authors can access Explain Data Settings. For more information, see Control Access to Explain Data . To learn more about Explain Data, see Discover Insights Faster with Explain Data .
Automatic Access to Metadata about Databases and Tables	Automatically grants users certain capabilities to external assets using derived permissions. For more information, see Turn off derived permissions in Tableau Cloud Help.
Sensitive Lineage Data	Specifies whether sensitive lineage data should be obfuscated or filtered when users don't have the appropriate permissions to related metadata. For more information, see Sensitive lineage data .
Cross-Database Joins	Determines where the join process happens when joining data from multiple sources. For more information, see Combine Tables from Different Databases in Tableau user Help.
Extract Encryption at Rest (Tableau Server Administrators only)	Lets you encrypt .hyper extracts while they are stored on Tableau Server. Server administrators can enforce encryption of all extracts on their site or allow users to encrypt all extracts associated with particular published workbooks or data sources. For more information, see Extract Encryption at Rest .
Tableau Support Access (Tableau Cloud only)	Allows Tableau Support technicians access to the site to help troubleshoot support cases. By default, this feature is disabled. For more information, see Enable Support Access .
Sharing	Allows users to share items directly with other users. When an item is shared, the recipients get a notification and the item is added to their Shared with Me page. If this is not enabled, users can only

copy a link to share. For more information, see [Share Web Content](#) in Tableau user Help.

Comments Controls whether users can add remarks in a Comments side pane for each view and @mention other Tableau users to notify them via email. For more information, see [Comment on Views](#) in Tableau user Help.

Data-Driven Alerts Lets users automatically receive emails when data reaches key thresholds. For more information, see [Send Data-Driven Alerts](#) in Tableau user Help.

Subscriptions Lets site users subscribe to views and receive regular emails of them. On Tableau Server, these options are available only if you first [configure subscription settings](#).

Data Quality Warnings in Subscriptions Controls whether subscriptions include relevant upstream high visibility data quality warnings and sensitivity labels in the email. On Tableau Server, these options are available only if you first [turn on and configure subscriptions](#). For more information on data quality warnings, see [Set a Data Quality Warning](#). For more information on sensitivity labels, see [Sensitivity Labels](#).

Note: Data quality warnings and sensitivity labels are a feature of Tableau Catalog, which is part of Data Management.

Tagging Specifies the number of tags that users can add to items. The default limit is 50 tags, and the maximum is 200. For more information, see [Use Tags](#).

Recommendations for Views Controls whether recommendations show on the site and whether the names of users who have looked at recommended items show on recommendation tooltips.

Note: If you use Tableau Server, your administrator can disable Recommendations.

Request Access	Lets users send access requests to content or project owners. For more information, see Let Site Users Request Access to Content in Tableau Cloud Help.
Metrics Content Type	Controls whether metrics are available on the site. When you turn metrics on, users can create metrics from views and metrics appear as a content type. When turned off, metrics won't appear on the site or continue to sync. If you turn on metrics again, pre-existing metrics will reappear and resume refreshing. For more information, see "Set Up for Metrics" in Tableau Cloud Help or Tableau Server Help .

Important changes coming for Ask Data and Metrics

Tableau's Ask Data and Metrics features will be retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau GPT and Tableau Pulse are reimagining the data experience](#).

In October 2023, Tableau retired the ability to embed metrics in Tableau Cloud and Tableau Server version 2023.3, in advance of the retirement of the Metrics feature

Web Page Objects and Web Images	Controls whether these Web Page and Image objects can display target URLs. For more information, see Security for Web Page objects in Tableau user Help.
Personal Space	Allows Creator and Explorer site users to create and save content to a private Personal Space. When Personal Space is turned on,

you can set user storage limits. For more information, see [Create and Edit Private Content in Personal Space](#).

Collections	Controls whether collections are available on the site. When you turn on collections, users can create collections to organize content and browse collections made available by other users. For more information, see Organize Items in a Collection .
Site Time Zone for Extracts	The default time zone for extract-based data sources in a site is Coordinated Universal Time (UTC). Site administrators can set a different time zone. For more information, see Set the Site Time Zone for Extracts in Tableau Server Help or Set the Site Time Zone for Extracts in Tableau Cloud Help.
Extract Quota Limit Notifications	Sends email alerts to all site administrators when extract refresh jobs are canceled because of extract job capacity issues.
Flow Parameters	Enables users to schedule and run flows that include parameters.
(Tableau Server and Site Administrators only)	<p>Administrators can also enable flow parameters to accept any value. If this option is enabled, any flow user can enter any value in a parameter, potentially exposing data that the user should not have access to.</p> <p>Parameters can be entered in an input step for file name and path, table name, or when using custom SQL queries, in an output step for file name and path and table name, and in any step type for filters or calculated values.</p> <p>Flow parameter settings can be applied at the server level to include all sites on Tableau Server. The settings can be disabled at the site level to include only specific sites.</p> <p>For more information about using parameters, see Create and Use Parameters in Flows in the Tableau Prep help.</p>

Run Now Controls who can run jobs manually using the Run Now option from the web, Rest API, and Tabcmd. By default, this option is selected to allow users to run jobs manually. Clear the check box if only administrators should be allowed to run jobs manually.

Note: If you use Tableau Server, your administrator can disable this site setting.

Manage Notifications Controls how site users can receive notifications for events such as extract jobs, flow runs, when another user shares content with them or mentions them in a comment. Notifications can be seen in their Tableau site via the notification center, sent by email, or sent to a Slack workspace. When a notification is enabled, users can configure their notification preferences on their Account Settings page.

Note: If you use Tableau Server, your server administrator can disable this site setting.

Notification Email Settings (Tableau Cloud only) Controls whether the email notifications sent to users for data-driven alerts and subscriptions include links. These links direct users to your Tableau site to see the content and manage the alert or subscription. Added for Tableau Cloud in 2023.2.

Flow Subscriptions Controls whether flow owners can schedule and send emails with flow output data to themselves and others. When you allow flow subscriptions, you can control whether flow output data is included in the subscription email and whether flow output files are attached to the email. For more information, see [Notify Users of Successful Flow Runs](#)

OAuth Clients Registry For a subset of connectors, you can register a custom OAuth client for the site to override an OAuth client that has been configured for the server. By registering a custom OAuth client, you enable new

and existing connections to use the site-level OAuth client instead of the server-wide OAuth client. For more information, see [Configure Custom OAuth](#).

View Acceleration	Controls whether Creator and Explorer site users can accelerate the views in their workbooks for faster loading times. When you allow view acceleration, you can set a maximum number of views to be accelerated, and you can choose to automatically suspend acceleration for views that repeatedly fail the acceleration task. For more information, see View Acceleration.
-------------------	---

Authentication tab (Tableau Cloud)

Setting	Description
Authentication Types	Specifies how users can sign in to the site, and how they access it after signing in the first time. Authentication verifies a user's identity. For more information, see Authentication .
Default Authentication Type for Embedded Views	Specifies how users can sign in to embedded views. By default, Tableau authentication is selected.
Control User Access in Authentication Workflows	Enables user attribute functions used in embedded content to accept the passing of user attributes from a JSON Web Token (JWT). The user attributes are passed to Tableau to customize and control the data that can be shown to a user at runtime. For more information, see Embedding API v3 Help .
Automatic Provisioning and Group Synchronization (SCIM)	Allows you to manage users on the site through a third-party identity provider (IdP). When enabled, the Base URL and Secret boxes are populated with values to use in the IdP SCIM configuration. For more information, see Automate User Provisioning and Group Synchronization through an External Identity Provider .
Connected Clients	Allows Tableau clients such as Tableau Mobile, Tableau Bridge, and others to stay authenticated to the server after a user provides sign-in

credentials the first time. When turned off, users are required to sign in explicitly each time they visit Tableau Cloud. For more information, see [Access Sites from Connected Clients](#).

Bridge tab (Tableau Cloud)

Setting	Description
Client Not Running Notifications	Sends email alerts to data source owners when a client appears to be disconnected from the site.
Pooling	Distributes live queries and refresh jobs across all clients in Bridge pools. For more information, see Configure and Manage the Bridge Client Pool in the Tableau Cloud Help.
Private Network Allowlist	Add and manage domains that enable dedicated Bridge pool access to private network data on behalf of Tableau Cloud.

Extensions tab

Setting	Description
Dashboard Extensions	Manage and control dashboard extensions. Dashboard extensions are web applications that run in custom dashboard zones and can interact with the rest of the dashboard. For more information, see "Manage Dashboard Extensions" in Tableau Cloud Help or Tableau Server Help .
Analytics Extensions	Enables a set of functions that your users can use to pass expressions to analytics extensions for integration with R and Python. For more information, see "Configure Connection with Analytics Extensions" in Tableau Cloud Help or Tableau Server Help .
Tableau Prep Extension	When authoring flows on the web, enables users to apply Einstein Discovery-powered models to their flows to bulk score predictions for their data.

For more information, see [Configure Einstein Discovery Integration](#) in the Tableau Server help.

Integrations tab

Setting

Description

Slack Connectivity

Displays connections between a Slack workspace and the Tableau site. When connected, Tableau site users can see their Tableau notifications in the connected Slack workspace.

Note: In Tableau Server, a Slack administrator must create a private Slack app and install it to a Slack workspace before a Tableau server administrator can add an OAuth Client and connect to Slack.

In Tableau Server, you can add OAuth client information for a private Slack application, then select Connect to Slack to finalize the connection. For more information, see [Integrate Tableau with a Slack Workspace](#).

Analytics Extensions

Enables a set of functions that your users can use to pass expressions to analytics extensions for integration with R and Python. For more information, see "Configure Connection with Analytics Extensions" in [Tableau Cloud Help](#) or [Tableau Server Help](#).

Publish to Salesforce

Allows site users to publish views to a Salesforce app.

(Beta on Tableau Cloud and Tableau Server)

When a view is published to Salesforce, anyone with access to the selected app can see that the content exists. However, only those signed in with existing

Tableau permissions can see the view. For more information, see [Publish Views to Salesforce \(Beta\)](#).

Connected Apps tab

Setting

Connected Apps

Description

Create and manage Tableau connected apps, or explicit direct trust relationships or OAuth 2.0 trust between your Tableau Cloud site and custom applications and programmatically authorize access to the Tableau REST API on users' behalf using JSON web tokens (JWTs). For more information, see [Use Tableau Connected Apps for Application Integration](#) in the Tableau Cloud Help.

Mobile tab

Setting

App Lock

Description

Requires a biometric method or device passcode for users to open this site on Tableau Mobile. For more information, see [Enable App Lock for Added Security](#) in the Tableau Mobile Deployment Guide.

Offline Previews

Controls whether offline previews are generated for display when users access the site on Tableau Mobile. For more information, see [Manage Tableau Mobile Data on Devices](#) in the Tableau Mobile Deployment Guide.

Mobile Security Policies

Some security policies are enabled automatically and cannot be disabled. Mobile security policies are not available for MAM versions of Tableau Mobile.

Jailbreak Detection	Controls whether a Tableau Mobile app user with a device that has been "jailbroken" or "rooted" is allowed to access content on Tableau, and what level of response occurs when a jailbroken or rooted device is detected. For more information, see Tableau Mobile App Security Settings.
Malware Detection (Android only)	Controls whether malware detection is enabled for mobile devices, and what level of response occurs when malware is detected. For more information, see Tableau Mobile App Security Settings.
Maximum Days Offline Without Policy Refresh	Controls whether there is a maximum number of days a mobile device can be offline and still use the app. For more information, see Tableau Mobile App Security Settings.
Prevent Debugging	Controls whether debuggers are prevented on mobile devices. For more information, see Tableau Mobile App Security Settings.
Screen Sharing and Screenshots (Android only)	Controls whether a Tableau Mobile user is able to take screenshots or use screen sharing while in the app. For more information, see Tableau Mobile App Security Settings.

Manage Users and Groups

You can add users to your Tableau sites and set their site roles, which determines each user's level of access. In addition, you can create groups of users, and enable guest access to your sites.

Add Users to a Site

Everyone who needs to access Tableau Server—whether to browse, publish, edit content or administer the site—must be added as a user. Administrators have the following options for adding users:

- Add a local user account or a user account from Active Directory, described later in this article.

You can also add users by importing an Active Directory group. See [Create Groups via Active Directory](#).

- Import Users via a CSV file that you create using the [CSV Import File Guidelines](#).

Site administrator access to user management

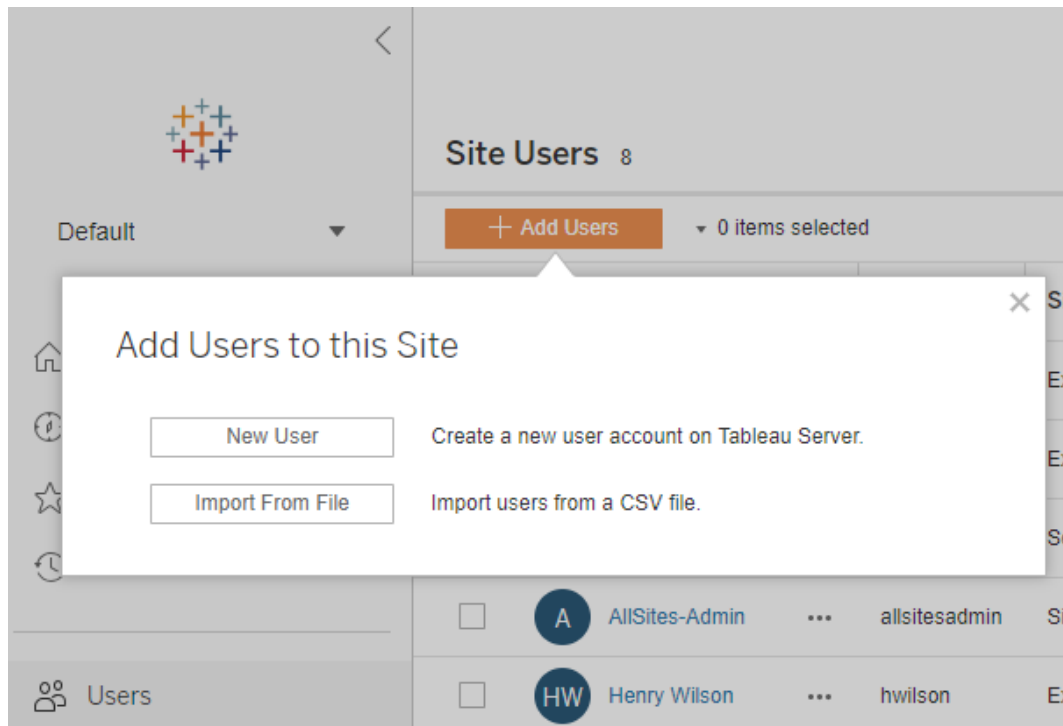

By default site administrators can add and remove users on a site. On the site's Settings page, server administrators can revoke that capability, so that only server administrators can manage the site's users.

A site administrator can edit an existing local user account only if the administrator has access to all of the sites the user is a member of. For example, if User1 is a member of sites A and B, an administrator of only site B cannot edit User1's full name or reset the password.

Note: When using local authentication, if a site administrator is able to add and remove users, they will be able to tell if a username is configured as a user on any site of Tableau Server

Add local users to a site

1. Sign in to Tableau Server as an administrator, and if applicable select the site.
2. Select **Users**. On the Users page, click **Add Users**, and then click **New User**.

3. Enter a user name. With local authentication, using an email address for the user name is the best way to avoid user name collisions (for example, *lrodriguez@example.com* instead of *lrodriguez*).

New User

Username:	<input type="text" value="lrodriguez@example.com"/>
	Username available
Display name:	<input type="text" value="Laura Rodriguez"/>
Password:	<input type="password" value="....."/>
Confirm password:	<input type="password" value="....."/>
Email (optional):	<input type="text"/>
Site role:	<div><input type="text" value="Creator"/>▼</div> <div></div>

User names are not case sensitive. Characters not allowed in user names include the semi-colon (;) and colon (,).

Also enter information in the following fields:

- **Display Name**—Type a display name for the user (e.g., *Laura Rodriguez*).
- **Password**—Type a password for the user.
- **Confirm password**—Retype the password.
- **Email**—This is optional and can be added at a later time in the user profile settings.

4. Select a site role.

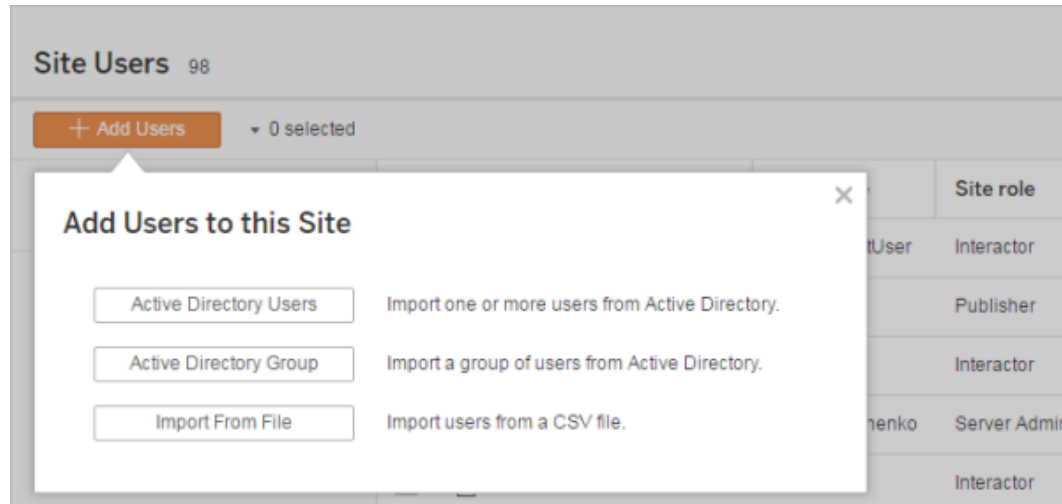

For site role definitions, see [Set Users' Site Roles](#).

5. Click **Add User**.

Add Active Directory users to a site

Before adding users to a site, be sure to review User Management in Deployments with External Identity Stores to understand how multiple domains, domain naming, NetBIOS, and Active Directory user name format influence Tableau user management.

1. In a site, click **Users**, and then click **Add Users**, and then click **Active Directory User**.

2. Enter one or more user names (separated by semicolons).

For example, *tdavis; jjohnson; hwilson*

If you are adding a user that is from the same Active Directory domain that the server is running on, you can type the AD user name without the domain. The server's domain will be assumed.

Note: Do not enter the user's full name in this field; it can cause errors during the importing process.

3. Select a site role.

For site role definitions, see [Set Users' Site Roles](#).

4. Click **Import Users**.

Remove local users

1. Sign in to Tableau Server as an administrator, select the site, and open the **Users** page.
2. Select the check boxes next to the users' names, and on the **Actions** menu, select **Remove**.

If a user is a member only of the current site, and they do not own any content, the user is removed from the server.

If a user you remove from the current site is a member of other sites on the server, their status remains unchanged on those sites.

Related information

- You can also [Add Users to Tableau Server](#), without site affiliation.
- Upgrading Tableau Server to version 2018.1 or later from a pre-2018.1 version, without activating user-based licenses, affects users who were assigned the **Viewer** site role in the pre-2018.1 server version.

To learn more, see the section “User-based licenses” in the [Licensing Overview](#) and see [Set Users' Site Roles](#).

Set Users' Site Roles

When you add users to a site on Tableau Server, independent of their license type, you must apply a *site role* to them. The site role signifies the maximum level of access a user can have on the site. Along with content permissions, the site role determines who can publish, interact with or only view published content, or who can manage the site's users and administer the site itself.

Looking for Tableau Server on Linux? See [Set Users' Site Roles](#).

How user licenses, site roles, and content permissions work together

The intersection of a user's license type, site role, and content permissions determines the level of access a user has on the Tableau site.

Note: The license level count at the top of the header on the **Server Users** tab may differ from the count under the **Max User Role** filter due to some users having different roles across sites.

1. The license type is associated with the user. The site role you want to assign to the user determines the license type they require.

In a multi-site environment on Tableau Server, a user's license applies to all sites the user is a member of.

2. The site role is also set at the user level. In a multi-site environment, you assign site roles on each site. For example, the same user can have the Site Administrator Creator site role on one site, and Viewer site role on another site.

The site role defines the maximum capabilities the user can have.

3. Whether the site role's maximum capabilities are available to the user depends on the permissions set on the content resources (projects, data sources, workbooks).

For example, let's say that a user has the following access on a site:

- Creator license (due to their access on another site)
- Explorer site role (on this site)
- Save permission capability on a project (on this site)

In this scenario, the license allows connecting to and creating new data sources in the web editing environment or Tableau Desktop, and a permission rule allows them to save in a project. However, their site role prevents them from being able to save, so their effective permissions don't include the save capability. Therefore, the user can't publish content to the site.

Even if a user has a creator license and a creator site role, if they don't have the save capability on at least one project, they can't publish anything to the site.

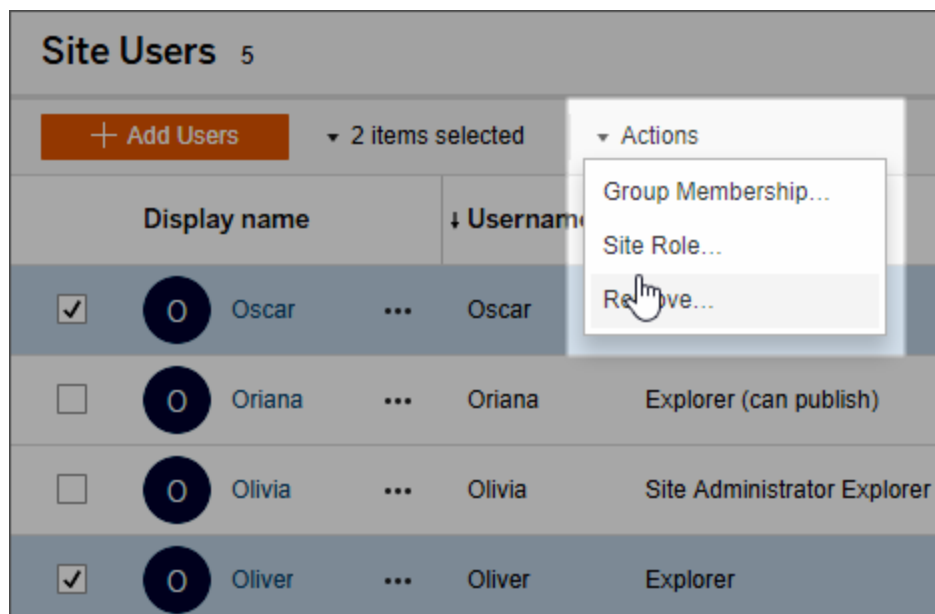

For more information, see [Permissions](#).

Change a user's site role

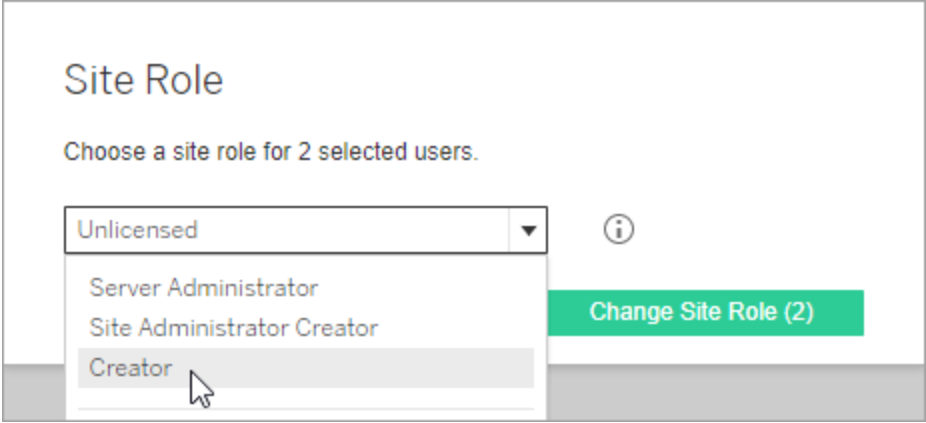

1. Sign in to the site as a server or site administrator, and go to the **Users** area.

If you are a site administrator and don't see the **Users** area, check with your server administrator on whether they have denied user management capabilities to site administrators.

2. Select the users, and then select **Actions > Site Role**.

3. Select the new site role, and then click **Change Site Role**.

You can hover the pointer over the information icon to display a matrix that shows the maximum level of general capabilities each site role allows. For more information, continue to [General capabilities allowed with each site role](#).

General capabilities allowed with each site role

The following table lists the license types as of version 2018.1, the highest level of site role allowed with each, how each site role maps to its pre-2018.1 equivalent; and summarizes the maximum capabilities each site role allows.

What this article covers and where to find what's not covered here

- This information focuses on *site* roles and is more generalized. For a list of common specific tasks available per *license* role, see the matrix on the [For Teams & Organizations](#) tab on the Tableau pricing page.
- This information describes site roles as of version 2018.1. To learn more about how core-based licensing relates to user-based licensing, how licenses transfer, or other specific licensing transition scenarios, start with the following topics:

[Migrate from Core-Based to Role-Based Licensing](#)

Tableau site roles as of version 2018.1

Site role name as of version 2018.1	Previous site role name	Maximum capabilities this site role allows
Site roles that use a Creator license		
—Users with these site roles have access to Tableau clients such as Tableau Prep, Tableau Desktop, Tableau Bridge, and Tableau Mobile.		
Server Administrator	Server Administrator	<p>Available on Tableau Server only; not applicable to Tableau Cloud.</p> <p>This site role always occupies the highest license activated on the server between Creator and Explorer. It allows unrestricted access to the configuration settings for the Tableau Server browser environment, all sites on the server, users and groups, and all content assets, such as flows, projects, data sources (including connection information), and workbooks.</p> <p>Connect to Tableau published data sources or external data, from the browser, Tableau Desktop, or Tableau Prep; create and publish new data sources; author and publish workbooks.</p>
Site Administrator Creator	--	<p>This is the highest level of access for Tableau Cloud.</p> <p>Unrestricted access to content as described above,</p>

Site role name as of version 2018.1	Previous site role name	Maximum capabilities this site role allows
		<p>but at the site level. Connect to Tableau or external data in the browser, Tableau Desktop, or Tableau Prep; create new data sources; build and publish content.</p> <p>On Tableau Server, server administrators can determine whether or not to allow site administrators to manage users and assign site roles and site membership. By default, on Tableau Server, and always on Tableau Cloud, site administrators are allowed these capabilities.</p>
Creator	--	<p>This is similar to the former Publisher site role, but allows new features. This site role offers non-administrators the maximum level of <i>content</i> access.</p> <p>Connect to Tableau or external data in the browser, build and publish flows, data sources and workbooks, have access to Dashboard Starters, and use interaction features on published views. Can also connect to data from Tableau Prep or Tableau Desktop, publish (upload/save) and download flows, workbooks and data sources.</p>
Site roles that use an Explorer license		
—Users with these site roles can access the server from the browser or Tableau Mobile.		
Server Administrator	N/A	<p>Tableau Server only; not applicable to Tableau Cloud.</p> <p>If Explorer is the highest license type activated on the</p>

Site role name as of version 2018.1	Previous site role name	Maximum capabilities this site role allows
		<p>server when a new server administrator user is created, the user's site role is Server Administrator. However, the user won't have the full connecting and publishing capabilities that come only with the Creator license.</p> <p>With the Explorer license a Server Administrator has unrestricted access to the configuration settings for the Tableau Server browser environment, all sites on the server, users and groups, and all content assets, such as projects, flows, data sources (including connection information), and workbooks.</p> <p>However, with the Explorer license, a Server Administrator can't connect to external data from the browser to create a new data source. They can author or publish workbooks and data sources from Tableau Desktop. With regards to publishing, they have the same capabilities that the Explorer (can publish) site role does. They can't publish Tableau Prep flows.</p>
Site Administrator Explorer	Site Administrator	<p>Same access to site and user configuration as Site Administrator Creator, but can't connect to external data or virtual connections from the web editing environment.</p> <p>Can connect to Tableau published data sources to create new workbooks, and edit and save existing workbooks. Can't publish Tableau Prep flows.</p>

Site role name as of version 2018.1	Previous site role name	Maximum capabilities this site role allows
Explorer (can publish)	Publisher	<p>Can author or publish workbooks and data sources from Tableau Desktop. Can also publish workbooks from the web using existing data sources, browse and interact with published views, and use all interaction features.</p> <p>In the web editing environment, can edit and save existing workbooks. Can't save new standalone data sources from data connections embedded in workbooks, and can't connect to external data or virtual connections, or create new data sources.</p>
Explorer	Interactor	<p>Can browse and interact with published views. Can subscribe to content, create data driven alerts, connect to Tableau published data sources and open workbooks in the web authoring environment for ad-hoc queries, but they can't save their work. Can't connect to a virtual connection. Can't publish Tableau Prep flows.</p>
Read Only	Viewer	<p>This site role is available only in version 2018.1, for transitioning users to the user-based Viewer (or other) license and site role. Any users in the Read Only site role prior to upgrading to version 2018.2 or later are reassigned to the Viewer site role.</p> <p>In 2018.1 versions, Read Only users can see and subscribe to published views others have created. Can't use other interaction features or save custom views.</p>

Site role name as of version 2018.1	Previous site role name	Maximum capabilities this site role allows
Site roles that use a Viewer license		
Viewer	N/A	<p>Can see published views others have created and use most interaction features. Can subscribe to views and download as images or summary data. Can't connect to data, create, edit, or publish content, or set data alerts.</p> <p>For a list of specific capabilities, see the Viewer column in the matrix on the Tableau pricing page.</p> <p>Note: Although the Viewer site role existed in previous versions, the new Viewer site role has additional capabilities.</p>
Other site roles		
Unlicensed	Unlicensed	<p>Unlicensed users can't sign in to Tableau Server or Tableau Cloud. Users are assigned the Unlicensed role in the following circumstances:</p> <ul style="list-style-type: none"> You import users from a CSV file and their license level is set to unlicensed. The number of available licenses is reached at the time you add or import users. You remove a user who owns content on the site. The user will still own the content but not be able to do anything with it. A product key(s) has expired. See Refresh Expiration Date and Attributes for the Product

Site role name as of version 2018.1	Previous site role name	Maximum capabilities this site role allows
		Key.

Who can publish content

The following site roles allow the specified level of publishing access.

- **Server Administrator** (Tableau Server only); **Site Administrator Creator**; and **Creator** allow full connecting and publishing access.

This includes connecting to data and publishing new flows, new workbooks and new data sources from Tableau Desktop and the web editing environment. The site roles also allow editing and saving existing published workbooks, or publishing updates to existing data sources.

- **Explorer (Can Publish)** and **Site Administrator Explorer** have limited publishing capabilities, as described in General capabilities allowed with each site role.
- **Explorer**, **Viewer**, **Read Only**, and **Unlicensed** don't allow publishing.

Site roles and Active Directory import and synchronization

When you import users from an external directory like Active Directory, you can specify the site role. If a user is not yet a member of any site on the server, the user is added to the site with the assigned role. When you synchronize groups from an external directory, the site role is applied through the **Minimum Site Role** setting on the **Groups - Details** page.

Note: In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

If a user already exists in a Tableau Server site, the site role assigned during the import or sync process will be applied if it gives the user more access in a site. Importing or synchronizing AD users and groups can promote a user's site role, but does not demote a user's site role.

If a user already has the ability to publish, that ability is maintained.

The matrix below shows the rules applied for site roles on import.

Note: The **Import Site Role** row abbreviated headers indicate the site role specified for import. The **Current Site Role** column headers represent the current user site role. The table values represent the abbreviated resulting site role.

- Site Administrator: SA
- Site Administrator Creator: SC
- Site Administrator Explorer: SE
- Creator: C
- Explorer: E
- Explorer (Can Publish): EP
- Viewer: V
- Unlicensed: U

	Current Site Role						
Import Site Role	SC	C	SE	EP	E	V	U
Site Administrator Creator (SC)	SC	SC	SC	SC	SC	SC	SC
Site Administrator Explorer (SE)	SE	SE	SE	SE	SE	SE	SE

	Current Site Role						
Import Site Role	SC	C	SE	EP	E	V	U
Creator (C)	SC	C	SE	C	C	C	C
Explorer (Can Publish) (EP)	SC	C	SE	EP	EP	EP	EP
Explorer (E)	SE	C	SE	EP	E	E	E
Viewer (V)	SE	C	SE	EP	E	V	V
Unlicensed (U)	SE	C	SE	EP	E	V	U

View, Manage, or Remove Users

Administrators can manage a site's users such as adding and removing users, setting the groups they're members of, setting their site roles, and so on. Server administrators can manage users on multiple sites at a time on the **All Sites** page.

View and manage users on a site

Sign in to a site as an administrator, and then select **Users**. On this page you can do any of the following to manage users:

- Set group membership, set site role, or remove the user from the site. If you've configured the site for SAML single sign-on, you can set the selected users' authentication type. If your server is configured for password policies and account access lockout, you can unlock access to a user's locked out account. If your server is configured for one or more **identity pools**, you can add or remove users.

- Select a user name to see details about them, such as content they own, views they subscribe to, and their account settings.

The user **Settings** page is available when the following conditions are true:

- The user is a member only of sites that the site administrator controls
- Site administrators can manage users by default. Tableau Server administrators can change this access for site admins.

If the server is configured to use the internal user management system (Local Authentication), you can edit the **Display Name**, **Email**, and **Password** for users after they have been added. If you are making many changes, you may find it easier to import the changes from a CSV file. For details, see [Import Users and CSV Import File Guidelines](#).

View and edit server users

Sign in to Tableau Server as a server administrator. On the site menu, select **Manage All Sites**, and then select **Users**.

Manage users' site membership

By default, server and site administrators can manage users at the individual site level. Server administrators can also manage users and their site roles on multiple sites. You do this at the **All Sites** level (at the server level).

1. In the site menu, select **Manage All Sites**, and then select **Users**.
2. On the Server Users page, select the check boxes next to the users, and then select **Actions > Site Membership**.
3. Select one or more sites, and a site role for each site, and then click **Save**.

Search for users (or groups or sites)

To search for a specific user (or group or site), use the filter toggle in the upper right to display the search box and site role filter. Then use the search box or filters to find the users (or group or site) you want. The search operation checks the display name and user name attributes.

The search box supports the wildcard (*) character. For example, searching for `John*` will return all names that start with *John*.

In addition:

- Starting in Tableau Server 2021.4.1, you can use the wildcard character (*) with a special character to search for names that contain special characters. For example, `sync-*` or `*sync-*`.
- Starting in Tableau Server 2022.1.13, when you search for names with diacritics, names must be entered with exact diacritics return relevant results. For example, to search for *José*, enter `José`. Searching for `Jose` will not return results.

- Starting in Tableau Server 2022.3.5, you can use the wildcard character (*) with AND or OR conditions when filtering users. For example, searching for **aw* AND John** returns all users whose names contain *aw* and whose names start with *John*.

The screenshot shows a user search interface. At the top right is a settings icon. Below it is a search bar containing the text "John*" with a magnifying glass icon on the left and a clear button (X) on the right. Underneath the search bar is a section titled "Advanced Filters". Within this section, there is a label "Site role" and a dropdown menu that currently displays "Any site role".

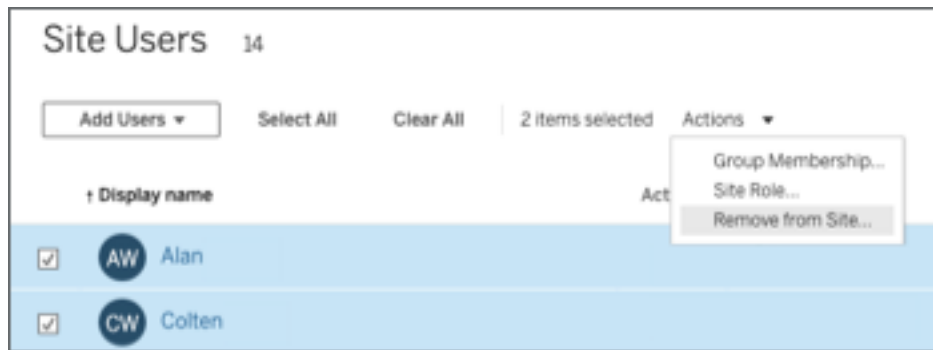

Remove users from a site

You can remove a user only if the user does not own any content (projects, workbooks, views, data sources, collections, or data alerts for example). If you attempt to remove a user who owns content, the user site role will be set to **Unlicensed**, but the user will not be removed.

If the default All Users group has enabled Grant site role on sign in, that user's content must be reassigned to another user or removed before they can be unlicensed or removed. For more information on Grant role on sign in, see [Removing users affected by Grant role on sign in](#). For more information on changing content ownership, see [Manage Content Ownership](#).

Note: On Tableau Server, when an administrator removes a user from a site (and the user belongs only to that one site), the user is also deleted from the server.

1. Sign in to a site as an administrator, and go to the **Users** area. Select one or more users to remove, and then select **Actions > Remove**.

2. Click **Remove** in the confirmation dialog.

Remove users from the server

You can remove a user only if the user does not own any content (projects, workbooks, views, or data sources). If you attempt to remove a user who owns content, the user site role will be set to Unlicensed, but the user will not be removed.

If a user is a member of multiple sites, and they own content on any of those sites, they are removed from the sites on which they don't own content. The user remains a member on sites where they own content, but demoted to the Unlicensed site role.

1. In the site menu, click **Manage All Sites**, and then click **Users**. In a single-site environment, click **Users**.

Select one or more users to delete, and then click **Actions > Delete**.

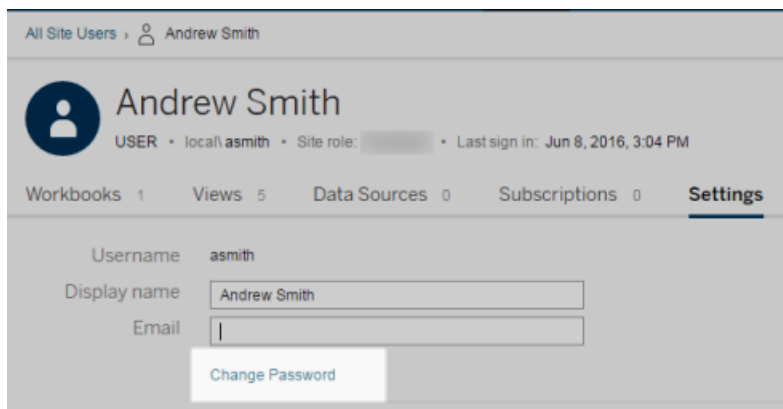

2. Click **Delete** in the confirmation dialog box.

Change passwords for users of a single site

To change the password for a user with membership to a single site, sign in to Tableau Server as a site administrator or a server administrator.

1. Ensure that the correct site is selected in the menu.
2. Click **Users**.
3. Click the display name of a user.
4. Click **Settings**.
5. Click the **Change Password** link, edit the password, and then click **Save Password**.

Change passwords for users of multiple sites

To change the password of a user with membership to multiple sites, sign in to Tableau Server as a server administrator.

1. In the site menu, click **Manage All Sites**.
2. Click **Users**.
3. Click the display name of a user.

4. Click the **Change Password** link, edit the password, and then click **Save Password**.

The screenshot shows the Tableau Server user settings page for a user named Andrew Smith. At the top, there is a breadcrumb trail: "All Server Users > Andrew Smith". Below this, the user's profile is displayed with a blue circular icon containing a white person silhouette. To the right of the icon, the name "Andrew Smith" is shown in a large font. Below the name, the text "USER • local\asmith • Max site role: [dropdown menu] • Last sign in: Jun 8, 2016, 3:04 PM" is visible. Under the profile information, the word "Settings" is displayed in a bold font. Below "Settings", there are three input fields: "Username" with the value "asmith", "Display name" with the value "Andrew Smith", and "Email" which is currently empty. At the bottom of the settings section, there is a button labeled "Change Password".

Set the User Authentication Type for SAML

On a site that has been configured for site-specific SAML, administrators can specify users' authentication type. For example, if Tableau Server was configured for site-specific SAML and server-wide SAML, administrators can specify which users authenticate with site-specific SAML and which users authenticate with server-wide SAML.

You can assign authentication type at the time you add users to Tableau Server, as well as any time afterward.

1. When you're signed in to the Tableau Server site, select **Users**.
2. On the **Site Users** page, select the check boxes next to the users you want to assign an authentication type.
3. On the **Actions** menu, select **Authentication**.

4. In the Authentication dialog box, select **Site SAML** or **Server Default**.

Notes

- Users that authenticate with site-specific SAML can only belong to one site. If a user needs to belong to multiple sites, set their authentication type to the server default. Depending on how site-specific SAML was configured by the server administrator, the server default is either local authentication or server-wide SAML.
- If you change users' authentication to site-specific SAML, the next time they sign in, they will be directed to your identity provider's site to provide their credentials.

Import Users

To automate the process of adding users to a site, you can create a CSV file that contains user information, and then import the file.

Site administrators can import users to a particular site; server administrators (Tableau Server only) can import users at the server level, to later add them to multiple sites.

Note: This topic contains the steps for importing, assuming that you have already created the CSV file. If you have not created the file yet, see [CSV Import File Guidelines](#) for a list of file format requirements and import options.

Add users from a CSV file

The following steps describe how to add users to a site or to the server. The images reflect adding users at the site level.

1. Do one of the following:
 - To add users at the site level, select **Users**, and then **Add Users**.

- To add users at the server level on a **single-site** server, select **Users**, and then **Add Users**.
 - To add users at the server level on a **multi-site** server, open the list of sites, and select **Manage All Sites**. Select **Users**, and then **Add Users**.
2. Click **Import From File**, click **Browse** and navigate to the file, and then click **Import Users**.

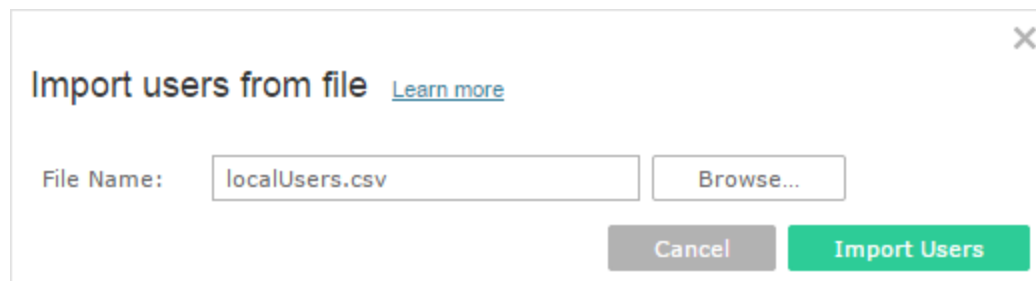

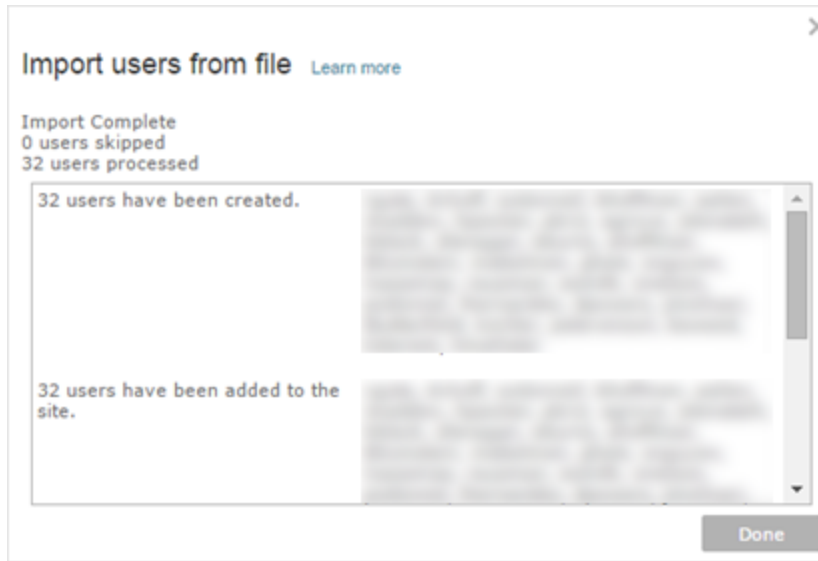

Tableau displays the results of the import process (names in this image are blurred).

3. Click **Done**.

How users' site roles are assigned or maintained

When you import at the site level or on a single-site server using `tabcmd`, you can specify the site role for all users in the CSV file. If a user already exists in the Tableau Server site, the site role assigned during the import process will be applied, even if it is more restrictive than users' existing site role. The exception is that you cannot affect a server administrator's site role.

For a multi-site server, when you import users in the Server Users page, you create server users with no site affiliation. Because these users do not belong to a site, they cannot have a site role. The only site role a user can have at the server level is **Unlicensed** or **Server Administrator**.

You can also specify the user's site role when you assign site membership to a user. For information, see [Manage users' site membership](#).

Importing at the server level in multi-site environments

If the server is running multiple sites and you are a server administrator, you can import a CSV file from two locations. Where existing user accounts are concerned, each location has different capabilities.

- The **Server Users** page appears in a multi-site environment. Only server administrators can access this page.

	† Display name	Username	Max site role	Sites	Last signed in
<input type="checkbox"/>	Adam Davis	adavis	Site Administrator	7	Jul 21, 2016, 5:12
<input type="checkbox"/>	Admin	Admin	Server Administrator	9	Aug 5, 2016, 9:19
<input type="checkbox"/>	Alejandro Grove	agrove	Interactor	1	

You can import the CSV file from here if you want to update existing user accounts in addition to adding new ones. For example, if you import a file that has a new password for each existing user, their passwords will be reset.

- The **Site Users** page.

	† Display name	Username	Site role	Groups	Last signed in
<input type="checkbox"/>	Adam Davis	adavis	Site Administrator	2	Jul 21, 2016, 5:12
<input type="checkbox"/>	Admin	Admin	Server Administrator	3	Aug 5, 2016, 9:19
<input type="checkbox"/>	Andrew Allen	aallen	Publisher	2	Jul 21, 2016, 5:35

Server administrators can add new user accounts with CSV imports. If the CSV file includes existing users, the **Password** and **Display Name** fields must either match the existing or be left blank. If new passwords or full names are used, the import will fail.

Importing to a single-site environment

Server and site administrators on a single-site server perform CSV user imports from the **Users** page in a site.

The screenshot shows the 'Users' page in Tableau. At the top, it says 'Users 57'. Below this is a search bar and a '+ Add Users' button. To the right of the button, it says '0 selected'. Below the search bar is a 'General Filters' section with a 'Site role' dropdown menu set to 'Any site role'. The main part of the page is a table with the following columns: 'Display name', 'Username', 'Site role', 'Groups', and 'Last signed in'. The table contains three rows of user data.

	† Display name		Username	Site role	Groups	Last signed in
<input type="checkbox"/>	 Adam Davis	...	adavis	Site Administrator	4	May 13, 2016
<input type="checkbox"/>	 Admin	...	Admin	Server Administrator	2	Aug 5, 2016
<input type="checkbox"/>	 Alan Wang	...	awang	Publisher	4	

Multi-site versus single-site import

Users can belong to more than one site on the same server, but they must use the same credentials for each site. This becomes important when you're adding users to a site and those users might already be members of a different site. If you try to import a user who already exists, and if the user's credentials in the CSV file don't match the existing credentials, the import fails for that user.

If you're importing users to a site and think the users might already exist on the server, you can try leaving the **Password** field in the CSV file blank (while including the delimiters for the field). If a user who is defined in the CSV already exists in another site, the user is added to the site where you're importing. However, if the user *doesn't* already exist on the server, the user is created, and the CSV import window alerts you that the new user doesn't have a password. You can then use the server administrator pages to assign a password to any user who doesn't have one.

Note: If the server is configured to use Active Directory for authentication, user passwords are managed by Active Directory, and you can leave the password field in the CSV file blank.

CSV Import File Guidelines

You can automate adding users by creating a comma-separated values (CSV) file with user information and then importing the file. You can include attributes in the CSV file, such as license level and the publishing access, to apply to the users at the same time you import them.

To import users, you can use the server or site administration pages or the `tabcmd` utility. Using `tabcmd` provides an option for assigning a site role to all users in the CSV file. For information, see [Import Users](#) or `createsiteusers filename.csv`.

You can import users at the site or server level. If you import users to the server (not to a specific site), the users aren't assigned to a site and are imported as Unlicensed.

Note: Unless otherwise noted, the guidelines specified in this topic apply to Tableau Server when configured with or without [identity pools](#).

CSV file format requirements

When you create the CSV file for importing users, make sure that the file meets the following formatting requirements:

- The file does not include column headings. Tableau Server assumes that every line in the file represents a user.
- The file is in UTF-8 format, and includes the byte-order mark (BOM).
- Character encodings such as BIG-5 have been converted to UTF-8. You can do this by opening the file in a text editor and using the **Save As** command.

- If a user name includes an @ character that represents anything other than a domain separator, you need to refer to the symbol using the hexadecimal format: \0x40

For example, `user@fremont@mycompany.com` should be `user-\0x40fremont@mycompany.com`

Required columns in the CSV file

The following values are required for each user:

- User name
- Password: If Tableau Server is configured to use Active Directory authentication, there must be a `Password` column, but the column itself should be empty. If the server is using local authentication, you must provide passwords for new users.

Additional import file options

The CSV file can contain the following fields, in the order shown here:

- User name. The user name. If the server is configured to use Active Directory, this value must match a user defined in Active Directory. If the user name is not unique across domains, you must include the domain as part of the user name (for example, `example\Adam` or `adam@example`). **This is the only required field.**

If adding users to an **identity pool**, make sure of the following:

- If adding a user to an identity pool that uses AD as its identity store, make sure to use the AD `sAMAccountName` value for user name.
- If adding a user to an identity pool that uses LDAP as its identity store, make sure to use the LDAP `username` value for user name.
- Password. A password for the user. If the server is configured to use Active Directory, this value is not used.

- **Display name.** The display name is part of the information used to identify a user on the server. If the user's display name is already in use, Tableau Server updates the existing user information with the settings in the CSV file. If the server is configured using Active Directory, this value is not used.
- **License level.** This can be **Creator**, **Explorer**, **Viewer**, or **Unlicensed**. If you specify **Creator** for a particular user account, then you must also set the Publishing capability to **True**.
- **Administrator level (**System**, **Site**, or **None**).** This setting determines whether the user is imported as an administrator.

If you are using the web UI to import users, you can set the administrator site role to **System** only if you import the file at the server (All Sites) level. If you are signed in to a specific site, and if the administrator column for a user in the CSV file is set to **System**, Tableau Server imports the user as a site administrator.

- **Publishing capability (**yes/true/1** or **no/false/0**).** If you are using the web UI, the publisher setting is used only if you import while signed in to a specific site.
- **Email address.** The email address is part of the information used to identify a user on the server. If the email address is already in use, Tableau Server updates the existing user information with the settings in the CSV file.

If adding users to an identity pool, the following values are needed in addition to the above:

- **Identity pool name.** The name of the identity pool that you want to add the user to.
- **Identifier.** The identifier for the user you want to add. Identifiers are only used for identity matching purposes. For more information, see [Usernames and identifiers in Tableau](#).

Notes:

- If you are adding users to an identity pool and you don't specify the identity pool name, users are added to the initial pool (TSM configured), which is the set of

users who were provisioned in TSM during Tableau Server setup.

- For the user name value, make sure of the following:
 - If adding a user to an identity pool that uses AD as its identity store, make sure to use the AD sAMAccountName value for user name.
 - If adding a user to an identity pool that uses LDAP as its identity store, make sure to use the LDAP username value for user name.

Important: The order of the columns is significant. The first column is treated as the user name, the second as the password, the third as display name, and so on, regardless of the content in the columns. If you omit values for a field, you must still include the field's comma delimiter.

Improve performance for large CSV files passed through `tabcmd`

Note: These settings apply to Tableau Server version 2022.1 and earlier. The search and index service they affect was deprecated starting in version 2022.3 and retired (removed completely) in 2023.3.

A server administrator can enable server settings that help to improve performance for importing large CSV files through `tabcmd` commands. You can do this using the `tsm configuration set` command with the following options:

- `vizportal.csv_user_mgmt.index_site_users`
- `vizportal.csv_user_mgmt.bulk_index_users`
- `searchserver.index.bulk_query_user_groups`

Essentially, these options index users after the CSV file is processed, instead of one-by-one as they are added to the server's database. This reduces the number of calls to the database and the memory required to process the file. These `tsm configuration set` options apply to the `tabcmd createsiteusers`, `deletesiteusers`, `addusers`, and `removeusers` commands.

For descriptions for these settings, see tsm configuration set Options.

Notes

- If you are not signed in to a specific site and are importing users at the server level, you can assign only the Server Administrator and Unlicensed site roles.
- If you have a user-based server installation, and if adding users would exceed the number of users allowed by your license, the users are added as unlicensed users.
- If you use `tabcmd` and specify the license, but importing users would exceed your license limits, users are imported as Unlicensed.

CSV settings and site roles

The license level, administrator, and publishing settings for a user determine how the user's site role is set during the import process. The following table shows how the settings are converted to site roles.

CSV settings	Site role
License level=(any) Administrator=System Publisher=true	<p>Server Administrator. This setting applies to Tableau Server only, and it is valid only if you are importing users while managing the server (that is, not signed in to a specific site).</p> <p>The Server Administrator site role always takes a Creator license if one is available. If no Creator license is available, see Troubleshoot Licensing to learn about the way Tableau Server handles this.</p>
License level=Creator or Explorer Administrator=Site Publisher=true	<p>Site Administrator Creator or Site Administrator Explorer. This setting is valid only if you are importing users while signed in to a specific site.</p>

CSV settings	Site role
License level=Creator Administrator=None Publisher=true	Creator
License level=Explorer Administrator=None Publisher=true	Explorer (Can Publish)
License level=Explorer Administrator=None Publisher=false	Explorer
License level=Viewer Administrator=None Publisher=false	Viewer
License level=Unlicensed Administrator=None Publisher=false	Unlicensed

CSV import example for Tableau Server

The following example shows a CSV file that contains information for several users.

```
henryw,henrypassword,Henry Wilson,Creator,
None,yes,henryw@example.com
freds,fredpassword,Fred Suzuki,Viewer,None,no,freds@example.com
alanw,alanpassword,Alan Wang,Explorer,Site,yes,alanw@example.com
```

```
michellek,michellepassword,Michelle Kim,Creat-
or,System,yes,michellek@example.com
```

If you import this file while managing a site, four users are added to that site. The `Administrator` setting for user Michelle is `System`. However, because you are importing the users into a site, Tableau Server give Michelle the Site Administrator Creator site role. Three of the users are allowed to publish.

If you import this file while managing the server, four users are added to the server, but they are not added to any site. Only one user is imported as a server administrator; the rest are set to `Unlicensed`.

The following example shows a CSV file that contains information for two users added to an identity pool.

```
henryw,henrypassword,Henry Wilson,View-
er,None,yes,hwilson@myco.com,General Contractors,hwilson
freds,fredpassword,Fred Suzuki,Creat-
or,None,no,fsuzuki@myco.com,General Contractors,fsuzuki
```

Manage Site User Visibility

By default, all site users can see aliases, project ownership and comments by other users when permissions allow. The User Visibility setting lets administrators manage if users with Viewer and Explorer site roles see other users and groups on the site, which can be important for sites that are used by multiple clients. To learn more about site roles, see [Set Users' Site Roles](#).

Limit user visibility

Setting User Visibility to **Limited** impacts certain collaboration tools and hides user information in Tableau Cloud and Tableau Server. Limited User Visibility either disables the feature for Viewers and Explorers (excluding Site Administrator Explorers), or removes user information from other areas. Note that Creators and administrators will still see user information when User Visibility is set to Limited.

To limit user visibility for Explorers and Viewers (excluding Site Administrator Explorers):

- Navigate to the site's **Settings** page
- Select **Limited** in the **User Visibility** setting

The following is a list of site areas impacted when User Visibility is set to Limited. Unless noted that the feature is disabled for all users, only non-administrator Explorers or Viewers are impacted.

Area	Impact
Search	User information not displayed
Content owners	User information not displayed (Explorers and Viewers can't see themselves, but can see their content in My Content)
Profile pictures	User information not displayed
Subscriptions	User information not displayed
Recommendations	Similar users not displayed (all users)
Add/Edit Tags	Explorers and Viewers can see tags but cannot delete or modify them
"Who has seen this view?"	Disabled
Ask Data usage analytics	Disabled
Permissions dialogs	Disabled
Named sharing	Disabled (all users)
Alerts	Disabled (all users)
	Existing alerts paused

Comments	Disabled (all users)
Public Custom Views	Disabled (all users)
	Existing public custom views appear as private
Request Access	Disabled (all users)
Tableau Desktop	Publishing workbooks disabled from Desktop
	User information not displayed on user filters
Tableau Catalog (with Data Management)	User information not displayed

When User Visibility is set to Limited, Tableau Server REST API and Metadata API calls behave as described in the table above.

Users on a site can interact with views and modify them, such as applying filters. If that user shares their modified view with others, or if the user creates something from that modified view (like a metric or a private custom view), then that user's name appears in the URL. Make sure that the URL for this modified view is only distributed to users who are permitted to see that person's name.

Note: If a user is a member of multiple sites, entering an email on the sign in page for Tableau Cloud will return the names of all sites the user is a member of.

Best practices for limiting user visibility

Administrators can also check that user and group information is not visible in these ways:

- Configure permissions to only provide content to appropriate parties. For more information, see [Permissions](#).
 - Limited User Visibility hides user identification information from search, but might return content that the user published, including when searching by owner name, if the person searching has viewing permission to that content.

- A user publishing a workbook with a duplicate title in the same project might see a warning that a workbook with that title already exists.
- Apply row-level security when necessary.
- Check that metadata within dashboards does not contain user information.
- Check that calculations accessible to users don't contain user metadata (e.g., user filters).

Restore Full User Visibility

When administrators set User Visibility back to Full, features disabled for all users by Limited User Visibility (such as comments and alerts) remain off. Administrators can re-enable these features through the site's Settings page.

Any previous feature settings are not retained when User Visibility is set to Full, and affected features are not automatically turned on.

Guest User

Core-based licenses of Tableau Server include a Guest user option, which you can use to let people access Tableau views without an account on the server.

Guest user access is enabled by default when Tableau Server is installed with a core-based license. It is not available with user-based licensing. If you do not intend to use Guest user access, you should disable it.

Guest access allows users only to see and interact with Tableau views. The Guest user cannot browse the Tableau Server interface or see server interface elements in the view, such as user name, account settings, comments, and so on. For more information about licenses, see [Manage Licenses](#).

Tip: To share views with Guest users, either provide URL links or embed views into web pages. For more information, [see Tableau User Help](#).

Guest user permissions

A Guest user can have the following maximum capabilities:

- **Workbooks and views:** View, Export Image, Summary Data, View Comments, Filter, Full Data, Web Edit, Download (to save a local copy)
- **Data sources:** View and Download

If you add the Guest user to a group that has a higher level of access to a content resource, the Guest user's access does not exceed the capabilities listed above. However, the Guest user account will comply with more restrictive permissions settings.

The Guest user can only access data with embedded credentials or where credentials are not required. A data source that prompts the user for credentials cannot be accessed by the Guest user. See [Data access for published Tableau data sources](#).

Enable or disable Guest access

You must be a server administrator to change Guest account settings at either the server or the site level.

Note: Enabling the Guest user for a site can increase the number of potential simultaneous viewers beyond the user list you might be expecting. The administrative view **Status > Traffic to Views** can help you gauge the activity.

1. In the site menu, click **Manage All Sites** and then click **Settings > General**.
2. For **Guest Access**, select or clear **Enable guest access**.
3. Click **Save**.

This enables the Guest user on all sites. You can then go to the same setting for a specific site. To disallow Guest access for a site:

1. In the site menu, select a site.
2. Click **Settings**, and on the General tab, clear the **Enable guest access for this site** check box.

If the Guest account is enabled on some or all sites, and you turn off Guest access at the server level, it is turned off for all sites as well.

Note: You can turn off Guest user access at the server or site level; however, you aren't able to remove the user. So, although no one can access data or views without signing in to the server, the Guest user still appears in the Site Users list and group lists for groups you've added the Guest user to.

Additional Guest account characteristics

The Guest user is unique in the following additional ways:

- As a single user account, it represents all unauthenticated users accessing Tableau views.
- When enabled, it is a member of the All Users group.
- You can add it as a member of other groups on a site.
- You cannot edit it or select it as the owner of a content resource.
- The account is not allowed to save custom views.
- Guest cannot be used in a user filter.
- You cannot delete the account; however, you can turn off access to it by clearing the check box described in the steps above.

Groups

You can create and delete user groups, add users to a group, and synchronize groups with Active Directory.

Add Users to a Group

You can organize Tableau Server users into groups to make it easier to manage multiple users. You can create groups on the server or import groups from Active Directory.

If you're managing users with an External identity store, such as Active Directory, add users to a group through the external identity store itself. Once users are added to a group in the

external identity store, Tableau Server is able to update those users by synchronizing the group of users in the external identity store with the group of users on Tableau Server.

For example, to keep Active Directory group membership up to date, we recommend you review the following:

- Site administrators can synchronize selected groups on demand in a site. For more information, see [Synchronize Active Directory Groups on a Site](#).
- Server administrators can synchronize all Active Directory groups on the server based on a schedule or on-demand. For more information, see [Synchronize All Active Directory Groups on the Server](#).

Notes:

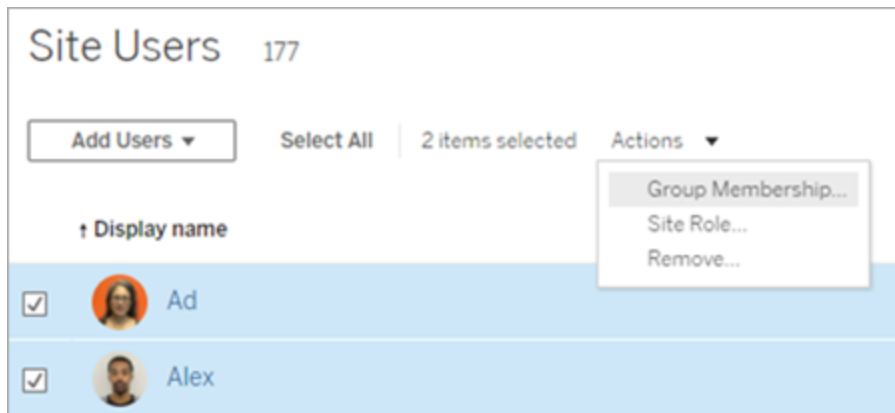

- In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions. When identity pools are configured, you cannot add groups to an identity pool.
- Adding groups to an **identity pool** is not supported. Only individual users can be added to an identity pool.

If you're managing users with a Local identity store, use the procedures described below to add users to a group.

To add a user to a group, the group must already exist.

Add users to a group (Users page)

1. In a site, click **Users**.
2. Select the users you want to add to a group, and then click **Actions > Group Membership**.

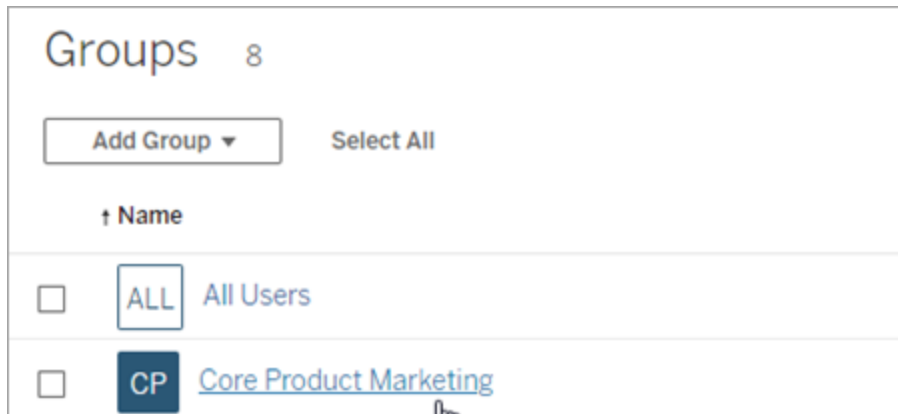

3. In the Group Membership dialog box, select the groups and then click **Save**.

Add users to a group (Groups page)

Note: This is only possible for site administrators if the server administrator has configured the site so that both Server and Site administrators can manage users. For more information, see [Managing Users \(Tableau Server Administrators only\)](#).

1. In a site, click **Groups**, and then click the name of the group.

2. In the group's page, click **Add Users**.

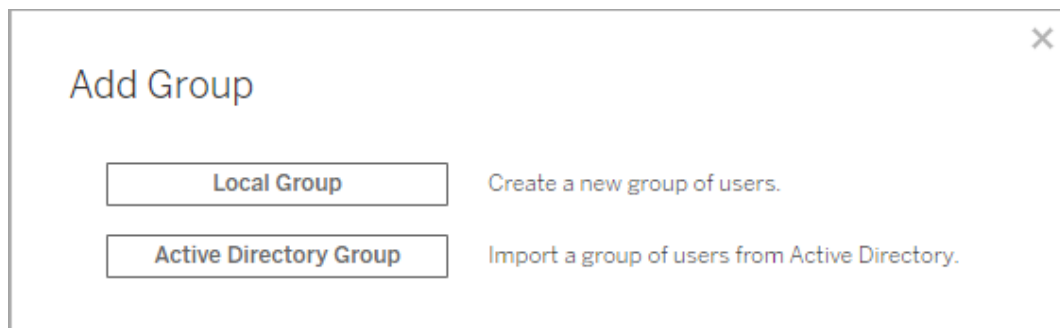

3. In the Add Users dialog box, select the users to be added, and then click **Add Users**.

Create a Local Group

Local groups are created using the Tableau Server internal user management system. After you create a group you can add and remove users, as well as set a minimum site role to grant to users in the group when they sign in.

1. In a site, click **Groups**, and then click **Local Group**.

2. Type a name for the group.
3. To set a minimum site role for the group, select **Grant site role on sign in** and select a minimum site role from the drop-down list.

4. Click **Create**.

Create Groups via Active Directory

You can import Active Directory (AD) groups to create matching groups on Tableau Server, as well as a user for each member of an AD group that is not already on the server.

Note: In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

Each user is assigned a site role as part of the import process. If any of the users to be imported exist in Tableau Server, the site role assigned during the import process is applied only if it gives the user more access to the server. Importing users does not demote site roles.

Before you begin

Before importing groups, review User Management in Deployments with External Identity Stores to understand how multiple domains, domain naming, NetBIOS, and Active Directory user name format influence Tableau user management.

Import from AD to add a group

As part of adding a user group to Tableau Server, you import a group from Active Directory (AD). When importing a group, you first enter the group name to search for the group.

Entering a group name, by default, causes Tableau Server to perform a wildcard query (for example, *marketing*) against AD (or LDAP) to maximize the search results. If you're working against a large AD (or LDAP) identity store, you might experience a timeout before you can successfully select the group to import.

To help save time and avoid potential timeout issues during the import process, consider searching a group name using one of the following methods:

- **Exact match:** The most efficient method for searching a group name, enter the exact group name by including quotation marks (") preceding and following the string you enter. For example, **"marketing"**.
- **Partial match:** Enter a part of the group name and include an asterisk (*) preceding and following the string you enter. For example, ***ket***.
- **Begins with:** Enter the beginning portion of the group name followed by an asterisk (*). For example, **market***.
- **Ends with:** Enter an asterisk (*) followed by the ending portion of the group name. For example, ***ing**.

Note: These methods also apply to how Tableau Server searches for users.

1. In a site, click **Groups**, and then click **Add Groups**.
2. Type the name of the Active Directory group you want to import, and then select the group name in the resulting list. Use one of the filtering methods above to improve performance.

If you're importing a group from the same AD domain that the server is running on, you can type the AD group name without the domain. The server's domain will be assumed.

The screenshot shows a dialog box titled "Import a Group from Active Directory". Below the title is a subtitle: "Import a group of users from Active Directory." There is a text input field containing the word "marketing". Below this field is a list box containing the word "Marketing", which is highlighted with a blue background. At the bottom of the dialog, there is a "Site role" dropdown menu set to "Explorer (can publish)" with an information icon to its right. Below the dropdown is a checkbox labeled "Grant role on sign in" which is currently unchecked. At the bottom right are two buttons: "Cancel" and "Import".

3. Select the minimum site role for the users.

4. (Optional) Select **Grant role on sign in** to provision new site roles and licenses when group users sign in. For more information, see [Grant License on Sign In](#).
5. Click the **Import** button.

Note: You cannot change the name of groups imported from Active Directory. The group name can only be changed in Active Directory.

Synchronize External Directory Groups in a Site

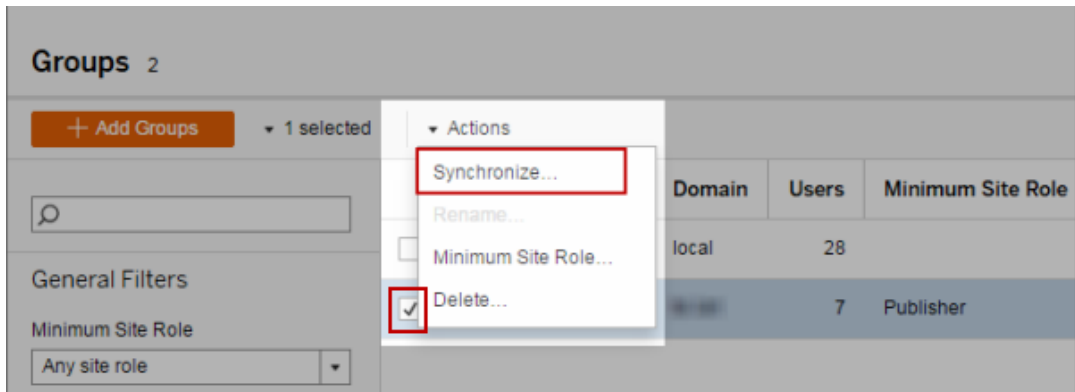

At any time, you can synchronize an external directory (such as Active Directory) group with Tableau Server to ensure new users in the external directory are also added in Tableau Server. You can synchronize individual groups or multiple groups at once.

Note: In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

1. In a site, click **Groups**.

On the Groups page, select one or more groups.

2. Click **Actions > Synchronize**.

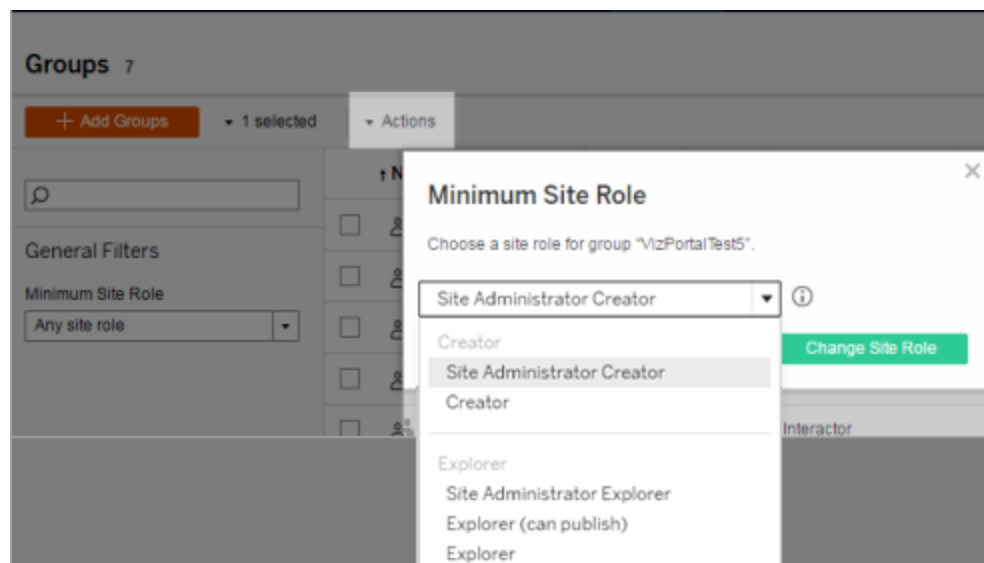

Set the minimum site role for users in an external directory group

In the **Groups - Details** page, administrators can set the minimum site role for group users to apply during synchronization.

This setting does not run synchronization; it sets the minimum site role to applied to the group every time synchronization runs. When you synchronize external directory groups, new users are added to the site with the minimum site role. If a user already exists, the minimum site role will be applied if it gives the user more access in a site. If you don't set a minimum site role, new users are added as **Unlicensed** by default.

Note: A user's site role can be promoted but never demoted based on the minimum site role setting. If a user already has the ability to publish, that ability will always be maintained. For more information on minimum site role, see Site roles and Active Directory import and synchronization.

1. In a site, click **Groups**.
2. On the Groups page, select a group, and then select **Actions > Minimum Site Role**.
3. Select the minimum site role, and then click **Change Site Role**.

What happens when users are removed in the source external directory?

Users cannot be automatically removed from the Tableau Server through an external directory sync operation. Users that are disabled, deleted, or removed from groups in the

external directory remain on Tableau Server so that administrators can audit and reassign the user's content before removing the user's account completely. For more information, see Sync behavior when removing users from Active Directory.

What happens when a user name changes in the source external directory

By default, Tableau Server will not synchronize changes to the user display name or email address after the initial synchronization when the corresponding account is created in Tableau Server. For example, if the user name `jsmith` is used for the display name John Smith, changing the display name in external directory to Joe Smith will not synchronize to the corresponding `jsmith` user in Tableau Server. Similarly, if the user's email changes in the external directory, Tableau Server will not synchronize changes.

You can configure Tableau Server to update the name and email properties when they change in the source external directory by setting `vizportal.adsync.update_system_user` to `true`.

To change this behavior run the following `tsm` commands:

```
tsm configuration set -k vizportal.adsync.update_system_user -v true
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

What happens when an external directory group is removed from Tableau Server?

Many Tableau administrators use external directory groups to import and create users. After the users are imported into Tableau Server, administrators will then delete the group in Tableau Server. Deleting a group does not delete the users in it.

Synchronize External Directory Groups on the Server

As a server administrator, you can synchronize all external directory (such as Active Directory) groups (that have been configured on Tableau Server) on a regular schedule or on-demand on the **General** tab of the **Settings** page for the server.

Active Directory Synchronization

Synchronize All Groups...

☒ Synchronize Active Directory groups on a regular schedule

Frequency ☐ Hourly ☒ Daily ☐ Weekly ☐ Monthly

at 12 : 00 AM

Note: In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

Before you begin

Before synchronizing groups as described in this topic, you must first import the external directory group into Tableau Server. See [Create Groups via Active Directory](#).

Synchronize external directory groups on a schedule

1. **Single-site:** Click **Settings**> **General**.

Multisite: In the site menu, click **Manage All Sites** and then click **Settings**> **General**.

2. Scroll down the page to **Active Directory Synchronization**, and then select **Synchronize Active Directory groups on a regular schedule**.

Active Directory Synchronization

[Synchronize All Groups...](#)

☒ Synchronize Active Directory groups on a regular schedule

Frequency ☐ Hourly ☒ Daily ☐ Weekly ☐ Monthly

at 12 : 00 AM

3. Select the frequency and time of synchronization.
4. Click **Save**.

Note: Beginning in versions 2021.1.23, 2021.2.21, 2021.3.20, 2021.4.15, 2022.1.11, 2022.3.3, 2023.1, a default time limit of 4 hours limits how long a scheduled group synchronization can take before it is canceled. A server administrator can change this time limit if your scheduled synchronization is of very large groups, or taking longer than the default. For more information, see [Synchronize All Active Directory Groups on a Schedule](#) and `backgrounder.timeout.sync_ad_group`.

Synchronize all external directory groups on demand

At any time, you can synchronize external directory (such as Active Directory) groups with Tableau Server to ensure that new users and changes in the external directory are reflected in all external directory groups on Tableau Server.

1. **Single-site:** Click **Settings> General**.

Multisite: In the site menu, click **Manage All Sites**, and then click **Settings> General**.

Active Directory Synchronization

Manage the synchronization of all Active Directory groups. [Learn more](#)

Last synchronized: (Server time)

[View synchronization activity](#)

Synchronize All Groups...

☒ Synchronize Active Directory groups on a regular schedule

Frequency ☐ Hourly ☒ Daily ☐ Weekly ☐ Monthly

at 12 : 00 AM

2. Under **Active Directory Synchronization**, click **Synchronize All Groups**.

View synchronization activity

You can view the results of synchronization jobs in the **Background Tasks for Non Extracts** administrative view. **Queue Active Directory Groups Sync** is the task that queues and indicates the number of **Sync Active Directory Group** tasks to be run.

1. **Single-site:** Click **Status**.
- Multisite:** In the site menu, click **Manage All Sites** and then click **Status**.
2. Click the **Background Tasks for Non Extracts** link.
3. Set the **Task** filter to include **Queue Active Directory Groups Sync** and **Sync Active Directory Group**.

You can quickly navigate to this administrative view by clicking the **View synchronization activity** link in the **Settings** page for the server.

Set the minimum site role for users in an external directory group

In the **Groups - Details** page, you can set the minimum site role for group users to be applied during Active Directory synchronization.

This setting does not run synchronization; instead, it sets the minimum site role to applied to the group every time synchronization runs. The result is that when you synchronize external directory groups, new users are added to the site with the minimum site role. If a user already exists, the minimum site role is applied if it gives the user more access in a site. If you don't set a minimum site role, new users are added as **Unlicensed** by default.

Note: A user's site role can be promoted but never demoted based on the minimum site role setting. If a user already has the ability to publish, that ability will always be maintained. For more information on minimum site role, see Site roles and Active Directory import and synchronization.

1. In a site, click **Groups**.
2. On the Groups page, select a group.

Click **Actions > Minimum Site Role**.

3. Select the minimum site role, and then click **Change Site Role**.

What happens when users are removed in the source external directory?

Users cannot be automatically removed from the Tableau Server through an external directory sync operation. Users that are disabled, deleted, or removed from groups in the external directory remain on Tableau Server so that administrators can audit and reassign the user's content before removing the user's account completely. For more information, see [Sync behavior when removing users from Active Directory](#).

Improving group synchronization performance

External directory synchronization is performed by the backgrounder process. The Backgrounder process is the same process that is used for managing and creating extracts, and is also used to generate subscription content. In large organizations with dynamic group membership and heavy extract usage, the external directory group synchronization process may be disruptive. We recommend running group synchronization during non-business hours.

By default, the Backgrounder process performs synchronization in a serial operation. This means that each group is synchronized, one after the other, in a single Backgrounder process. If you are running multiple instances of Backgrounder processes either on a single Tableau Server or across a distributed deployment, consider enabling parallel processing for external directory synchronization. When parallel Backgrounder processing is enabled, the group synchronization is distributed across multiple Backgrounder processes for better performance.

To enable parallel backgrounder processing for group synchronization, open TSM CLI and enter the following commands:

```
tsm configuration set -k backgrounder.enable_parallel_adsync -v  
true
```

```
tsm pending-changes apply
```

Synchronize All Active Directory Groups on a Schedule

After you import Active Directory groups in Tableau Server, you can make sure they stay synchronized in Tableau Server by setting up a schedule. You can also synchronize all Active

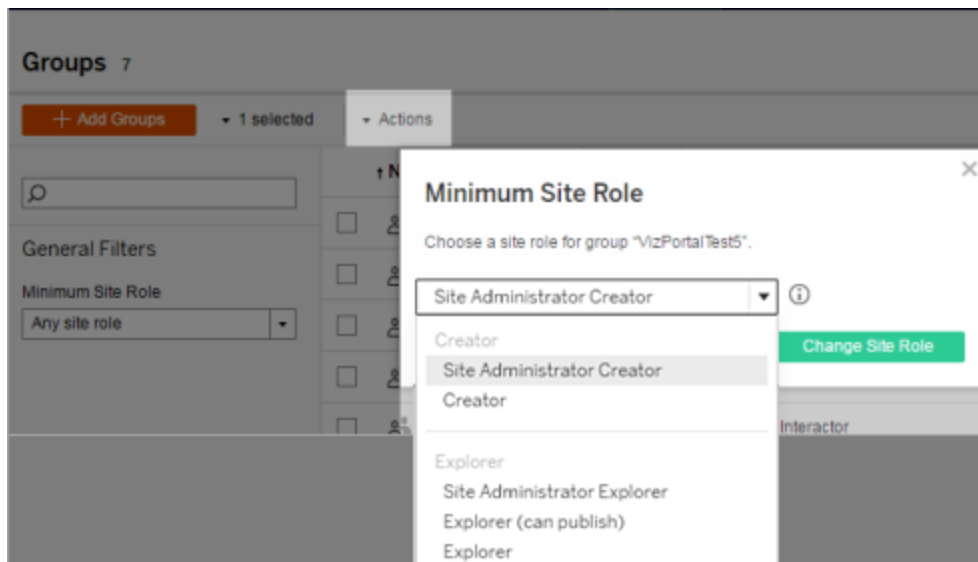

Directory groups on the server on-demand, at any time. The minimum site role setting for the group is applied when users are synchronized.

Note: In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

Beginning in versions 2021.1.23, 2021.2.21, 2021.3.20, 2021.4.15, 2022.1.11, 2022.3.3, 2023.1, you can set a maximum time limit for how long a scheduled group synchronization can take before it gets canceled. The default time limit is 4 hours. For more information, see `backgrounder.timeout.sync_ad_group`.

1 Set a minimum site role for synchronization

In a site, click **Groups**. Select a group, and then click **Actions> Minimum Site Role**. Select the minimum site role, and then click **Change Site Role**. Server and site administrators can set the minimum site role for group users to be applied during Active Directory synchronization. If you don't set a minimum site role, new users are added as **Unlicensed**.

Synchronizing can promote a user's site role, but will never demote a user's site role.

2 Set the schedule

Server administrators can enable synchronization for all Active Directory groups on the **General** tab of the **Settings** page for the server. Enable synchronization, select the frequency settings, and then click **Save**.

The screenshot shows the 'General' tab of the Tableau Server Settings page. At the top, there are two tabs: 'General' (selected) and 'Licenses'. Below the tabs are 'Revert' and 'Save' buttons. The main section is titled 'Active Directory Synchronization' and includes a link to 'Manage the synchronization of all Active Directory groups. Learn more'. It shows the 'Last synchronized' time as 'Aug 4, 2016, 4:29 PM (Server time)' and a link to 'View synchronization activity'. A 'Synchronize All Groups...' button is present. Below this, there is a checkbox labeled 'Synchronize Active Directory groups on a regular schedule' which is checked. Underneath, the 'Frequency' is set to 'Daily' (selected with a radio button). The time is set to 'at 12 : 00 AM' using dropdown menus.

All Active Directory groups on the server are synchronized according to the same schedule.

3 Run synchronization on-demand (optional)

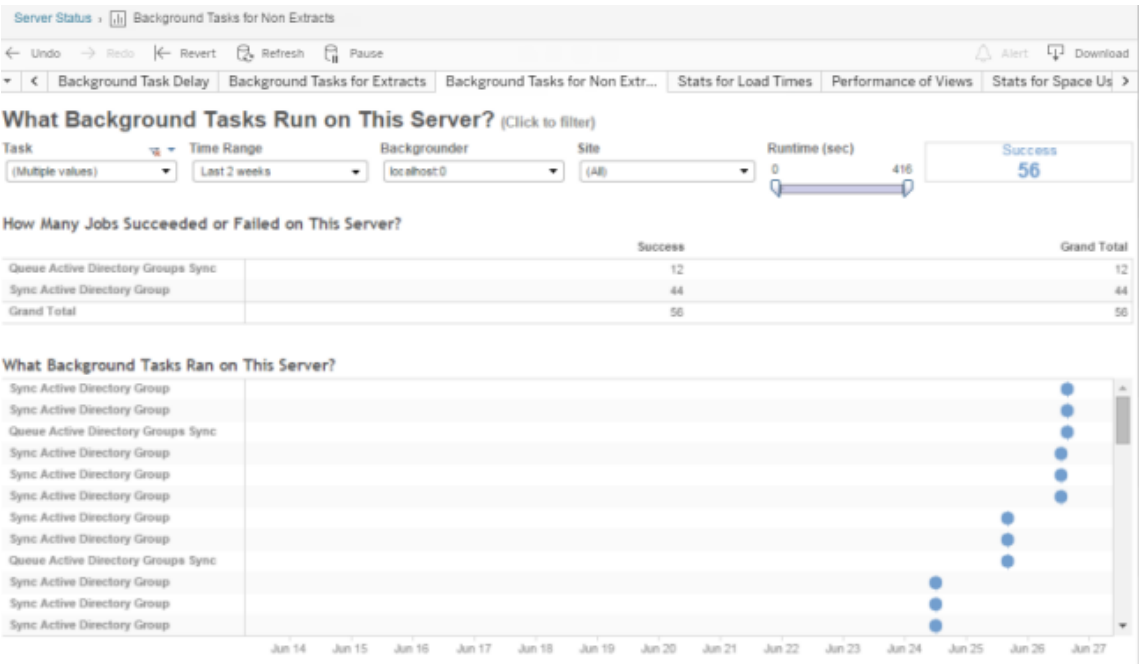

On the **General** tab of the **Settings** page, click **Synchronize All Groups** to synchronize all Active Directory groups on Tableau Server immediately. Click this button at any time to ensure new users and changes are reflected in all Active Directory groups on the server.

Click **Synchronize All Groups** to synchronize all Active Directory groups on the server outside of a schedule.

4 View the status of synchronization tasks

Server and site administrators can view the results of Active Directory synchronization jobs in the **Background Tasks for Non Extracts** administrative view. On the server or in a site, click **Status**. Under **Analysis**, click **Background Tasks for Non Extracts** and filter on the **Queue Active Directory Groups Sync** and **Sync Active Directory Group** tasks.

Queue Active Directory Groups Sync queues the **Sync Active Directory Group** tasks to be run.

Grant License on Sign In

Grant license on sign in (Grant role on sign in) lets unlicensed users in specific groups become licensed when they sign into a Tableau site. This streamlines license provisioning for administrators and removes the user's need to request a license before using Tableau.

For more information about site role capabilities and minimum site roles, see [Set Users' Site Roles](#).

For example, imagine an Active Directory group called Marketing with 100 users, but only 25 users need to access Tableau Server. A site or server administrator can import all users in the Marketing Active Directory group, set the group's minimum site role to Explorer, and select **Grant role on sign in**. When any of the Tableau users in Marketing sign into their Tableau site, they'll be granted Explorer licenses. Users who don't need Tableau Server remain unlicensed unless they sign in.

Note: For more information about benefits and best practices, see [Grant Role on Sign In](#) in Tableau Blueprint, Tableau's planning tool for data-driven organizations.

Activate Grant role on sign in

You can enable Grant role on sign in on new or existing groups. The following steps walk through how to use Grant role on sign in to add new users that are eligible for a license but may not consume one. This may be the case when your company has a lot of eligible users, but limited Tableau licenses.

1. On a site, click **Groups**, and then click **Add Group**.

Add new users by importing an Active Directory group. Type the name of the group you want to import, and then select the group name in the resulting list.

Import a Group from Active Directory

Import a group of users from Active Directory.

3. Click **Import**.

Note: Grant Site Role on Sign In can also be activated in local groups to provision minimum site roles to group members when they sign in to Tableau Server. For more information, see [Create a Local Group](#).

Modifying user roles with Grant role on sign in

If a user is part of a group using Grant role on sign in, then that user role can't be set to unlicensed or downgraded to a role lower than the minimum site role set for the group, whether or not they sign in. Administrators can upgrade a user's site role manually, however.

To downgrade a user's site role, or unlicense the user from the site, remove the user from the group(s) that have Grant role on sign in enabled.

In accordance with the terms of the [End User License Agreement](#), licenses granted on an Authorized User basis may be permanently reassigned to new users. Users may only be downgraded to a lower site role (including Unlicensed) when they will permanently discontinue access to Server Software at the higher role.

Removing users affected by Grant role on sign in

You can remove a user from a site only if the user does not own content. If you attempt to remove a user who owns content, the user site role will be set to Unlicensed and removed from all groups, but the user will not be removed from the site. To remove content owners, remove owners from group with Grant site role enabled or reassign content ownership to another user. For more information, see [Remove users from a site in the View, Manage, or Remove Users](#) help topic.

If the default All Users group has Grant site role enabled, users who own content can't be removed from the site or unlicensed. To remove or unlicense these users, reassign content ownership to another user, then remove or unlicense the user.

Tableau REST API can be used to reassign content ownership of a workbook. For more information, see [Update Workbook](#) method in the REST API Help. REST API can also be used to

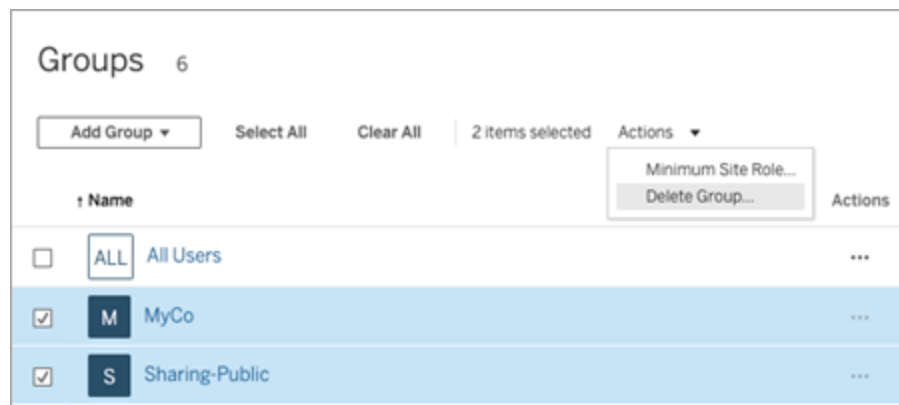

remove users from the site and transfer content ownership to another user. For more information, see [Remove User from Site](#) method in the REST API Help.

For more information on changing content ownership in Tableau Server, see [Manage Content Ownership](#).

Delete Groups

You can delete any group from the server with the exception of the **All Users** group. When you delete a group, the users are removed from the group but they are not deleted from the server.

1. Sign in to Tableau Server site as an administrator.
2. From the left navigation pane, click **Groups**.
3. On the Groups page, select one or more groups to delete.
4. Select **Actions > Delete**.

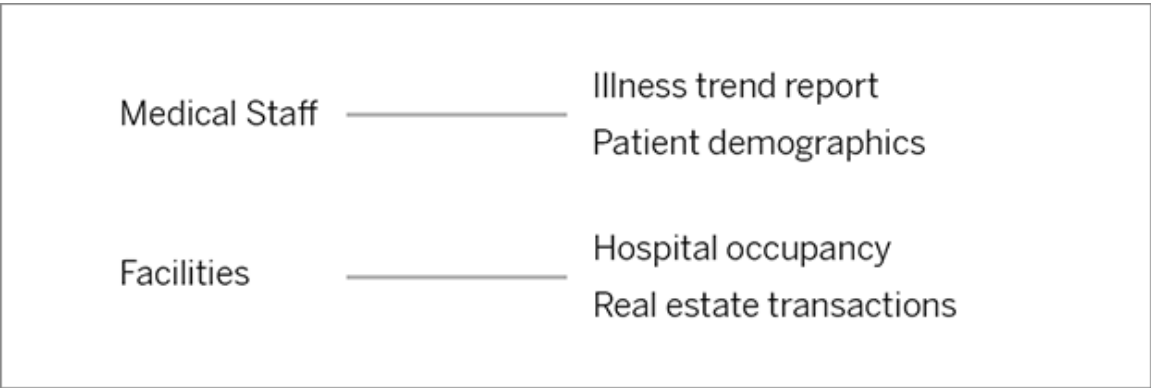

Dashboard-based Custom Portals

Note: This overview was inspired by the work of Tableau Visionary Mark Jackson. For more details about the process, [check out Mark's blog](#).

The **standard Tableau Cloud or Tableau Server interface** works great for many organizations, but if you want to create a company-branded experience and don't have API developer skills, consider creating a custom portal based on a Tableau dashboard. A custom portal lets you organize content around specific departments or job roles, and you can even incorporate training that helps people interact with data more fully. As the volume of Tableau content grows, a custom portal guides your users directly to the data they need, while providing ready access to related views and Tableau Server search so they can easily explore further.

Sketch out a portal design

Begin outside of Tableau, on paper or in a wireframing application. Consider the structure of your organization and the number of Tableau views that apply to each group of users. Do you simply need one level of navigation that points immediately to content? Or might you need to start with a main page that provides navigational links for separate groups of users or report types, followed by a second level with related dashboards and views?

After you get buy-in on your design from key stakeholders and data consumers, you're ready to move on to the next phase.

Gather images for logos and navigation elements

Start thinking about images while refining your initial mockup, and then gather them from libraries of clip-art or approved brand graphics, or create them from scratch in an application like

Photoshop or SnagIt. PowerPoint can also be a good source if you plan to create navigation thumbnails of common chart types.

Lay out text, images, and selected sheets on a dashboard

Create a workbook with a dashboard for the portal, using a [tiled layout](#) for more predictable positioning and scaling of elements on different devices. Then start adding Text and Image objects, as well as any sheets for data views you want to highlight right up front in your portal. To refine spacing between these dashboard elements, insert Blank objects and adjust their size. For more information, see [Create a Dashboard](#).

Tip: For dynamic elements that show popular or recently created content, include sheets based on [custom administrative views](#).

Link dashboard elements to content

If you have a second level of navigation in your portal, use [filter actions](#) to point to a secondary dashboard from the main one. To create links that directly open data views, right-click Image objects and choose Set URL. (In our example below, each colored arrow and accompanying text is an image that links to a view URL.) You can even point to empty views with preloaded data sources, encouraging users to create new Tableau content in the web-authoring workspace.

Tip: To add hyperlinks to text objects, include the full URL (for example, `http://www.tableau.com`).

Publish, test, and refine your portal

Publish the workbook to your server and distribute the dashboard URL to your users. Portal design, like data analysis itself, is a cyclical process. Now that your portal is out in the wild, start gathering user feedback so you can continuously improve the experience

Tip: As a finishing touch, hide the Tableau toolbar to give your portal a custom feel. After the question mark at the end of the dashboard URL, add `:embed=y&;:toolbar=n`

Manage Content Access

You can manage who can access content on your site and set the permissions that govern content ownership.

Set a Site's Web Authoring Access and Functions

Tableau Server administrators can specify at the site level whether to allow users to edit published views in the web environment and configure other web authoring functionality.

By default web authoring functionality is enabled for all sites. Users with the **Web Edit** capability can create and edit workbooks directly on the server. Turn off web authoring if you want users to be able to view and interact with published workbooks but not make any changes to the core information.

The steps below describe how to set web authoring and other associated functionality for an entire site. For more granular control over which users can use web editing, you can use projects, groups, and permissions. See [Set Web Edit, Save, and Download Access on Content](#).

For information about how to enable authoring for flows on the web, see [Create and Interact with Flows on the Web](#).

Turn web authoring on or off for a site

1. In a web browser, sign in to the server as an administrator and go to the site in which you want web authoring to be enabled. In that site, click **Settings**.
2. In the **Web Authoring** section, select **Workbooks. Let users edit workbooks in their browser.** to enable the functionality.

Clear the check box to turn off web authoring for that site.

Web Authoring

Users with the appropriate permissions can edit content in their browser.

- ☒ Workbooks. Let users edit workbooks in their browser.
- ☒ Flows. Let users edit flows in their browser.

3. If your site is already in production, and you want the change to take effect immediately, restart the server.

Otherwise, the change takes effect after server session caching expires or the next time users sign in after signing out.

Notes

- When you enable web authoring, make sure that, on the appropriate workbooks or views, the permission rule for a user or group allows the **Web Edit** capability.
- If you turn off web authoring on a production site and do not complete the last step to restart the server, users might continue to have authoring access until their session caches expire or they sign out.

See which sites allow web authoring

To confirm which sites allow web authoring, on the site-selection menu at the top, select **Manage All Sites**, and then go to the **Sites** page.

Sites 9										
<div><div>+ New Site</div><div>▼ 0 selected</div></div>										
	Name	Users	Site administrators	Max users	Storage used	Max storage	Status	Metrics	Web authoring

Configure cross-database join options

To improve performance for cross-database joins, users can allow Tableau to perform the join using the live database they are connected to instead of using Hyper. While this option is faster, if Tableau uses the connected database to perform the join, data from the file data source that the user is connected to is temporarily moved into temp tables in the database. Because this moves data outside of Tableau, as an administrator you may want to restrict access to this feature for users with web authoring permissions.

1. In a web browser, sign in to the server as an administrator and go to the site in which you want web authoring to be enabled. In that site, click **Settings**.
2. In the **Cross-Database Joins** setting, select one of the following options:
 - **Use Tableau or existing databases** - Select this option if you want to allow users to choose whether they want to allow Tableau to use the live database to perform cross database joins. Published data sources with this option enabled will continue to use the user's database for cross-database joins.
 - **Use Tableau only** - Select this option to restrict users to use only Hyper to perform cross data-base joins.

Cross-Database Joins

Choose where the join process happens when joining data from multiple sources. Allowing Tableau to use an existing database connection can be faster, but this means that data from the file connection may be temporarily moved to the live database connection. [Learn more](#)

☒ Use Tableau or existing databases
☐ Use Tableau only

If you select **Use Tableau only**, the option to choose how Tableau performs the cross-database join won't display in the canvas when the user connects to a supported data source and supported database. For more information about this feature, see [Improve performance for cross-database joins](#).

Set Web Edit, Save, and Download Access on Content

If you're enabling web authoring functionality on your site, you can configure more precisely which users on the site have access to this functionality. Using site roles and permissions rules at the content level, you can grant or deny **Web edit**, **Save**, or **Download** capabilities on projects, workbooks, and data sources.

Note: This document strives to use the phrase *Web edit* to specify the name of the capability in permissions rules, and *web authoring* to refer to the general functionality of creating and modifying workbooks on the server. However, you might otherwise see these two phrases used interchangeably.

Why allow users to work on the site directly

As an administrator, your initial thought about allowing people to populate a site with content, seemingly indiscriminately, might be one of skepticism. However, with a few controls, you can limit where this is done, while providing important benefits that centralized content management offers both you and your users.

Web authoring pros and cons

For publishers and business users, some benefits of web authoring include the following:

- It provides analyst teams who work collaboratively with a central location in which to provide input.
- It enables people who do not have Tableau Desktop to connect to data sources and create workbooks.
- It enables people to access content when they are away from their Tableau Desktop computer or VPN, whether on a computer or a hand-held device.
- It can provide a framework for enabling consistency across Tableau reports. (By making template workbooks available on the site, analysts can download or create new workbooks with data connections, branding, and formatting already in place.

For administrators, benefits can include the following:

- Fewer Tableau Desktop deployments to manage and support.
- Fewer computers that need to have database drivers installed.
- Capacity to govern content.
- More accurate monitoring of what people are doing with Tableau.

Some disadvantages to web editing include the following:

- For analysts, web editing functionality is not as extensive as in Tableau Desktop (although it continues to evolve toward that parity).
- For administrators, more people working on the server might mean upgrading systems.
- Without publishing guidelines, content proliferation on the site is expected. This can confuse the people who rely on published Tableau dashboards and data sources, degrade server performance and data quality, and potentially affect data security.

Managing permissions to help users avoid content proliferation

To help users to avoid content proliferation on the site, many Tableau administrators use projects to allow varying levels of access to content. For example, one project can be configured to allow all users to edit and save workbooks; another can allow only approved publishers to save new content.

To get a better idea how this works, see the following resources:

- [Configure Projects, Groups, and Permissions for Managed Self-Service](#)
 - [Governed Self-Service at Scale](#), a Tableau whitepaper by Rupali Jain.
- To view the PDF, you might need to provide your Tableau website credentials. These are the same ones you use for the community forums or to submit support cases.

Coordinate edit and save capabilities with site roles for the appropriate level of access

To edit, save, and download workbooks, users must have a site role that allows those actions, along with the capabilities—defined in permissions rules—that grant or deny editing-related access.

Site role access

- When the appropriate permissions are set at the content level, the **Creator** or **Explorer (can publish)** site role allows both **Save** (overwrite) and **Save As/Download**.

Note that **File > Save** is only available to the workbook owner. When the **Save** permission capability has been granted at the project and workbook level, a non-owner user can overwrite the existing workbook in web authoring by selecting **File > Save As** and using the same workbook name. This overwrites the existing content and they become the owner and gain full access to the content.

- The **Explorer** site role can be granted the **Web Edit** and **Save As/Download** capabilities, but they will not be able to save (neither overwriting existing nor saving changes to a new workbook).

For more information, see Web Editing and Web Authoring.

Configure Projects, Groups, and Permissions for Managed Self-Service

Publishing to Tableau Cloud and Tableau Server is easy. For some organizations, it might be a little *too* easy. There is value in creating a controlled framework before letting creators publish their own content.

To keep things tidy and to make sure people can find and access the right content, it may be useful to configure your site for managed self-service. This means having guidelines and settings in place to ensure content is organized, discoverable, and secure without having bottlenecks in the publishing process.

This article lays out a possible path for you as a site administrator to set up your site for managed self-service:

1. Identify the types of groups and projects you'll need
2. Create groups
3. Remove permissions that will cause ambiguities and establish default permission patterns

For more information on how Tableau permissions are evaluated, see [Effective permissions](#).

Identify the types of projects and groups you'll need

Designing a structure to accommodate content (in projects) and categories of users (as groups) can be the most challenging part of setting up a site, but it makes ongoing management much easier.

Projects: Projects function both as a unit for managing permissions and as an organizational and navigational framework. Try to create a project structure that balances how people expect to find content and allows for logical permissioning.

Groups: Before you create groups it can be useful to find common themes in how people interact with content. Try to identify patterns you can use to create groups and avoid one-off permissions for individual users.

Example: Project and group structure

For example, let's imagine an environment where there is company-wide content that everyone should be able to access, as well as some HR content that needs to be restricted.

Projects include:

- **Acme Corp Conference.** This will include data sources and workbooks for ticket sales, dashboards for content strategy, and project plans for the company conference.
- **Employee Success.** This will include anonymized data sources and workbooks for the internal employee survey
- **Human Resources.** This will include HR data sources and workbooks that should only be available to members of the HR team.

Then, groups should match what people need to do:

- **Core Content Creators.** This group is for users who can publish to top-level projects and have broad access to data sources, but who don't need to be able to move or

otherwise manage content.

- **HR Content Creators.** This group is for users who have access to HR data sources and can publish to the HR project.
- **Business Users.** This group is for users who should be able to access the content created by the Core Content Creators, but shouldn't even know the HR content exists.
- **HR Users.** This group is for users who should be able to access content in the HR project but don't have rights to create or publish content.
- **Core Project Leaders.** This group is for users who should be given project leader status on the projects that aren't HR.

Consider site roles

Remember that permissions are tied to content, not groups or users. This means that you can't give a group **Explore** permissions in a vacuum. Rather, the group can be given **Explore** permissions for a project and its content. Site roles, however, are given to specific users and may define or limit the permissions they can have. For more information on how licenses, site roles, and permissions tie together, see [Permissions, Site Roles, and Licenses](#).

Create the groups

While it might be tempting to create the groups and projects as soon as you identify what you need, it's important to do things in a certain order.

Projects: Projects shouldn't be created until after the Default project has been properly configured (see the next section). This is because top-level projects use the Default project as a template for their permission rules.

Groups: Groups need to be created before they can be used to build permission rules. Users do not need to be added to the groups yet, but they can be. For more information on creating groups, see [Manage Users Using Groups](#).

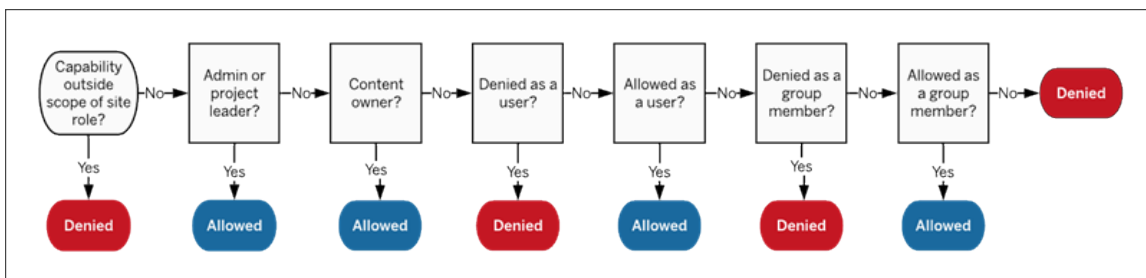

For more information on adding users to groups, see [Add Users to a Group](#).

Tip: Creating multiple groups and projects and setting permissions manually can get a little tedious. To automate these processes and make them repeatable for future updates, you can perform these tasks using **REST API** commands. You can use **tabcmd** commands for tasks such as adding or deleting a single project or group and adding users, but not for setting permissions.

Membership in multiple groups

It's possible to include the users in the HR Content Creators and HR Users groups in the Business Users group. This would make it easy to assign permissions to Core Content Users versus Business Users for the majority of content. However, in that scenario, the Business Users group couldn't be denied any capabilities in the Human Resources folder without denying the HR users as well. Instead, the Business Users group would have to be left as unspecified, and the specific HR Content Creators and HR Users groups would be given their applicable capabilities.

This is because Tableau permissions are restrictive. If the Business Users group was denied certain capabilities, that Deny would override the Allow of another permission rule for users in both groups.

When deciding how group membership should be assigned it's important to understand how permission rules are evaluated. For more information, see [Effective Permissions](#).

Remove permissions that will cause ambiguities and establish default permission patterns

Every site has an **All Users** group and a **Default** project .

All Users group: Any user added to the site becomes a member of the All Users group automatically. To avoid any confusion with permission rules set on multiple groups, it's best to remove the permissions from the All Users group.

Default project: The Default project works as a template for new projects in the site. All new top-level projects will take their permission rules from the Default project. Establishing baseline permission patterns on the Default project means you will have a predictable starting point for new projects. (Note that nested projects inherit the permission rules from their parent project, not the Default project.)

Remove the permission rule for the All Users group on the Default project

1. Select **Explore** to see the top-level projects on the site.
2. On the **Default** project's **Action (...)** menu, select **Permissions**.
3. Next to the **All Users** group name, select ..., and then select **Delete Rule....**

This lets you establish permission rules for the groups that you have full control over without any conflicting permissions assigned to All Users. For more information on how multiple rules are evaluated to determine effective permissions, see [Effective Permissions](#).

Create permission rules

Now you can set up the basic permission patterns for the Default project that all new top-level projects will inherit. You may choose to keep the Default project's permission rules empty and build permissions for each new top-level project individually. However, if there are any permission rules that should apply to the majority of projects, it can be helpful to set them on the Default project.

Remember that the permissions dialog for a project contains tabs for each type of content.

You must set permissions for each type of content at the project level or users will be denied access to that content type. (A capability is only granted to a user if they are expressly allowed it. Leaving a capability as Unspecified will result in it being denied. For more information, see [Effective Permissions](#).)

Tip: Every time you create a permission rule at the project level, make sure you look through all the content type tabs.

Create permission rules as desired:

1. Click **+ Add Group/User Rule** and start typing to search for a group name.
2. For each tab, choose an existing template from the drop-down or create a custom rule by clicking the capabilities.
3. When finished, click Save.

For more information on setting permissions, see [Set Permissions](#).

Example: Project level permissions for each content type

For our example, the majority of projects should be available to most people. For the default project, we'll use the [permission rules templates](#) to give the core content creators publishing rights and everyone else the ability to interact with workbooks and not much else.

Group	Projects	Workbooks	Data Sources	(Other content)
Core Content Creators	Publish	Publish	Publish	View
HR Content Creators	View	Explore	View	None
Business Users	View	Explore	View	None
HR Users	View	Explore	View	None
Core Project Leaders	Set as project leader	n/a	n/a	n/a

This pattern follows a closed model and limits permissions to basic usage for most content for most users. As new top-level projects are created, these rules are what will be inherited by default, but the permission rules can be modified per project as needed. Remember that the **Human Resources** project should have these permissions removed and its own pattern established.

Create projects and adjust permissions

After the Default project is set with your custom permissions templates, you can create the rest of your projects. For each project, you can adjust the default permissions as appropriate.

To create a project

1. Select **Explore** to see the top-level projects on the site.
2. From the **New** dropdown, select **Project**.
3. Name the project and, if desired, give it a description.

It can be useful to establish a naming convention. For example, a basic structure might be <DepartmentPrefix><Team> - <ContentUse>; such as DevOps - Monitoring.

The description appears when you hover over a project thumbnail and on the **Project details** page. A good description can help users know they're in the right place.

4. **Adjust permissions** as necessary.
 - a. Open the new project.
 - b. From the Action menu (...), select Permissions
 - c. Modify any permission rules as desired. *Remember to check all the content tabs.*

Lock content permissions

In addition to permission rules, projects have a content permission setting. This setting can be configured in two ways, either **Locked** (recommended) or **Customizable**.

Locking a project is a way of maintaining consistency and ensuring that all content in the project has uniform permissions (per content type). A customizable project permits authorized users set individual permission rules on pieces of content. For more information, see [Lock content permissions](#).

Regardless of the content permission setting, permissions are always enforced on content.

Possible project structures

Some organizations find it useful to have projects that serve specific purposes. Here are some example projects and their intended uses. Note that these are example templates and you should always test the configuration in your environment.

For information about what capabilities are included with each content type's permission rule templates, see [Permission capabilities](#).

Examples: permission settings for specific purposes

Workbooks shared for open collaboration on the server

Anyone in the department can publish to the open-collaboration project while their content is in development. Colleagues can collaborate using web editing on the server. Some people call this a sandbox, some call it staging, and so on. On this project you can allow web editing, saving, downloading, and so on.

Here you want not only to enable collaboration, but also to enable people who don't have Tableau Desktop to contribute and provide feedback.

Group	Projects	Workbooks	Data Sources	(Other content)
Data Stewards	Publish	Publish	Publish	TBD
Analysts	Publish	Publish	Explore	TBD

Business Users	Publish	Publish	Explore	<i>TBD</i>
-----------------------	---------	---------	---------	------------

Remember that some capabilities in the Publish template (such as Overwrite) may be **prevented by a user's site role** even if they are allowed that capability.

Note: "*TBD*" indicates these permission rules aren't easily determined by the scenario and can be set however makes sense for a given environment.

Shared reports that cannot be edited

This could be a project that people who create workbooks and data sources (Analysts and Data Stewards) could publish to when they want to make content available to business users for viewing, with confidence that their work cannot be “borrowed” or modified.

For this type of project, you would deny all capabilities that allow editing or getting the data off of the server for reuse. You would allow viewing capabilities.

Group	Projects	Workbooks	Data Sources	(Other content)
Data Stewards	Publish	<i>TBD</i>	Publish	<i>TBD</i>
Analysts	Publish	Publish	View	<i>TBD</i>
Business Users	View	View	None	None

Vetted data sources for Analysts to connect to

This would be where Data Stewards publish the data sources that meet all of your data requirements and become the “source of truth” for your organization. Project leaders on this project can certify these data sources, so that they rank higher in search results and are included in recommended data sources.

You would allow authorized Analysts to connect their workbooks to data sources in this project, but not download or edit them. You would deny the view capability to the Business Users group for this project, so those users would not even see this project.

Group	Projects	Workbooks	Data Sources	(Other content)
Data Stewards	Publish	<i>TBD</i>	Publish	<i>TBD</i>
Analysts	View	None	View	None
Business Users	None	None	None	None

Inactive content

Another possibility is to segregate workbooks and data sources that the site's administrative views show haven't been used for a period of time. You could give content owners a time limit before their content is removed from the server.

Whether you do this or delete directly from the working projects is up to your organization. In an active environment, don't be afraid to be intentional about removing content that is not being used.

Group	Projects	Workbooks	Data Sources	(Other content)
Data Stewards	None	None	None	None
Analysts	View	View	<i>TBD</i>	<i>TBD</i>
Business Users	None	None	None	None

Source for workbook templates

This is a project that people can download from but not publish or save to, where authorized publishers or project leaders make template workbooks available. Templates that have your

organization's approved fonts, colors, images, and even data connections built in can save authors a lot of time and keep your reports looking consistent.

Group	Projects	Workbooks	Data Sources	(Other content)
Authorized Author	Publish	Publish	Publish	<i>TBD</i>
Data Stewards	None	None	None	None
Analysts	View	<i>Template:</i> Explore + <i>Capability:</i> Download Workbook/Save a Copy	View	None
Business Users	None	None	None	None

Next steps

Besides projects, groups, and permissions, other data governance themes include:

User education

Help *all* of your Tableau users become good data stewards. The most successful Tableau organizations create Tableau user groups, have regular training sessions, and so on.

For a common approach to orienting users to the site, see [Dashboard-based Custom Portals](#).

For publishing and data certification tips, see the following topics:

- [Use Certification to Help Users Find Trusted Data](#)
- [Prepare for Publishing a Workbook](#) (links to Tableau Help)

- [Best Practices for Published Data Sources](#) (links to Tableau Help)

Optimize extract refresh and subscription activity

If you use Tableau Server, create policies for extract refresh and subscription schedules, to avoid them dominating the site's resources. The TC customer presentations by Wells Fargo and Sprint address this subject in detail. In addition, see the topics under [Performance Tuning](#).

If you use Tableau Cloud, see the following topics to become familiar with the ways people can refresh extracts:

- [Keep Data Fresh](#)
- [Use Tableau Bridge to Expand Data Freshness Options](#)

Monitoring

Use administrative views to keep an eye on the site's performance and content use.

[Administrative Views](#)

Use Projects to Manage Content Access

When Tableau Desktop users publish content to a site on Tableau Server, they can select a *project* to publish it to.

Projects can be used for navigation, organization, and access management for assets like workbooks, data sources, lenses, and nested projects. Starting in Tableau Cloud October 2022 / Server 2022.3, if Data Management is licensed and Catalog is enabled, a project can also contain external assets like databases.

The following image shows content within the top-level Operations project in the web authoring environment. The Operations project contains a few nested projects (highlighted) and published workbooks. A project can also contain other asset types.

Why use projects

Projects help you to create a scalable process for managing access to the content published to Tableau Server. Advantages they have include:

- They enable administrators to delegate content management to project leaders who work with the content more closely, without having to give them administrator access to site or server settings.
 - Project leaders can create nested projects under their top-level project, enabling them to maintain their team's content within a single hierarchy.
 - **Note:** Project owners can delete top-level projects they own. Project leaders cannot delete top-level projects.
- They can make the site easier to navigate for self-service users.
 - They segment the Tableau Server site into areas that give users access based on how they use the data published to those areas, or on the Tableau user group they work with.

- You can hide projects from groups who don't need to use them, create a distinguishable project-naming scheme, and take advantage of project descriptions to clarify how to use the project.
- They enable you to track permissions effectively.
 - You can create groups based on the level of content access users in the group need, and set default permissions on projects. This enables you to know exactly which capabilities new users get by default, and likewise which capabilities all users get when a new project is created.

When to create project hierarchies (example)

Many organizations have several or more distinct groups of Tableau users, each with its own priorities and leaders. These groups might share some organization-wide content (or even draw from an org-wide pool of data sources), but primarily they use data and reports that are specific to their team. In this or similar scenario, an example for using project hierarchies might look as follows:

1. You, as a site or server administrator, can create top-level projects for each of your distinct Tableau teams.
2. On each top-level project, you assign the Project Leader status to team leads, and change project ownership. Project leaders effectively are the content administrators, so it's important that they understand how permissions work in Tableau, along with Tableau content management best practices.
3. Each project leader can manage their project, creating the structure within the project that works for their team. That is, they can create child projects they need, based on how their team members collaborate and share data and reports.

The benefit to you as the site administrator is that you can focus on system health. The benefit to your Tableau users is that people who know the best practices for working with Tableau and data can manage these things for their teams, without having to submit IT requests to change permissions or add projects.

Why not use sites?

Sites work well when content can remain completely separate during all phases, and there is little to no user overlap. A good (and common) example for using multiple sites is to create a

site for each of multiple external clients, whose published content you manage as a consultant or vendor.

Projects allow the flexibility you need to administer shared data and reports, and users who might belong to multiple groups. Projects work better than sites for evolving content from development to staging to production.

Project-level administration

For more information about administering projects, see [Manage Permissions with Projects](#).

Add Projects and Move Content Into Them

Tableau content (such as workbooks, data sources, or metrics) must be in a project. Starting in Tableau Server 2022.3 and Tableau Cloud October 2022, if Data Management is licensed and Catalog is enabled, external assets (such as databases and tables) can also be in projects. Server and site administrators can add or remove top-level projects on a site, and move published content from one project to another. Project leaders with appropriate site roles can add or remove child projects and move content between projects on which they have Project Leader access.

This article contains the steps for creating and moving projects. We recommend becoming familiar with the following related content as well:

- To learn about projects and when or why to use them, see [Use Projects to Manage Content Access](#).
- Before you create project hierarchies, become familiar with [Permissions](#).
- To see the specific site roles that allow full Project Leader access, see [Project-level administration](#).

Add a top-level or child (nested) project

1. While you're signed in to Tableau Server as an administrator or project leader, select **Explore**, and then do one of the following:

- Select **New > Project** to create a new top-level project (only administrators can do this).
 - Navigate to and open the project in which you want to create a sub-project, and then select **New > Project**. If you're not sure where to find the child project, select **All Projects** from the drop-down menu next to **Explore**, or use the filters in the upper right.
2. Enter a name and description for the project, and then click **Create**.

New Project

Enter a name for the new project:

CS Training - open collaboration

Description

Use this project to fine tune your analysis with your CS colleagues.

3,932 characters remaining

> Show formatting hints

Cancel Create

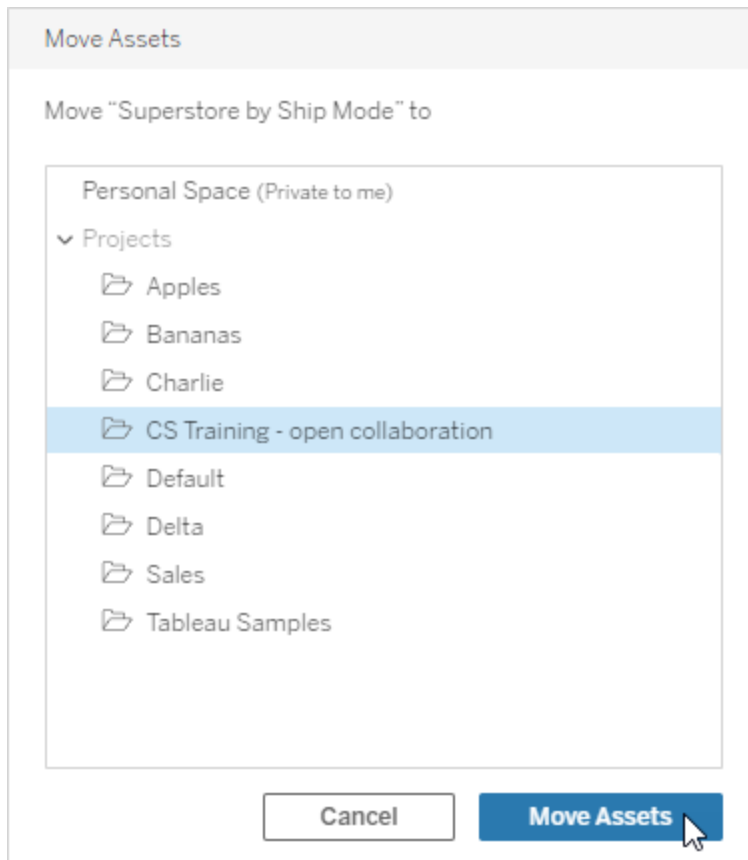

You can include formatting and hyperlinks in the project description. Select **Show formatting hints** for syntax.

When entering a project description, include a space between capital letters and parentheses to display content inside them, such as "PROJECT (a)". Omitting this space will cause display issues in the project description.

Note: To edit a project description later, select it to open it, select the information icon next to its name, and then click **Edit**.

Move an asset to another project

1. In the **Explore** section, find the asset you want to move. You can use the filters in the upper right to search, or you can navigate through the project hierarchy.
2. On the workbook's **Actions(...)** menu, select **Move**.
3. Select the new project for the workbook, and then click **Move Content**.

Moving a project includes moving everything in it, including child projects and their assets.

How moving projects affect permissions

When you move a project, Project Leader permissions adapt to the new project environment.

- When the target project hierarchy is **Locked**, previous Project Leader permissions are removed, and new Project Leader permissions are granted according to those set at the top-level of the target hierarchy.
- When the target project hierarchy is **Customizable**, previous implicitly granted Project Leader permissions are removed, explicitly set Project Leader permissions are retained, and new Project Leader permissions are granted according to those set at the top-level of the target hierarchy.

When you move a project and assets, permissions may be impacted. For more information, see [Permissions](#).

Delete a project

When you delete a project, all of the Tableau content in the project is also deleted. If you want to delete a project but not its content, move the content to another project, and then delete the project.

External assets, such as databases and tables, are not deleted, but are moved to the **External Assets Default Project**. (In Tableau Server 2022.3 and earlier, the assets can be found in **External Assets**.)

Important

- You cannot undo deleting a project.
- Deleting a project deletes all Tableau content in it, including child projects and their content, but not external assets.
- You cannot delete the **Default** project or the **External Assets Default Project**.

To delete a project:

1. In the **Explore** section, find the project you want to remove. If you're not sure where to find the project, select **All Projects** from the drop-down menu next to **Explore**, or use the filters in the upper right.
2. On the project's **Actions (...)** menu, select **Delete**.
3. Confirm that you want to delete the project.

Requirements for moving assets

Moving an asset is effectively like removing it from one project and publishing it to another. For non-administrators, the permissions needed on the source project are different from those needed on the destination project.

Required site role

To move assets, users must have one of the following site roles:

- Server Administrator (Tableau Server only)
- Site Administrator Creator or Site Administrator Explorer
- Creator or Explorer (can publish)

Users with a Server Administrator or Site Administrator site role do not need any additional capabilities.

Required permissions for the project that users move content *to*

Non-administrators must have the **Publish** permission capability for the destination project.

Required permissions for the project that users move content *from*

Non-administrator users must

- Be the project owner, project leader, or content owner for the original project

OR

- Have the **Move** permission capability for the content (or, for data sources, be the data source owner). When moving a database with its tables, the user must have the Move capability for both the database *and* its tables.

For more information on moving assets, see [Move content](#).

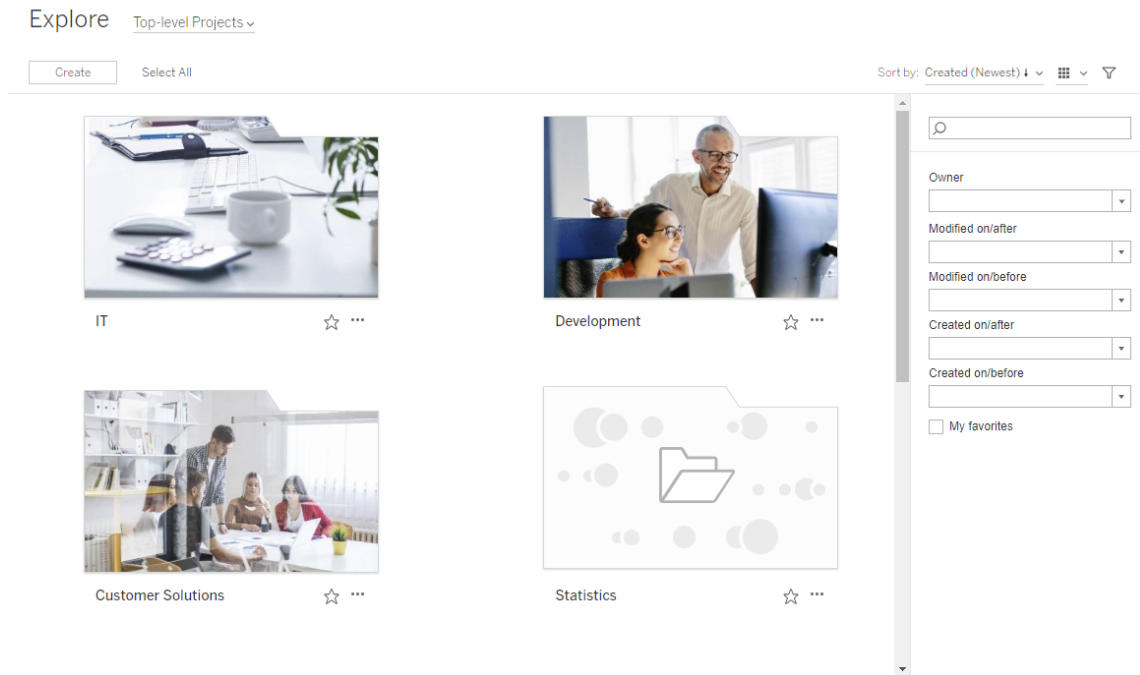

Add a Project Image

To help distinguish projects you manage on Tableau Server (and help your users find them), you can add an image that appears in the thumbnail. Your image must meet the following requirements:

- The image must be accessible using HTTPS protocol. Shared network directory and related protocols (UNC, SMB, AFP, NFS, etc) are not supported. HTTP protocol for

project images is not supported by Google Chrome.

- All users who access the project must have, at a minimum, "read-only" permission on the target image.
- The image must be common internet format: .jpg, png, or gif.

Set a project image

1. Sign in to a site on Tableau Server. In the list of **Top-level Projects** you have access to, select or navigate to the project you want to update. In this example, we'll add an image to the Statistics project folder.

If you're not sure where to find a child project, use the **Explore** drop-down list and select **All Projects**.

2. Click the **Details** icon (i), to open the **Project details** dialog box, and then click **Edit**.

3. In the **About** field, you can enter a description for your project (optional), for example "Global and US statistics." At the end of the project description, add the URL for your image using the following syntax:

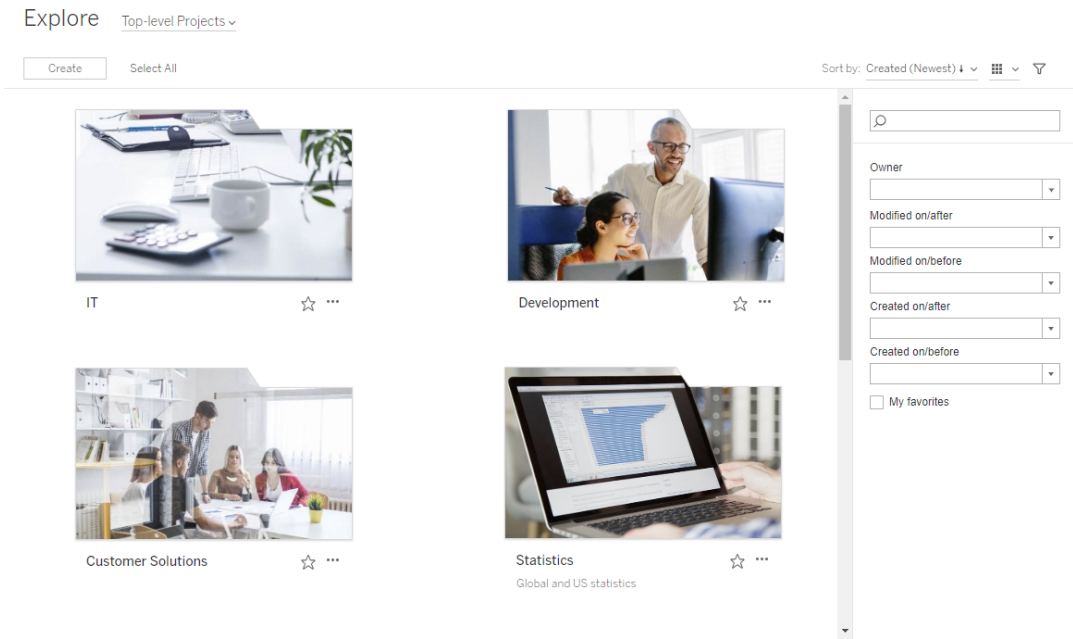

`!http://www.example.com/image.png!`

Select **Show formatting hints** to see how you can format description text.

Note: Images embedded in project descriptions cannot be resized or positioned. Recommended size is (300 x 184 pixels). Images that are not 300 x 184 pixels may be stretched, shrunk, or cropped to fit the width of the thumbnail. In addition, they must be added at the end of the project description and be enclosed in ! (exclamation marks), otherwise they will not be displayed as the thumbnail.

4. Click **Save**.

Let Site Users Request Access to Content

Permissions determine if a user has viewing access to a workbook, view, or other content inside a project. If a user clicks on content or a project they don't have access to, they can send a request for access to the owner who controls permissions for that content.

Permission Required

You don't have access to this workbook. Send a request for access.

Message (optional)

0 / 500

Cancel

Request Access

When someone requests access, the owner who controls permissions for that content (either at the project or workbook level) receives an email with the name and email of the requester, the content or project requested, and a link to grant access to the content. In Tableau Server version 2022.3 and earlier, the owner receives a link to the content to manage permissions instead of a link to directly grant access.

1. On the email notification, select **Grant Access**.
2. On the dialog that appears, to grant the view permissions template, select **Grant Access**. To grant permissions other than the view template, select **Manage Permissions**.

If a user requests access to a workbook and content permissions are locked to the project, then the project owner receives the request. Likewise, if a user requests access to a workbook and project permissions are managed by the workbook owner, then the workbook owner receives the request.

After permission is granted, the owner can email the requester to let them know they have view capability to the project or workbook.

Default settings

The Request Access setting is enabled by default on a new site. To enable the setting if it's been disabled:

1. Go to the General tab of the Settings page for your site.
 - If you have a single site, on the side navigation, click **Settings** and **General**.
 - If you have multiple sites, select the site you want to configure and click **Settings** and **General**.
2. On the General tab, scroll down to Request Access and select **Let users request access to projects, workbooks, and views**.
3. Click **Save**.

Configure project permissions

You can control who receives the access request by adjusting the project's content permissions. If content permissions are:

- Locked to the project: the project owner receives the request.
- Managed by the owner: The workbook owner receives the request.

To manage content access using projects, see [Use Projects to Manage Content Access and Permissions](#).

For more information about how permission rules are evaluated, see [Permissions: Evaluate permission rules](#).

Change project permissions

For administrators and project leaders

Permissions can be set at the project level for both the project itself and for any content in the project. For example, if workbook permissions are configured at the project level, all workbooks published into that project inherit those default permissions. However, the Creator can choose to change the permissions during publishing, or certain users can change the permissions on published content. To enforce the permissions established at the project level, **Content Permissions** can be locked to the project. For more information, see [Lock asset permissions](#).

To set permissions at the project level:

1. Navigate to the project
2. Open the Actions menu (...) and click **Permissions**. The permissions dialog box opens.

This dialog box has two main areas: permission rules at the top and the effective permissions grid below. Use the tabs to navigate between types of content.

Permissions for Project "My Project"

Content permissions: Locked including nested projects [Edit](#)

Permission Rules

			Projects	Workbooks	Data Sources	Data Roles	Flows	Metrics
Group/User		Template						
All Users	...	View	✓	✓	✓	✓	✓	✓
Group	...	Explore	✓	✓	✓	✓	✓	✓
Evie	...	Publish	✓	✓	✓	✓	✓	✓
Lari	...	Administer	✓	✓	✓	✓	✓	✓
Maris	...	Custom	✓	✓	✓	✗	✗	✗

+ Add Group/User Rule

Effective Permissions

Search for a user to view their effective permissions

User	Site Role								
Lari	Site Administrat...	✓	✓	✓	✓	✓	✓	✓	✓
Maris	Explorer (can pu...	✓	✓	✓	✓	✗	✗	✗	✗
Will	Unlicensed	✓	✗	✗	✗	✗	✗	✗	✗

Download Summary Data: Denied (by user rule)

With a row selected at the top, the effective permissions grid populates. Use this to verify permissions. Hovering over a capability indicator provides information about why the capability is allowed or denied for that specific user.

- To modify an existing permission rule, select the rule and click the capability boxes to toggle through allowed/denied/unspecified.
- To create a new rule,
 - Select **+ Add Group/User Rule**.
 - Select a group or user from the drop-down box. This creates a row where you can configure the permission rule.
- In the row for the permission rule
 - choose an existing permission role template from the drop-down box for each content type tab.

- b. Or create a custom rule by navigating to a content type tab and clicking the capabilities. One click sets the capability to **Allowed**, two clicks sets it to **Denied**, and a third click clears the selection (**Unspecified**).
6. When finished, click **Save**.

Change content permissions

For administrators, project leaders, and content owners

If project permissions are not locked, permissions for individual pieces of content can be modified.

Warning: Tableau recommends managing permissions at the project level within the Tableau site. These steps are relevant only for content in projects where permissions are managed by the owner.

Set permissions on content

1. Navigate to the content (workbook, data source, flow, data role)
2. Open the Actions menu (...) and click **Permissions**. The permissions dialog box opens.

This dialog box has two main areas: permission rules at the top and the effective permissions grid below.

Search for a user to view their permissions Permissions for views are controlled independently

User / Group	Permissions	View	Interact/Edit	Edit
	Managed by the owner			
All Users (39) ...	None			
Site Roles (8) ...	Editor			

[+ Add a user or group rule](#)

User Permissions	Site Roles (8)
Creator	Editor
Explorer	Custom
Explorer (can publish)	Editor
Server Administrator	Administrator
Site Administrator Creator	Administrator
Site Administrator Explorer	Administrator
Unlicensed	Custom
Viewer	Custom

Save: Denied (by user's site role)

With a row selected at the top, the effective permissions grid populates. Use this to verify permissions. Hovering over a capability square provides information about why the capability is allowed or denied for that specific user.

- To modify an existing permission rule, open the Actions menu (...) for that row and click **Edit**.
- To create a new rule,
 - Select **+ Add a user or group rule**.
 - If necessary, use the drop-down box on the right to change between groups and users.
 - Select a group or user from the drop-down box. This creates a row where you can configure the permission rule.
- In the row for the permission rule, choose an existing permissions role template from the drop-down box or create a custom rule by clicking the capabilities.

One click sets the capability to **Allowed**, two clicks sets it to **Denied**, and a third click clears the selection (**Unspecified**).

- When finished, click **Save**.

Set permissions on a view

In some situations, it may be valuable to specify permissions on a view independently from the workbook that contains it. To set permissions on a published view, navigate to the view within a published workbook and follow steps above.

Warning: While it is possible to set view-level permissions within a workbook, we strongly recommend managing permissions at the project (or workbook) level as much as possible. For views to inherit permissions, the project must be locked or the workbook must be published with **Show Sheets as Tabs**. See [Let Site Users Request Access to Content](#) for more information.

Permissions

Permissions determine how users can interact with content such as workbooks and data sources. Permissions are set in the permission dialog or via the [REST API](#). At the top of the dialog, permission rules configure capabilities for groups or users. Below, the permissions grid displays the effective permissions for users.

Permissions for Project "My Project"

Download Summary Data: Denied (by user rule)

There are several interrelated topics that discuss how to think about, set, and manage permissions. The main topics are:

- This topic, which covers the fundamentals, how to set permission rules for projects and other content, and permission considerations for specific scenarios.
- Permission Capabilities and Templates, which covers in detail the various capabilities that are used to build permission rules.
- Manage Permissions with Projects, which covers using projects to manage permissions and how nested and locked projects impact permissions.
- Effective permissions, which covers how permission rules are evaluated and how final permissions are determined.
- Permissions, Site Roles, and Licenses, which covers how permissions interact with site roles and licenses to determine what a user can do on a site.

Additionally, if Data Management is licensed, permissions for external assets have additional considerations. For more information, see [Manage Permissions for External Assets](#).

Permissions fundamentals

Projects and groups

Tableau sites use *projects* to organize content and *groups* to organize users. Managing permissions is easier when permission rules are:

- Set at the project level instead of on individual pieces of content.
- Established for groups instead of individuals.

Permissions can only be established for users, groups, projects, or assets that already exist. For more information about creating users and groups, creating projects, and publishing content, see [Manage Users and Groups](#), [Use Projects to Manage Content Access](#), and [Publish Data Sources and Workbooks](#).

Capabilities and permission rules

Permissions are made up of *capabilities*—the ability to perform actions like view content, web edit, download data sources, or delete content. *Permission rules* establish what capabilities are allowed or denied for a user or group on an asset.

For more information about capabilities and permission rule templates, see [Permission Capabilities and Templates](#).

Note: When talking about permissions in general, it's common to see a phrase like "a user must have the delete *permission*." This is easy to understand in a broad context. However, when working with permissions at a technical level like in this article, it's more accurate to say "the delete *capability*." In this topic we'll use the more precise term *capability*, but you should be aware that you might see *permission* in other places.

The interplay between license level, site role, and potentially multiple permission rules factor into the final determination of what a user can or can't do. For each user this becomes their *effective permissions*. For more information, see [Effective permissions](#). Some tasks such as creating new workbooks from a browser (web authoring) or moving content might require specific configurations of several capabilities rather than being captured in a single capability. For more information, see [Permission settings for specific scenarios](#).

Permission rules are set differently at the project level, at the content level, or when publishing content from Tableau Desktop.

For administrators, project owners, and project leaders

To set permissions at the project level:

1. Navigate to the project
2. Open the Actions menu (...) and click **Permissions**.

The permissions dialog opens. This dialog has two main areas: permission rules at the top and the effective permissions grid below. Each content type has a tab. The image below shows the Workbook tab.

Permissions for Project "My Project"

Content permissions: Locked including nested projects [Edit](#)

Permission Rules

			Projects	Workbooks	Data Sources	Data Roles	Flows	Metrics
Group/User		Template						
All Users	...	View	✓	✓	✓	✓	✓	✓
Group	...	Explore	✓	✓	✓	✓	✓	✓
Evie	...	Publish	✓	✓	✓	✓	✓	✓
Lari	...	Administer	✓	✓	✓	✓	✓	✓
Maris	...	Custom	✓	✓	✓	✗	✗	✗

+ Add Group/User Rule

Effective Permissions

Search for a user to view their effective permissions

User	Site Role							
Lari	Site Administrat...	✓	✓	✓	✓	✓	✓	✓
Maris	Explorer (can pu...	✓	✓	✓	✗	✗	✗	✗
Will	Unlicensed	✓	✗	✗	✗	✗	✗	✗

Download Summary Data: Denied (by user rule)

With a row selected at the top, the effective permissions grid populates. Use this to verify permissions. Hovering provides information about why the capability is allowed or denied for that specific user.

- 3. To modify an existing permission rule, select the appropriate tab for that content type and click a capability.
- 4. To create a rule, click **+ Add Group/User Rule** and start typing to search for a group or user. For each tab, choose an existing template from the dropdown box or create a custom rule by clicking the capabilities.

One click sets the capability to **Allowed**, two clicks sets it to **Denied**, and a third click clears the selection (**Unspecified**).

- 5. When finished, click **Save**.
 - If the "None" template is selected, the button will say "Delete Rule".

Set project permissions for all content types

Remember that the permissions dialog for a project contains tabs for each type of content.

You must set permissions for each type of content at the project level or users will be denied access to that content type. A capability is only granted to a user if they're expressly allowed it. Leaving a capability as Unspecified will result in it being denied.

Tip: Every time you create a permission rule at the project level, make sure you look through all the content type tabs.

Configure the asset permissions setting

Permission rules set at the project level act as a default for content saved in that project and any nested projects it contains. Whether those project-level default rules are kept uniform or are able to be edited depends on the **Asset permissions** setting. This setting can be configured in two ways, either **Locked** or **Customizable**. For more information, see Lock asset permissions.

Content-level permissions

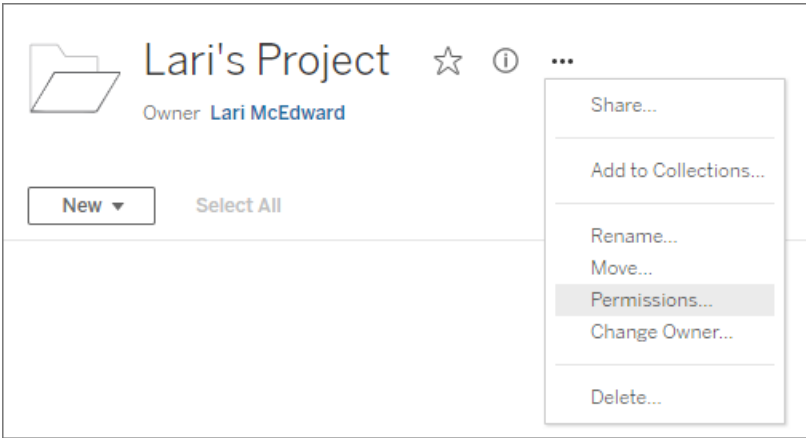

For administrators, project leaders, and content owners

If project **Asset permissions** are **Customizable**, permissions for individual assets can be modified. The information below isn't relevant to assets in locked projects. For more information, see Lock asset permissions.

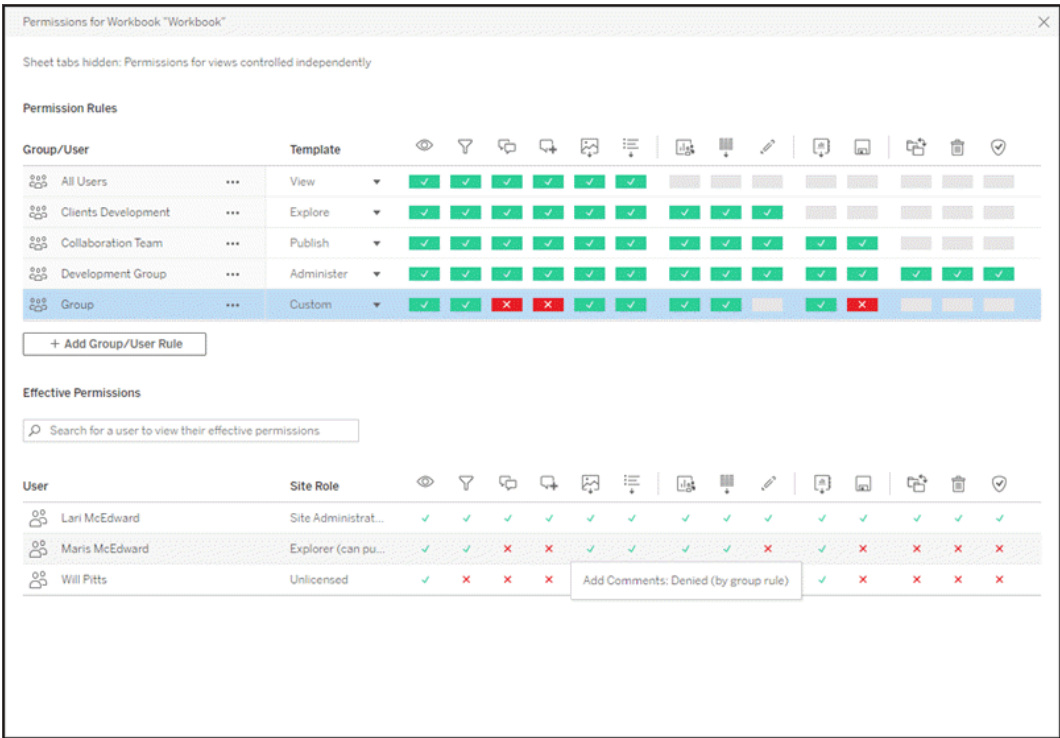

Tip: While it is possible to set permissions on individual assets in **Customizable** projects, we recommend managing permissions at the project level.

Set permissions on assets

1. Navigate to the asset (such as a workbook, data source, or flow)
2. Open the Actions menu (...) and click **Permissions**.

The permissions dialog opens. This dialog has two main areas: permission rules at the top and the effective permissions grid below. (Note the lack of tabs across the top—an asset-level permissions dialog has no tabs.)

With a row selected at the top, the effective permissions grid populates. Use this to verify permissions. Hovering over a capability square provides information about why the capability is allowed or denied for that specific user.

3. To modify an existing permission rule, click a capability.
4. To create a rule, click **+ Add Group/User Rule** and start typing to search for a group or user. Choose an existing template from the dropdown or create a custom rule by clicking the capabilities.

One click sets the capability to **Allowed**, two clicks sets it to **Denied**, and a third click clears the selection (**Unspecified**).

5. When finished, click **Save**.
 - If the "None" template is selected, the button will say "Delete Rule".

Set permissions on a view

Tip: While it's possible to set view-level permissions within a workbook, we strongly recommend managing permissions at the project (or, if necessary, workbook) level.

If a workbook is published with **Show Sheets as Tabs** checked, the views in that workbook will inherit all permissions set for the workbook. The permission dialog for a view will be read-only.

In some situations, it may be valuable to specify permissions on a view independently from the workbook that contains it. If the workbook is published with **Show Sheets as Tabs** unchecked (sheet tabs hidden), the views will start with the workbook permissions but will be independent thereafter and can be set independently. Note that this means if the permission rules are modified for the workbook, those changes won't be applied to the views—each view's permissions will need to be managed individually.

See [Show or Hide Sheet Tabs](#) for more information.

Set permissions at publish

For content publishers

If project **Asset permissions** are **Customizable**, permissions for individual assets can be set when publishing from Tableau Desktop. The information below isn't relevant for content in locked projects. For more information, see Lock asset permissions.

Tip: While it's possible to set permissions on individual assets in **Customizable** projects, we recommend managing permissions at the project level.

1. From the publishing dialog, click the Edit link for **Permissions**.
If the Edit link is unavailable, permissions are locked to the project and can't be modified except by the project owner, project leader, or an administrator.
2. The Add/Edit Permissions dialog shows any existing permission rules. Click **Add** to add a permission rule or **Edit** to modify an existing permission rule
 - a. Select the group or user from the left pane. You can expand a group to see which users it contains.
 - b. Use the selector at the top of the right pane to choose an existing template, or use the radio buttons to create a custom rule.

	Allow	Deny	Unspecified
View:	<input checked="" type="radio"/>	<input type="radio"/>	<input type="radio"/>
Filter:	<input checked="" type="radio"/>	<input type="radio"/>	<input type="radio"/>
View Comments:	<input checked="" type="radio"/>	<input type="radio"/>	<input type="radio"/>
Add Comments:	<input checked="" type="radio"/>	<input type="radio"/>	<input type="radio"/>
Download Image/PDF:	<input checked="" type="radio"/>	<input type="radio"/>	<input type="radio"/>
Download Summary Data:	<input checked="" type="radio"/>	<input type="radio"/>	<input type="radio"/>
Share Customized:	<input checked="" type="radio"/>	<input type="radio"/>	<input type="radio"/>
Download Full Data:	<input checked="" type="radio"/>	<input type="radio"/>	<input type="radio"/>
Web Edit:	<input checked="" type="radio"/>	<input type="radio"/>	<input type="radio"/>
Download/Save A Copy:	<input type="radio"/>	<input type="radio"/>	<input checked="" type="radio"/>
Overwrite:	<input type="radio"/>	<input type="radio"/>	<input checked="" type="radio"/>
Move:	<input type="radio"/>	<input type="radio"/>	<input checked="" type="radio"/>
Delete:	<input type="radio"/>	<input type="radio"/>	<input checked="" type="radio"/>
Set Permissions:	<input type="radio"/>	<input type="radio"/>	<input checked="" type="radio"/>

Note that effective permissions can't be inspected from the publishing dialog.

3. When finished, click **OK** and resume publishing.

Note: Permissions can't be set while publishing flows from Tableau Prep Builder. To set permissions on a flow, refer to the steps for Project-level permissions or Content-level permissions.

Clean up the All Users group

By default, all users are added to an "All Users" group that has basic permissions for content. To start with a clean slate when building your own permission rules, we recommend that you delete the rule entirely or edit the rule for All Users to remove any permissions (set the permission role template to None). This helps prevent any ambiguity down the road by reducing the number of rules that applies to any given user and therefore making effective permissions easier to understand.

Permission settings for specific scenarios

Certain actions require combinations of permission capabilities and possibly site roles. The following are some common scenarios and their necessary permission configurations

Saving, publishing, and overwriting

In the context of permissions, saving is essentially publishing. As such, the **Overwrite** and **Save a Copy** capabilities can only be given to users with a site role that allows publishing: Administrator, Creator, or Explorer (can publish). Explorer or Viewer site roles can't publish, overwrite, or save a copy.

- The **Publish** capability for a project allows a user to publish content into that project.
- The **Overwrite** capability allows a user to save over an existing piece of content. By saving over the content, the user becomes the owner of that content. The Overwrite capability also allows users to edit minor aspects of existing pieces of content, such as the description for a metric or the synonyms for a data role. Editing the existing content in this way doesn't change the owner of the content.

- The **Save a Copy** capability allows a user to save a new copy of the content. This is usually done in conjunction with web authoring and means the user can save their modifications.

It's important to note that users aren't able to Save or Save As a piece of content unless they've the **Publish** capability for at least one project, because all content must be published into a project. Without the **Publish** capability at the project level, the content can't be published.

In web editing, the **Save** option in the File menu only appears to the content owner. If a user who isn't the owner has the **Overwrite** capability (allowing them to save the content), they must use **File > Save As** and name the workbook the exact same name. This prompts a warning that they're about to overwrite the existing content, which they can do. Conversely, a user with only the **Save a Copy** capability trying to use the same name gets an error stating they don't have permission to overwrite the existing content.

If a user who isn't the content owner overwrites content, they become the owner, with all the permissions that entails. The original owner's access to the content is then determined by their permissions as a user rather than the owner.

Note: **Download Workbook/Save a Copy** is a joint capability for workbooks. Explorers can be given this capability but they're only able to download the workbook, not save a copy. Giving the capability to Explorer (can publish), Creator, or Administrator site roles gives them both the ability to download workbooks *and* save a copy.

Web Editing and Web Authoring

Web editing and web authoring allows users to edit or create workbooks directly in the browser.

The permission capability is called *Web Edit* and the site setting is called *Web Authoring*. This section refers to any web-based editing or publishing action as *web authoring*.

To enable this functionality, there are several requirements.

- **Site setting:** Web authoring must be turned on for the entire Tableau site. See [Set a Site's Web Authoring Access](#). Without this setting enabled, no users can create workbooks or edit existing workbooks from the browser, *even if they have the web edit capability*.
- **User site role:** The user must have the appropriate site role.
 - Viewers can never web edit.
 - Explorers can be given the web edit capability but can't publish. Essentially, they can use web editing to answer deeper questions based on existing content on the fly, but can't save their edits.
 - Explorers (can publish) or Site Administrator Explorers can publish, but they can only use data that is already published to the site.
 - Creators, Site Administrator Creators, and Server Administrators can publish and create data sources.
- **Permission capabilities:** The user must have the necessary permission capabilities based on the desired functionality.

Required Permission Capability Settings

Desired functionality	Minimum Site Role	 Web Edit	 Download/ Save a Copy	 Overwrite (workbook)	 Publish (project)	 Connect (data source)
Web author without being able to save	<i>Explorer</i>	 Allow	 Deny	 Deny	Optional	 Allow
Web author and save as new content	<i>Explorer (can publish)</i>	 Allow	 Allow	 Deny	 Allow	 Allow
Web author and save (overwrite) content	<i>Explorer (can publish)</i>	 Allow	 Allow	 Allow	 Allow	 Allow

Web author with new data and save new content	<i>Creator</i>		Optional	Optional		Optional
		Allow			Allow	

Optional indicates this capability isn't involved in the desired functionality

Data access for published Tableau data sources

Data sources published to a Tableau site can have native authentication as well as permissions within the Tableau environment.

When the data source is published to the Tableau site, the publisher can choose how to [Set Credentials for Accessing Your Published Data](#), which addresses how data source credentials are handled (such as requiring users to log into a database or enter their credentials for Google Sheets). This authentication is controlled by whatever technology holds the data. This can be embedded when the data source is published, or the data source publisher can choose to prompt the user for their credentials to the data source. For more information, see [Publish a Data Source](#).

There are also data source capabilities that allow or deny users the ability to see (**View**) and connect to the published data source (**Connect**) in the context of Tableau. These capabilities are set like any other permissions in Tableau.

When a workbook is published that uses a published data source, the author can control how the Tableau authentication behaves for someone consuming the workbook. The author sets the workbook's access to the published data source, either as **Embed password** (using the author's Connect access to the data source) or **Prompt users** (using the Connect access of the person viewing the workbook), which may require data source authentication as well.

- When the workbook is set to **Embed password**, anyone who looks at the workbook sees the data based on the author's access to the data source.
- If the workbook is set to **Prompt users**, the Tableau-controlled access is checked for the data source. The person consuming the workbook must have the Connect cap-

ability for the published data source to see the data. If the published data source is also set to Prompt user, the viewer must also enter their credentials for the data source itself.

Workbook authentication to the data source	Data source authentication to the data	How data access is evaluated for someone consuming the workbook
Embed password	Embed password	User sees the data as if they were the workbook author
Embed password	Prompt user	User sees the data as if they were the workbook author. (The author is prompted for data source authentication, not the user.)
Prompt user	Embed password	User must have their own Connect capability to the published data source
Prompt user	Prompt user	User must have their own Connect capability to the published data source and are prompted for their credentials to the underlying data

Note that this applies to consuming a workbook, not web editing. To web edit, the user must have their own Connect capability.

For information on embedding passwords when you publish Tableau content such as a data source or workbook that uses a virtual connection, see [Virtual connections](#) in the Tableau Server help.

Move content

To move an item, open its Action menu (...) and click **Move**. Select the new project for the item, then click **Move Assets**. If **Move** is unavailable or there are no available destination projects, verify the appropriate conditions are met:

- Administrators can always move assets and projects to any location.
- Project leaders and project owners can move assets and nested projects among their projects.
 - Note that non-administrators can't move projects to become top-level projects

- Other users can move assets only if all three of the following requirements are met:
 - Creator or Explorer (Can Publish) site role.
 - Publishing rights (**View** and **Publish** capabilities) for the destination project
 - Owner of the content, or—for workbooks and flows—having the **Move** capability.

When moving a database with its tables, the user must have the **Move** capability for both the database *and* its tables.

For information about how permissions are handled when moving content and projects, see [Move projects and content](#).

Metrics

Metrics are created from views in published workbooks. Users can create metrics if they:

- Are a Creator or Explorer (can publish) site role
- Have the **Publish** capability on a project
- Have the **Create/Refresh Metric** capability for the relevant workbook

For more information, see [Create and Troubleshoot Metrics](#) and [Set Up for Metrics](#).

Note: Prior to 2021.3, the ability to create a metric on a view was controlled by the Download Full Data capability.

Because metrics are independent assets, it's important to note that the permissions for metrics are managed independently from the view they were created from. (This is unlike data-driven alerts and subscriptions, where the content of the alert or subscription can only be seen if the user has the correct permissions for the view itself.)

Although the capabilities for metrics are straightforward, the **View** capability should be considered carefully. It may be possible for a workbook with restricted permissions to be the basis for a metric with more open permissions. To protect sensitive data, you might want to deny metric creation for specific workbooks.

Metrics display data from their owner's perspective

When you create a metric, you capture your perspective of the data from that view. This means that any users who can access your metric will see the data as it appears to you. If the data in the view is filtered based on your credentials, the data you see might be different from what other users see when they access the same view. Limit the **View** capability for your metric if you're concerned about exposing your perspective of the data.

Explain Data

When Explain Data is available, a user can select a mark in a view and click Run Explain Data in the mark's Tooltip menu. A combination of settings must be enabled to make Explain Data available in editing mode and viewing mode.

Requirements for authors to run Explain Data or edit Explain Data settings in editing mode:

- Site setting: **Availability of Explain Data** set to **Enable**. Enabled by default.
- Site role: Creator, Explorer (can publish)
- Permissions: **Run Explain Data** capability set to **Allowed**. Unspecified by default. If you open a workbook (Tableau version 2022.1 or earlier) that used this permission in Tableau version 2022.2 or later, you must reset the Run Explain Data capability to Allowed.

Note: The **Download Full Data** capability for a Creator or Explorer (can publish) controls whether they see the View Full Data option in Extreme Values explanations. Viewers are always denied the Download Full Data capability. However, all users can see record-level details when the Extreme Values explanation type is enabled in Explain Data settings.

Requirements for all users to run Explain Data in viewing mode:

- Site setting: **Availability of Explain Data** set to **Enable**. Enabled by default.
- Site role: Creator, Explorer, or Viewer
- Permissions: **Run Explain Data** capability set to **Allowed**. Unspecified by default. If you open a workbook (Tableau version 2022.1 or earlier) that used this permission in Tableau version 2022.2 or later, you'll need to reset the Run Explain Data capability to Allowed.

Show or Hide Sheet Tabs

In the context of published content, sheet tabs (also referred to as tabbed views) is a distinct concept from sheet tabs in Tableau Desktop. Showing and hiding sheet tabs in Tableau Desktop refers to hiding sheets in the authoring environment. For more information, see [Manage Sheets in Dashboards and Stories](#).

Showing and hiding sheet tabs (turning tabbed views on or off) for published content refers to navigation in a published workbook. When sheet tabs are shown, published content has navigational sheet tabs along the top of each view.

This setting also impacts how permissions function and may have security implications (see note).

Note: It's possible to have the **View** capability for a view without the **View** capability for the workbook or project that contain it. Normally if a user lacks the View capability for a project and workbook, they wouldn't know those assets exist. If they have the View capability for a view, however, a user may be able to see the project and workbook name

when looking at the view, such as in the navigational breadcrumb. This is expected and accepted behavior.

Turn off tabbed views to allow independent view permissions

Although it isn't recommended as a general practice, there are times when it can be useful to set permissions on views independently of the workbook that contains them. To do so, three conditions must be met:

1. The workbook must be published—there's no way to set view permissions during publishing.
2. The workbook must be in a customizable project.
3. The workbook can't show sheets as tabs (tabbed views must be hidden).

When a workbook shows sheets as tabs, all views inherit the workbook permissions and any changes to the workbook permissions affect all of its views. **When a workbook in a customizable project doesn't show tabbed views, all views assume the workbook permissions upon publication, but any subsequent changes to the workbook's permission rules *won't be inherited by the views*.**

Changing the configuration of sheets as tabs on a published workbook will also impact the permission model. Show Tabs overrides any existing view-level permissions and reinstate the workbook-level permissions for all views. Hide Tabs breaks the relationship between the workbook and its views.

- To configure sheets as tabs on a published workbook, open the Actions menu (...) for the workbook and select **Tabbed Views**. Choose **Show Tabs** or **Hide Tabs** as desired.
- To configure sheets as tabs during publishing, refer to [Show sheets as tabs](#).
- To set view-level permissions, see Set permissions on assets.

Important: In a customizable project, any modifications to the workbook-level permissions won't be applied if navigational sheet tabs are hidden (aka tabbed views are off). Changes to permissions must be made on individual views.

Collections

For information on managing permissions in Collections, refer to [Collections](#).

Permission Capabilities and Templates

Permissions are made up of capabilities, or the ability to perform a given action on a piece of content, such as view, filter, download, or delete. Each row in the Permission Rules area of the dialog is a *permission rule*. Permission rules are the setting for each capability (allowed, denied, or unspecified) for the group or user in that row. Permission rules have *templates* available that make it easier to assign capabilities quickly. Permission rules can also be copied and pasted.

Note: In the permission dialog for projects, there are tabs for each content type: **Projects**, **Workbooks**, **Data Sources**, **Data Roles**, **Flows**, **Ask Data Lenses**, **Metrics** and—if you have the Data Management—**Virtual Connections**, **Databases**, and **Tables**. (Virtual connections were added in Tableau Server 2021.4 and Tableau Cloud December 2021. Databases and tables were added in Tableau Server 2022.3 and Tableau Cloud October 2022.) When a permission rule is added, the default for all capabilities across all content types is Unspecified. To allow or deny capabilities for each content type, you must go to each tab in turn. In the permission dialog for a specific piece of content, there are no tabs and the permission rules only apply to that piece of content.

Templates

Templates group sets of capabilities that are often assigned together based on common user scenarios, **View**, **Explore**, **Publish**, and **Administer**. When you assign a template, its included capabilities are set to **Allowed**, with the rest left as **Unspecified**. The templates are cumulative, so the Explore template includes everything from the View template plus additional capabilities. All content also has a template for **None** (which sets all capabilities to unspecified) and **Denied** (which sets all capabilities to denied).

Templates are meant to be a starting point and can be adjusted after they are applied. Capabilities can also be granted or denied without using a template at all. In both cases, the template column then shows **Custom**.

Copy and paste permissions

If there is a permission rule that needs to be assigned to multiple groups or users, you can copy and paste from one rule to another. You can't copy from or paste onto a rule that involves Project Leader status.

1. Open the action menu (...) for the existing rule you want to copy from and select **Copy Permissions**. This is available only when the rule is not in edit mode.
2. Select an existing rule you want to paste over. You can also create a new rule by clicking **+ Add Group/User Rule** and selecting a group or user.
3. Open the action menu (...) and select **Paste Permissions**.

Capabilities

Each content type has specific capabilities:

Projects

Projects have only two capabilities and two templates. For more information about project leaders and how to assign them, see Project administration.

View template

 **View** lets a user see the project. If a user hasn't been granted the view capability, the project won't be visible to them. Granting the view capability for a project does not mean a user can see any content in the project, just the existence of the project itself.

Publish template

 **Publish** lets a user publish content to the project from Tableau Desktop or Tableau Prep Builder. The publish capability is also required to move content into the project or save content to the project from web authoring.

Workbooks

View template

 **View** lets a user see the workbook or view. If a user hasn't been granted the view capability, the workbook won't be visible to them.

 **Filter** lets a user interact with filters in the view, including keep only and exclude filters. Users lacking this capability won't see filter controls in the view.

 **View Comments** lets a user view the comments associated with the views in a workbook.

 **Add Comments** lets a user add comments to views in a workbook.

 **Download Image/PDF** lets a user download each view as a PNG, PDF, or PowerPoint.

 **Download Summary Data** lets a user view the aggregated data in a view, or in the marks they've selected, and download that data (as a CSV).

Explore template

 **Share Customized** lets users add their custom views to the list of "Other Views" visible on a workbook.

- When this capability is denied, users won't see the "Make visible to others" option when they create a custom view. For more information, see [Use Custom Views](#). This capability doesn't impact the ability to share a custom view with the share dialog or by copying the link.

 **Download Full Data** lets a user view the underlying data in a view, or in the marks they've selected, and download that data (as a CSV).

 **Web Edit** lets a user edit the view in a browser-based authoring environment.

- Note that creating new content in the browser or saving views from the web edit interface requires a specific combination of capabilities. For more information, see [Web Editing and Web Authoring](#).
- The Web Editing feature must also be enabled for the entire site or even users with this capability allowed won't be able to web edit. For more information, see [Set a Site's Web Authoring Access](#).

Run Explain Data lets a user run Explain Data on marks in editing and viewing mode.

- Note that for Explain Data to be displayed as an option when a user selects a mark in a workbook, the feature must also be enabled as a site setting. To make Explain Data available in viewing mode, the feature must also be allowed by the author from within a workbook in Explain Data settings. For more information, see [Control Access to Explain Data](#).

Publish template

Download Workbook/Save a Copy lets a user download a packaged workbook (as a TWBX). Lets a user save (publish) a copy from the web edit interface as a new workbook.

Overwrite lets a user overwrite (save) the content or asset on the server.

- When allowed, the user can re-publish a workbook, data source, or flow, or save a workbook or flow in web authoring, thereby becoming the owner and gaining access to all permissions. After this change in ownership, the original owner's access to the workbook is determined by their permissions just like any other user.

Create/Refresh Metrics lets a user create metrics on the views in a workbook and lets any metrics that a user creates from those views refresh. For more information, see [Create and Troubleshoot Metrics](#).

Administer template

Move lets a user move workbooks between projects. For more information, see [Move content](#).

Delete lets a user delete the workbook.

Set Permissions lets a user create permission rules for the workbook.

Views

In a workbook that is not in a locked project and does not show sheets as tabs for navigation, views (sheets, dashboards, stories) inherit the workbook permissions at publication, but any changes to permission rules must be made on individual views. View capabilities are the same as those for workbooks, except for **Overwrite**, **Download Workbook/Save a Copy**, and **Move** which are only available at the workbook level.

We recommend showing navigational sheet tabs whenever possible so views continue to inherit their permissions from the workbook.

Data Sources

View template

View lets a user see the data source on the server.

Connect lets a user connect to a data source in Tableau Desktop, Tableau Prep Builder, Ask Data, or web editing.

- If a workbook author embeds their credentials to a published data source in a published workbook, they are essentially embedding their **Connect** capability. Therefore, users can see the data in the workbook regardless of their own **Connect** capability for that data source. If the workbook author doesn't embed their credentials to the published data source, the user needs their own **Connect** capability to the data source to consume the workbook. For more information, see [Data access for published Tableau data sources](#).
- A user must have the **Connect** capability for a data source to use Ask Data and to create Ask Data lenses. For more information, see [Enable Ask Data for Sites and Data Sources](#).

Explore template

 **Download Data Source** lets a user download the data source from the server (as a TDSX).

- Cube data sources, like those for Microsoft Analysis Services or Oracle Essbase connections, must be used locally. To download the published data source to Tableau Desktop, the user must have the Download capability. For more information, see Cube Data Sources.

Publish template

 **Overwrite** lets a user publish a data source to the server and overwrite the data source on the server.

Administer template

 **Delete** lets a user delete the data source.

 **Set Permissions** lets a user create and edit permission rules for the data source.

Other types of assets

	View template	Explore tem- plate	Publish tem- plate	Administer tem- plate
Flows	 View lets a user view the flow.	 Download flow lets a user download the flow (as a TFLX).	 Run lets a user run the flow.  Overwrite lets a user publish a flow and overwrite the published flow.	 Move lets a user move assets between projects. For more information, see Move content.

Delete lets a

user delete the
asset.

Set Per-

missions lets a
user create per-
mission rules for
the asset.

Data Roles	 View lets a user view data roles.	n/a	 Overwrite lets a user publish data roles, overwrite published data roles, and edit published data roles' synonyms.
Metrics	 View lets a user view metrics.	n/a	 Overwrite lets a user overwrite a metric and edit a metric's details.
Ask Data Lenses	 View lets a user see the lens.	n/a	 Overwrite lets a user edit the lens.
Virtual Connections	 View lets a user see the virtual connection.  Connect* lets a user connect to data using a virtual connection.	n/a	 Overwrite lets a user edit the virtual connection.
Databases	 View lets a user see the database.	n/a	 Overwrite lets a user edit the metadata for the data-

				base.
Tables	 View	lets a user see the table.	n/a	 Overwrite lets a user edit the metadata for the table.
Collections	 View	lets a user view collections.	n/a	n/a

*By default, virtual connections have a Custom template that sets the View capability to Allowed but not the Connect capability. Be sure to set the Connect capability to Allowed so users can connect using the virtual connection.

Manage Permissions with Projects

Projects can simplify permission management with features such as nested projects, project visibility, non-admin project leaders, and locking permissions.

Tip: How permissions are set at the project level is important, especially for the Default project. When a new top-level project is created, it inherits its default permission rules (for all content types) from the Default project. When a new project is created nested inside another project, the child project inherits its default permission rules from the parent project.

Project administration

Projects are containers used to organize and manage access to content. By giving non-administrators privileges to manage projects, certain content administration tasks can be handled at the project level.

Project Leaders: Projects can have project leaders, users who have been set as a **project leader**. This setting automatically grants a user their maximum capabilities—depending on their site role—for that project and all content in that project. Project leaders with site

role of Explorer (can publish) and above have all capabilities. Project leaders are essentially local admins for the project without access to site or server settings.

Hierarchy: Only administrators can create top-level projects. Project owners and project leaders can create nested projects inside their projects.

Project owners and leaders have full administrative access to the project and its content, as well as any nested projects it contains. In a hierarchy, project leaders are implicitly given project leader access to all child content. To remove project leader access, you must do so at the level in the hierarchy where the role was explicitly assigned.

Ownership: A project can have multiple project leaders, but each project has exactly one owner. By default, a project is owned by the user who created it.

A project's owner can be changed by the existing owner or an administrator. (Project leaders can't change project ownership, only content ownership). Projects can be owned by users with a site role of Explorer (can publish), Creator, or administrator. Project ownership can be changed even if a project is locked.

Deleting: Most content can only exist inside a project. Only administrators can create and delete top-level projects, but project leaders can create or delete nested projects.

Deleting projects also deletes all the Tableau content and nested projects they contain. To delete a project without losing its content, move the content to another project first. Deleting projects can't be undone.

External assets are handled differently. They don't have to be in a project. External assets aren't deleted if their project is deleted and continue to appear in **External Assets**. See [External assets that aren't in projects](#) for more information.

For a deeper dive into project administration, see [Use Projects to Manage Content Access and Add Projects and Move Content Into Them](#).

Special projects

Default: The project named "Default" is a special project. When other top-level projects are created, they use the Default project as a template, and copy all their permissions rules from it (but not the **Asset permissions** setting). The **Default** project can't be deleted, moved, or renamed, but its description can be changed. It has no owner by default, but one can be assigned.

External Assets Default Project: If you have the Data Management license with Catalog enabled, the project named "External Assets Default Project" appears when Catalog needs to move new or existing external assets to it. Catalog puts new external assets and external assets from deleted projects in the **External Assets Default Project**. The project has no permissions rules by default, so server administrators and site administrators are the only users who can see it unless permissions are added. It can't be deleted, moved, or renamed, but its description can be changed. It has no owner by default, but one can be assigned.

Set a project leader

Project leaders are users who have administrator-like access for a specific project or project hierarchy.

To assign project leader status to a group or user

1. Open the permission dialog for the appropriate project.
2. Select an existing permission rule, or click **+ Add Group/User Rule** and chose the desired group or user.
3. Open the action menu (...) for that permission rule and select **Set Project Leader....**

Note: If the action menu includes an option for **Enable "Set Project Leader"**, this needs to be selected before the group or user can be set as a project leader. This option only appears when that group or user was denied the Project Leader capability (prior to 2020.1). That denied capability needs to be removed before they can be set as a project leader.

After a permission rule establishes a project leader, the templates and capabilities can't be edited because all capabilities are allowed for project leaders. If a project leader is established on a project that contains nested projects, they have inherited project leader status on all nested projects and their content.

Project leader status is always applied downward through the entire project hierarchy and can only be removed from the level where it was set. To remove project leader status, follow the same steps but select **Remove as Project Leader** from the action menu. After a group or user has been removed as project leader, that permission rule has all capabilities set to Unspecified. This may mean their access to and capabilities for that project is removed if there's no other permission rule giving them permissions to the content. To keep their access to the project and its content, they need to have capabilities set like any other group or user.

Note: Project leaders can refresh extracts in their projects in most circumstances. They can't refresh extracts if they're only the project leader of a nested project (instead of a top-level project) and the top-level project is *locked (including nested projects)*.

Lock asset permissions

Permission rules set at the project level act as a default for content saved in that project and any nested projects it contains. Whether those project-level default rules are enforced or only preliminary depends on the **Asset permissions** setting. This setting can be configured in two ways, either **Locked** (recommended) or **Customizable**. Locking a project removes the ability for content owners to modify the permission rules on their content. Locking permissions can be applied to nested projects or just to the parent project itself.

- When **Asset permissions** is **Locked** (including nested projects), permission rules set at the project level are enforced for all assets in the project and all nested projects.
- When **Asset permissions** is **Locked** (*not* including nested projects), permission rules set at the project level are enforced for assets in the project. Nested projects can be configured independently with their own permission rules and set as locked or customizable.

- When **Asset permissions** is **Customizable**, permission rules set at the project level are applied to all assets in the project by default. However, permission rules can be modified for individual assets during or after publishing.

Note: Whether permission rules are locked or customizable, the permissions on content are always applied. *Locked* and *customizable* refer only to how project-level permissions are inherited by content in the project and who can change them. Even in a project with customizable permissions, only specific users can modify permissions (content or project owner, project leader, admins, or those with the Set Permission capability).

In a locked project:

- The project permission rules per content type are applied to all assets.
- Only administrators, project owners, and project leaders can modify permissions.
- Content owners lose the Set Permission capability but retain all other capabilities on their content.
- Permissions are predictable for all content in the project.

In a customizable project:

- The project permission rules are applied by default when content is published into the project or nested projects are created, but permissions can be modified during publication or after the content is created.
- Any user with the Set Permissions capability can modify permission rules for that content.
- Content owners have all capabilities on their content.
- Permissions can be different across content in the project.

Set asset permissions (lock a project)

New top-level projects inherit all initial permission rules from the Default project but not the **Asset permissions** setting, which is set to **Customizable**. This can be changed to **Locked** if desired.

To configure **Asset permissions**:

1. You must be logged into the site as an administrator, project owner, or project leader
2. Open the permissions dialog for a project
3. Next to **Asset permissions** in the upper left, click the **Edit** link and select the desired option in the **Asset permissions** dialog

Asset Permissions

☒ **Locked:** Assets inherit project permission rules. Asset-level permissions can't be modified. (Recommended)

☒ Apply to nested projects

☐ **Customizable:** Assets starts with project permission rules. Permissions can be modified by users authorized to do so.

Cancel Save

Note: If the upper left corner doesn't show an **Edit** link in step 3 above, you may be on the permissions dialog for a (a) nested project or a piece of content in a locked project, in which case the link should bring you to the managing project, (b) piece of content in a customizable project, which won't show anything, or (c) view, which will indicate how the view permissions are tied to the workbook. For more information on the interplay of permissions for views and workbooks, see [Show or Hide Sheet Tabs](#).

Change asset permissions

When the **Asset permissions** setting for a project is changed, the outcome depends on the new setting. Changes to permission rules in a locked hierarchy must be done at the level of the managing project.

Changing from	Changing to	Outcome
Locked (including nested projects)	Locked	Doesn't modify existing permission rules. Any nested projects become customizable.

	Customizable	Doesn't modify existing permission rules, though they become customizable. Any nested projects become customizable.
Locked	Locked (including nested projects)	Overwrites existing custom permission rules for all nested projects and their content. This can't be undone.
	Customizable	Doesn't modify existing permission rules, though they become customizable. Any nested projects retain their content permission settings and permission rules.
Customizable	Locked (including nested projects)	Overwrites existing custom permission rules for content in the project, and all nested projects and their content. This can't be undone.
	Locked	Overwrites existing custom permission rules for content in the project. This can't be undone. Any nested projects retain their permission rules and remain customizable.

Move projects and content

Move Tableau content and external assets

When *Tableau content* or *external assets* are moved between projects with different permission settings, **Asset permissions** settings determine the logic of how permissions are applied.

- Moving assets into a locked project overrides the existing permission rules and enforce the destination's permissions.
- **Moving assets into a customizable project maintains the existing permission rules on the asset.**

Note: Prior to Tableau Server 2022.3 and Tableau Cloud June 2022, external assets couldn't be in projects, and permissions on tables were managed through the **Table permissions** setting of the parent database. Beginning with Tableau Server 2022.3 and Tableau Cloud June 2022, external assets can be in projects. If a database or a table is moved into a project, older settings to control table permissions through the database are ignored, and the database or table permissions follow the logic of other assets.

Move projects

When a *project* is moved into another project, the permissions settings on the item being moved are maintained unless the destination project is scoped to include nested projects. (Project permissions in this case mean the View and Publish capabilities for the project itself.)

- If the destination project is set to **locked (including nested projects)**, the permissions for the project being moved *and its content* are overwritten.
- If the destination project is set to **locked** (not including nested projects), the permissions for the project being moved aren't overwritten. Whether the moved project is locked or customizable is preserved from its original setting.
- If the destination project is set to **customizable**, the permissions for the project being moved aren't overwritten but they're now editable.

If the project being moved was previously nested under a parent that was *locked (including nested projects)*, when moved, the project takes on the setting of *locked (including nested projects)* and becomes the managing project for any projects it contains.

Note: This is the same outcome if a project is moved to become a top-level project.

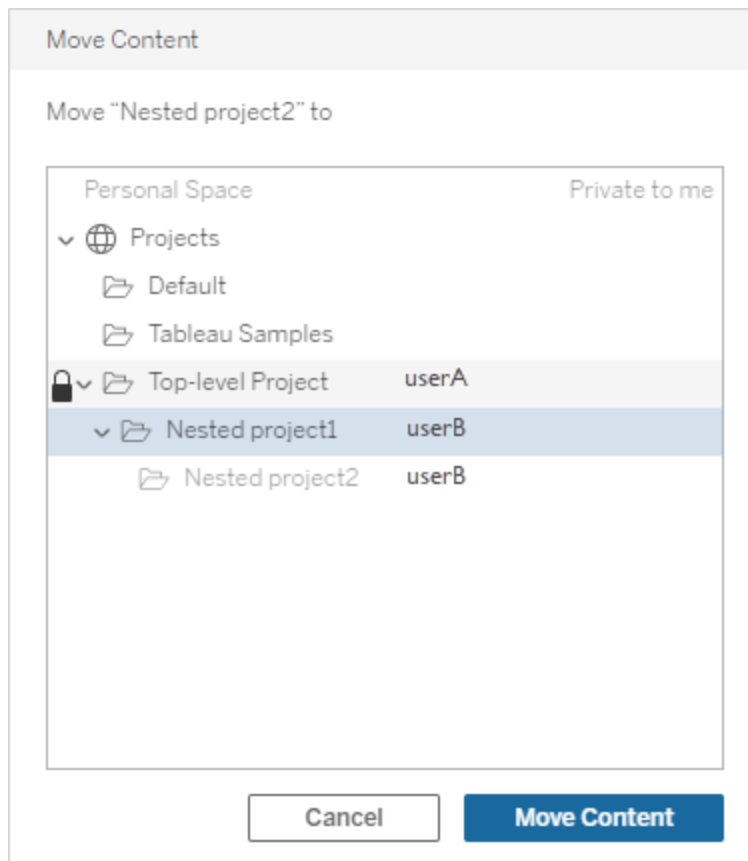

Use care moving locked nested projects

Moving nested projects inside *locked (including nested projects)* environments can be tricky. A project can be moved into situation that prevents the user from moving it out again.

If a nested project is owned by a different user than the managing project, and the managing project is set to *locked (including nested projects)*, a nested project can wind up unable to be moved by anyone except an admin.

For example, consider a locked (including nested projects) top-level project owned by userA, and two nested projects owned by userB. If userB moves one nested project inside the other, they aren't then able to move it back out—and neither is userA.

- UserB can't move **Nested project2** because they don't have rights to move rights on **Top-level Project** as a destination.
- UserA can't move **Nested project2** because they don't have move rights on it.
- A project leader on **Top-level Project** can't move it even though project leader trickles down to nested projects.
- Only an admin can move **Nested project2** in this setup.

Collections

Unlike projects, which contain content, a collection can be thought of as a list of links to content. Project permissions can be inherited by the content in the project, but permissions for a collection have no effect on the content added to the collection. This means that different users might see different numbers of items in a collection, depending on which items they have permission to view. To make sure that users can see all items in a collection, adjust the permissions for those items individually.

Permissions for a collection can be changed either by using the permissions dialog or by granting access upon sharing a collection, if you're an administrator or the collection owner. For more information, see [Manage Collection Permissions](#).

Private collections

When a collection is created, it's private by default. A private collection appears on the owner's My Collections page, but it doesn't appear in the list of all collections on a site. Private collections are simply collections with no permission rules added. Unlike other types of content, collections don't have the "All Users" group added by default. When you add permission rules to a collection, it's no longer flagged as private. To return a collection to a private state, remove the permission rules.

Private collections can be viewed by the collection owner as well as by administrators, whose site role gives them effective permissions to view all collections.

Effective permissions

A permission rule establishes who is impacted (a group or user) and what Capabilities they are **Allowed**, **Denied**, or **Unspecified**. While it seems straightforward to simply set a permission rule and have that be the whole story, whether a user has a capability may be unclear because of membership in multiple groups and the interplay of site roles and ownership with permission rules.

Multiple factors are evaluated in a specific order, yielding *effective permissions* on a piece of content.

Tip: To help keep things as straightforward as possible, we recommend (1) setting permission rules for groups instead of users, (2) managing permissions locked at the project level instead of setting permissions on individual content, and (3) deleting the All User group's permission rule or setting all capabilities to None.

A capability is allowed for a user if and only if the following three conditions are all met:

- The capability is within the scope of their site role.
- They have that capability:
 - based on a specific user scenario (such as being the content owner or a project leader, or they're an administrator site role),
OR
 - because they have been allowed the capability as a user,
OR
 - because they are both in a group that has been allowed the capability and no rules deny them the capability as a user or member of another group.
- There is no conflicting permissions settings at another content level that takes precedence.

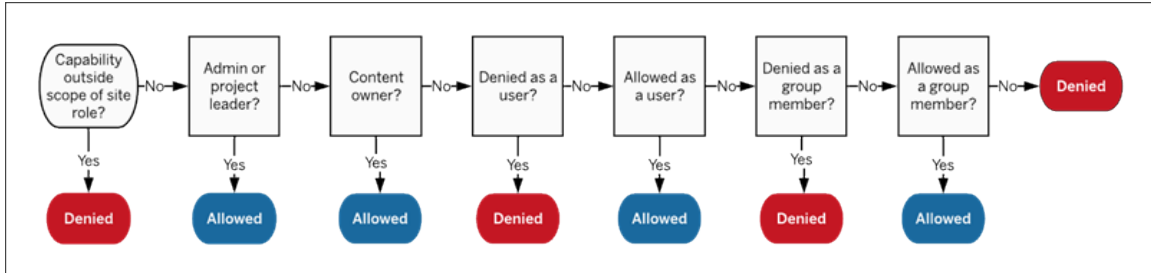

Any other situation denies the user the capability.

Hovering over a capability brings up a tooltip that explains the effective permission. Here are some common examples of why effective permissions—what the user can or can't do in actuality—might appear different than what a given permission rule states:

- A user might have a capability they are denied in a permission rule because their site role includes it (administrators).
- A user might have a capability they are denied in a permission rule because their user scenario allows it (because they own the content or are a project owner or leader).
- A user might lack a capability they are allowed in a permission rule because their site role doesn't allow it.
- A user might lack a capability they are allowed in a permission rule because a conflicting group or user rule denied it.
- A user might lack a capability they are allowed in a permission rule at one level of content (such as a workbook) because another level of content denied it (such as a view).

Evaluate permission rules

Permissions in Tableau are restrictive. Unless a capability is granted to a user, they are denied permission. The following logic evaluates if a capability is allowed or denied for an individual:

1. **Site role:** If a site role doesn't permit a capability, the user is denied. If the user's site role does permit the capability, then specific user scenarios are evaluated.
 - For example, a Viewer site role can't web edit. See General capabilities allowed with each site role for more information on what each site role can do.
2. **Specific user scenarios:**
 - If the user is an admin they have all capabilities on all content.
 - If the user is a project owner or project leader, they have all capabilities on all content in their projects.
 - If the user is the content owner, they have all capabilities* on their content.
 - If these scenarios do not apply to the user, then user rules are evaluated.

*Exception: Content owners won't have the **Set Permissions** capability in projects where permissions are locked. Only administrators, project owners, and project leaders can set permission rules in locked projects.

3. **User rules:** If the user is denied a capability, it is denied. If they are allowed a capability, it is allowed. If a capability is unspecified, then group rules are evaluated.
4. **Group rules:** If the user is in *any* group that is denied a capability, it is denied. If the user is in a group that is allowed a capability (and not in any groups that are denied that capability), it is allowed.
 - That is to say, if a user is a member in two groups, and one is allowed a capability and one is denied the same capability, the denial takes precedence for that user and they are denied.
5. If none of the above conditions apply, the user is denied that capability. In effect, this means that capabilities left as unspecified will result in denied.

A final effective permission of **Allowed** therefore occurs in three circumstances:

- Allowed by site role (Server Administrator, Site Administrator Creator, Site Administrator Explorer)
- Allowed because the user is the content owner, project owner, or project leader
- Allowed by a group or user rule (and not denied by a rule of higher precedence)

Denied occurs in three circumstances:

- Denied by site role
- Denied by a rule (and not allowed by a rule of higher precedence)
- Not granted by any rule

Evaluate permissions set at multiple levels

If **Asset permissions** are set to **Customizable**, it's possible to configure permission rules in multiple places. There are specific rules that determine what permissions are applied on the content.

- If there are nested projects, permissions set at the child level take precedence over permissions set at the parent level.
- Changes to permissions at the project level are not enforced for existing content.
- If there are permissions set on content (workbook, data source, or flow) during or after publication, these take precedence over rules set at the project level.
- If a workbook doesn't show navigational sheet tabs, any changes to the workbook-level permissions *won't* be inherited by the views and any changes to permissions must be done on the view.
- Configuring the workbook to show navigational sheet tabs will override existing view-level permissions and sync them with the workbook-level permissions. See [Show or Hide Sheet Tabs](#).

This image shows how capabilities are evaluated through multiple levels of content.

Permissions on views

In a workbook that is not in a locked project and does not show sheets as tabs for navigation, views (sheets, dashboards, stories) inherit the workbook permissions at publication, but any changes to permission rules must be made on individual views. View capabilities are the same as those for workbooks, except for **Overwrite**, **Download Workbook/Save a Copy**, and **Move** which are only available at the workbook level.

We recommend showing navigational sheet tabs whenever possible so views continue to inherit their permissions from the workbook. For more information, see [Show or Hide Sheet Tabs](#).

Effective permissions and on-demand access

When on-demand access is enabled for a group, you'll see an inline alert. On-demand access indicates that when permissions for Tableau content are dependent on the group, there might be users who are not provisioned on the site that can access the content. Users who might be accessing the content are not provisioned on the site and do not have effective permissions. As a result, these users are not listed in the Effective Permissions area. For more information, see [On-demand access using connected apps with direct trust](#) or [On-demand access using connected apps with OAuth 2.0 trust](#).

Permissions, Site Roles, and Licenses

Adding a user to Tableau Cloud requires an available license. (Users can also be added as unlicensed and configured so they will consume a license only when they first sign in. For more information, see [Grant License on Sign In](#).) For each site the user belongs to they have exactly one site role, restricted by their license. A user has permissions for content on the site, restricted by what their site role allows.

Licenses and site roles apply to users. Permission capabilities apply to content.

Licenses are assigned to a user when they are created (or sign in for the first time) on the Tableau Server or Tableau Cloud site. Users are licensed as a **Creator**, **Explorer**, or **Viewer**.

- License levels are consumed based on the maximum *site role* a user can have on that server.
 - Server Administrator, Site Administrator Creator, and Creator site roles use a Creator license.
 - Site Administrator Explorer, Explorer (can publish), and Explorer site roles use at least an Explorer license.
 - Viewer site role uses at least a Viewer license.
 - An unlicensed user can exist on the site, but they cannot sign in unless they were added with grant site role on sign in.
- For Tableau Server, a user consumes only one license per server, even if they are a member of multiple sites. If a user is a member of multiple sites, their required license

level is determined by their highest site role. (For example, if a user has a Creator site role in one site and a Viewer site role in two others, they consume a Creator license.)

Site roles are assigned to a user for each site they are a member of.

- Site roles determine the maximum capabilities a user can have in that site. (For example, a user with a site role of Viewer will never be able to download a data source even if that capability is explicitly granted to them on a specific data source.)
- Site roles do not inherently grant any capabilities in and of themselves—with the exception of the administrator site roles. Administrators always have all capabilities applicable to their license level.

Permissions consist of *capabilities*, like the ability to save to a project, web edit a workbook, connect to a data source, etc. They apply to group or user on a specific piece of content (project, data source, workbook, view, or flow).

- Permission capabilities are not given to a group or user in a vacuum but rather in the context of content. A user can have different capabilities for different content assets.
- Permissions are evaluated based on the interplay of a user’s site role and the permission rules for that user or any groups they are members of.
- Some actions such as web authoring might require combinations of capabilities. For more information, see Permission settings for specific scenarios.

Site roles and their maximum capabilities

These tables indicate what capabilities are available for a site role. There may be other ways for a user with a site role to perform a similar action. For example, although Viewers can’t be given the **Share Customized** capability to make their custom views visible to others on the workbook, they can share custom views by copying the view URL. See General capabilities allowed with each site role for more information on what each site role can do.

* Although the Explorer role can be given the **Move** capability, they can't have the **Publish** capability on a project and therefore there is no place for them to move content to. The **Move** capability should therefore be considered not possible for Explorer site roles.

Quick Start: Permissions

A permission rule is a set of capabilities that defines what access a group or user has to a piece of content, such as a workbook, project, or data source.

To efficiently manage permissions:

- Remove permissions from the **All Users** group before creating more groups
- Configure template permissions on the **Default** project before creating more projects
- Manage permissions for groups, not users
- Manage permissions for projects, not content

Create group permission rules for projects

For details on the following steps, see the [main article on permissions](#). This Quick Start guide is an overview and doesn't capture many important details about permissions and permission management.

1. Add users to groups

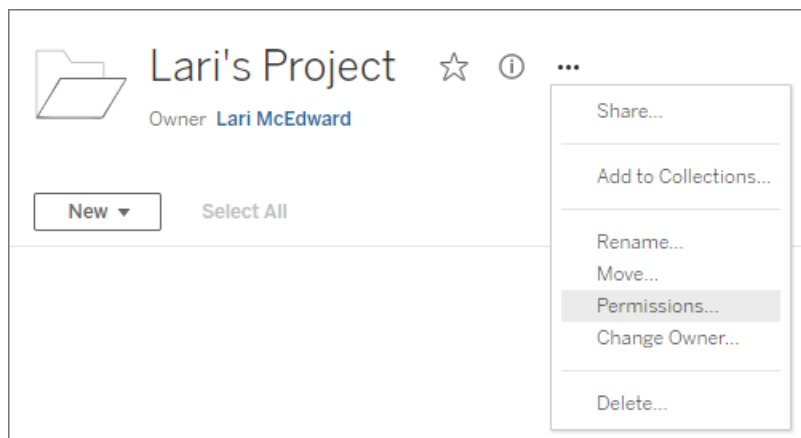

A common way to manage permissions is to use groups for users who should have the same permissions.

1. If necessary, add users to the site.
2. Within a site, select **Groups**.
3. If necessary, create a group using the **Add Group** option.
4. Click a group name to open it, then use the **Add Users** button to add existing users to the group.

2. Access project-level permissions settings

The **Explore** page displays the content on the site. Use the dropdown to display Top-Level Projects or All Projects (to see nested projects as well).

Navigate to the project you want to update, open the **Actions (...)** menu, then select **Permissions**.

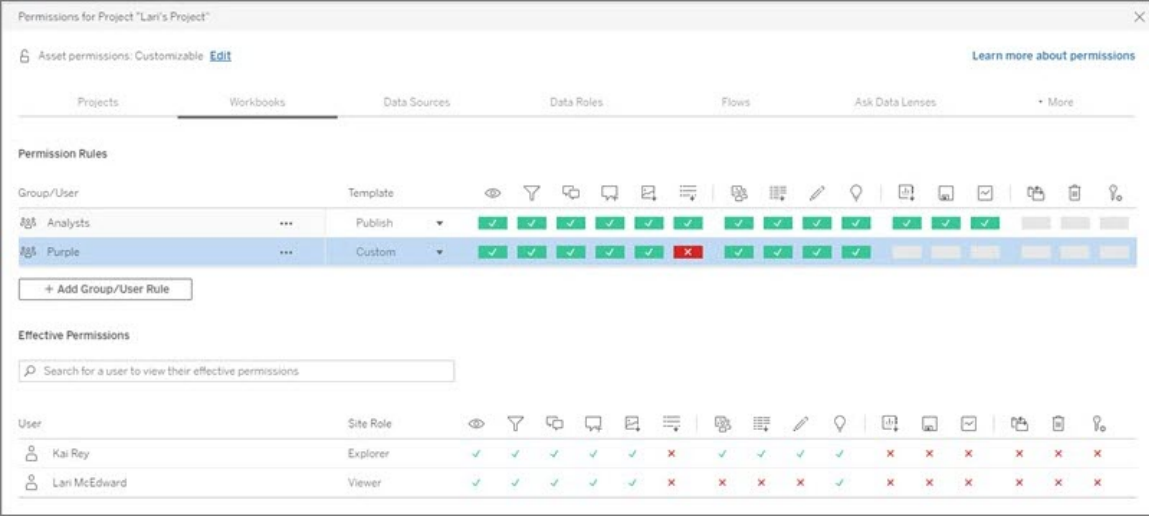

3. Create a permissions rule

Select **+ Add Group/User Rule** to create a new permission rule.

The template drop-down offers a shortcut to apply an initial set of capabilities for the group.

If desired, customize the permission rule by clicking a capability to set it to **Allowed** or **Denied**, or leave it **Unspecified**.

Whether a user can set permissions is based on their site role, content ownership, and how their **Set Permissions** capability is set.

4. View a user’s effective permissions

After you save the permissions rule for the group, you can view the effective permissions for each user. Click a group name to see the group's users and their permissions. Hover over a capability box to see a tooltip with details on whether a capability is allowed or denied.

Site roles

A user’s site role determines the maximum permissions allowed for that user.

- Server and site administrators can access all site content and take actions on it.
- Owners always get full access to the content they’ve published. When the parent project permissions aren’t locked, owners can change permissions for their published content.

For more information, see [Set Users’ Site Roles](#) and [Use Projects to Manage Content Access](#).

Permission logic

- **Denied** takes precedence over **Allowed**.
- **Unspecified** results in **Denied** if no other permissions are specified.
- Specific user permissions on content take precedence over group permissions on content. In other words, user permissions trump group permissions.

For more information, see [Effective permissions](#).

Manage Content Ownership

When you publish a data source or workbook on Tableau Server or when you create a project, you become its *owner*. A content owner, a project leader with an appropriate site role, or an administrator can change ownership of a content asset. After ownership is reassigned, the original owner has no special connection to the content item, and their ability to access it is determined by their permissions on the project or that specific item.

Who can change or be given ownership, by content type

Whether you can change or be given ownership depends on your permissions and your relationship to the content asset, as described in the following table.

Note: Full project leader access is available only with some site roles. For information, see Project-level administration.

Content asset type	Who can change ownership	Who can be given ownership
Top-level projects	Server administrator ¹ Site administrator	Server administrator Site administrator (Creator and Explorer) Creator Explorer (can publish)
Child (nested) projects	Server administrator Site administrator Project owner	Any administrator or owner, excluding Explorer and Viewer.
Workbooks and data	Server administrator	Server administrator

sources	<p>Site administrator</p> <p>Workbook or data source owner</p> <p>Project leader or owner of the project that contains the item</p>	<p>Site administrator</p> <p>Creator</p> <p>Explorer</p> <p>Viewer</p>
Metrics	<p>Server administrator</p> <p>Site administrator</p> <p>Metric owner</p> <p>Project leader or owner of the project that contains the item</p>	<p>Any administrator or user of the site, excluding Explorer and Viewer.</p>
Ask Data lenses	<p>Server administrator</p> <p>Site administrator</p> <p>Lens owner</p> <p>Project leader or owner of the project that contains the item</p>	<p>Any administrator or user of the site, excluding Explorer and Viewer.</p>
Flows	<p>Server administrator</p> <p>Site administrator</p>	<p>Starting in version 2021.2, server and site administrators can only change the owner to themselves.</p>

Data Roles	Server administrator Site administrator Data role owner Project leader or owner of the project that contains the item	Any administrator or user of the site, excluding Explorer and Viewer.
Collections	Server administrator Site administrator Collection owner	Server administrator Site administrator Creator Explorer Viewer
Virtual Connections²	Server administrator Site administrator Virtual connection owner	Server administrator Site administrator Creator

¹ The Server Administrator site role applies to Tableau Server only; not Tableau Cloud.

² Virtual connections require Data Management. See About Data Management for details.

Note that to edit a virtual connection, you must have the database credentials.

Considerations for changing content ownership

- Before you remove a user from Tableau Server, make sure they do not own any content assets.

If the user does own content, you must first reassign ownership of those assets before you can delete the user. Otherwise, their site role is set to **Unlicensed**, but they are not deleted, and only an administrator can take certain actions on that content.

- If you change the ownership of a workbook or data source that includes embedded credentials to connect to underlying data, the embedded credentials will be deleted. For flows, embedded credentials are preserved when changing ownership. Connections to published data sources are authenticated using the flow owner and authorized based on their permissions.

You can update the embedded credentials by editing the connection information on Tableau Server. For more information, see [Edit Connections](#). Alternatively, the new owner can download the flow, workbook, or data source and open the item in Tableau Desktop to update the embedded credentials and then re-publish the content.

- If you do not lock permissions to projects, make sure users you give content ownership to know your permissions guidelines, or you account for permissions as you change ownership. In unlocked projects, by default, content owners can set permissions on their content. For more information, see [Permissions](#).
- While it is possible to change the owner of a metric to a user with a site role of Viewer or Explorer, it is not recommended, because doing so will cause the metric refresh to be suspended. A site role of Creator or Explorer (can publish) is required to refresh, overwrite, or delete a metric.

Change the owner of a content resource

1. Sign in to the Tableau Server web environment, and from the navigation menu, select **Explore**.
2. Navigate to the content you want to assign to someone else.
 - If you want to reassign multiple of the same type of content, for example, multiple workbooks, select the content type from the drop-down menu.

Tableau Server on Windows Help

- If you want to reassign multiple items within the same project, navigate to the project.

If you're not sure where to find a child project, display filters, and select **Show all projects**.

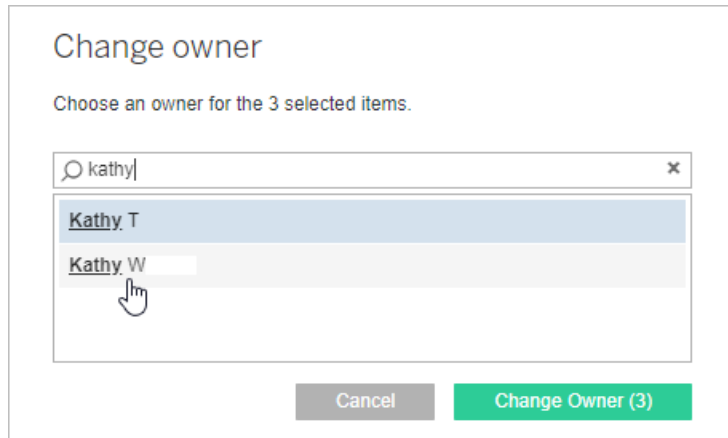

- If you want to reassign multiple content items with the same owner, find the user on the **Users** page.

3. Select the items you want to reassign, and then select **Actions > Change Owner**.

The other menu commands you see will depend on the content type.

4. Type the name of a user or select a user from the list.

5. Click **Change Owner**.

Manage Permissions for External Assets

Tableau Cloud and Tableau Server provide a space for accessing and managing published content. When Tableau Cloud or Tableau Server is licensed with Data Management, you have access to Tableau Catalog. Tableau Catalog adds a complementary space and a set of features across your site to track and manage metadata and lineage of external assets used by the content published to your site.

Tableau Catalog indexes content and assets

Catalog discovers, tracks, and stores metadata from the content that you publish to Tableau Cloud or Tableau Server.

Catalog indexes metadata for the following:

- **Tableau content:** workbooks, data sources, flows, projects, metrics, virtual connections, virtual connection tables, users, and sites
- **External assets:** databases and tables associated with Tableau content

Catalog classifies the metadata of any data that comes from outside the Tableau environment as external assets. The data that comes from outside the Tableau environment is stored in many different formats, such as a database server or a local .json file.

Catalog tracks only the metadata of the external data and does not track the underlying data in any form (raw or aggregated).

Catalog metadata includes the following:

- **Lineage information** or the relationship between items. For example, the Sales table has a relationship with both the Superstore data source and the Superstore Sample workbook.
- **Schema information.** Some examples include:
 - Table names, column names, and column types. For example, Table A contains Columns A, B, and C, which are types INT, VARCHAR, and VARCHAR.
 - Database name and server location. For example, Database_1 is a SQL Server database at <http://example.net>.
 - Data source name, and the names and types of the fields the data source contains. For example, Superstore data source has fields AA, BB, and CC. Field CC is a calculated field that refers back to both field AA and field BB.
- **User curated, added, or managed information.** For example, item descriptions, certifications, user contacts, data quality warnings, and more.

How does Tableau Catalog work?

Tableau Catalog indexes all content published to Tableau Cloud or Tableau Server to track lineage and schema metadata. For example, the metadata comes from workbooks, packaged workbooks, data sources, and the Tableau Server or Tableau Cloud repository.

As part of the indexing process, lineage and schema metadata about external assets (databases and tables) used by the published content are also indexed.

Note: In addition to accessing Catalog from Tableau Cloud or Tableau Server, indexed metadata can also be accessed from the Tableau Metadata API and Tableau Server REST API. For more information about the Tableau Metadata API or metadata methods in the REST API, see [Tableau Metadata API](#) and [Metadata Methods](#) in the Tableau Server REST API, respectively.

Permissions on metadata

Permissions control who is allowed to see and manage external assets and what metadata is shown through lineage.

Note: If Tableau Cloud or Tableau Server is not licensed with Data Management, then by default, only admins can see database and table metadata through the Tableau Metadata API. This default can be changed to use "derived permissions," as described below.

Access metadata

The permissions used to access metadata through Catalog (or Metadata API) work similarly to permissions for accessing content through Tableau Cloud or Tableau Server, with some additional considerations for sensitive data that can be exposed through lineage and the capabilities granted on external assets.

Permissions on Tableau content

Catalog follows the view and manage capabilities that are already in place on existing Tableau content to control the metadata that you can see and manage on Tableau content. For more general information on these capabilities, see [Permissions](#).

Permissions on external assets using derived permissions

When Tableau Cloud or Tableau Server is licensed with Data Management, by default Catalog uses *derived permissions* to automatically grant you capabilities to external assets in the following scenarios:

For **View** capability:

- If you are the owner of a workbook, data source, or flow, you can see the database and table metadata used *directly* by that workbook, data source, or flow. See [Additional notes about lineage](#).

- If you are a project owner or project leader, you can see all the database and table metadata used by the content published to your project.
- Embedded files use the permissions of the source content (such as the workbook, data source, or flow), rather than the derived permissions of the external asset (the database or table). For example, if you can see a workbook with an embedded file, you can see the embedded file and its metadata used by that workbook.

For both **Overwrite** and **Set Permissions** capabilities:

- If you are the owner of a flow, you can edit and manage permissions for the database and table metadata used by the flow output.

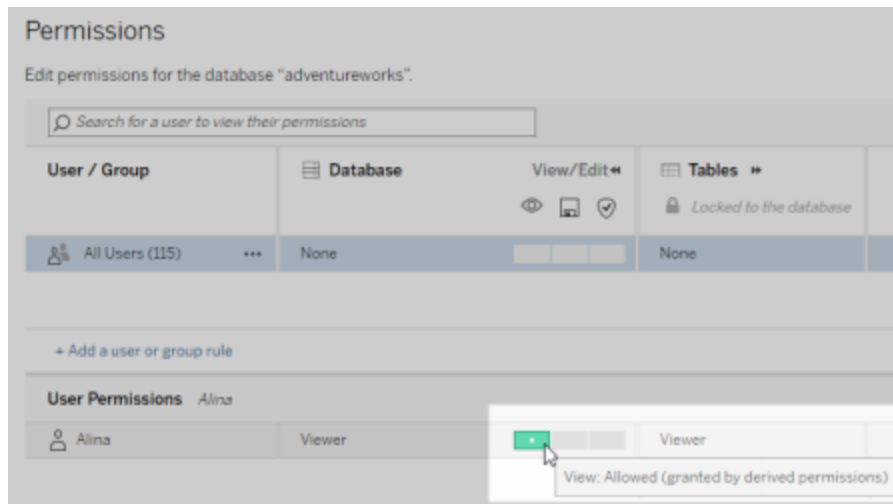

Note: In the case of flows, the capabilities mentioned above apply only after the flow has been run successfully at least once under the current owner of the flow.

Check permissions

As an admin or someone who has been given the capability to set permissions for an asset, you can validate who has derived permissions by following the steps below.

1. Sign in to Tableau Cloud or Tableau Server.
2. From the left navigation pane, click **External Assets**.
3. From the drop-down menu, select **Databases and Files** or **Tables**.
Note: Local files, like .json or .csv files are grouped as external assets under **Databases**.
4. Select the check box next to the database or table whose permissions you want to modify, and then select **Actions > Permissions**.
5. In the Permissions dialog box, click **+ Add Group/User Rule** and start typing to search for a group or user.

6. Validate the permissions by clicking a group name or user name in the permission rules to see the effective permissions below.

Order of precedence for derived permissions on external assets

When derived permissions are configured for your Tableau Cloud site or Tableau Server, each user's level of access to external assets depends on the associated Tableau content and the order of precedence of rules Tableau uses for its content.

Tableau follows the rules below, continuing on to the next rule, only if the current rule evaluates to "denied." If any rule evaluates to "allowed," the capability is allowed and Tableau stops evaluating. This rules list is based on the Permissions.

For **View** capability:

1. Admin role
2. License
3. Project leader (Tableau content)
4. Project owner (Tableau content)
5. Content owner (Tableau content)

6. *Derived permissions* (applies only to external assets and the View capability)
 - a. Admin role
 - b. License
 - c. Project leader (external assets)
 - d. Project owner (external assets)
 - e. Content owner (external assets)
7. Explicit permissions

For **Overwrite** and **Set Permissions** capabilities:

1. Admin role
2. License
3. Project leader (Tableau content)
4. Project owner (Tableau content)
5. Content owner (Tableau content)
6. Explicit permissions (Tableau content)
7. *Derived permissions* (applies only to external assets and the Overwrite and Set Permissions capabilities for flow outputs)
 - a. Admin role
 - b. License
 - c. Project leader (external assets)
 - d. Project owner (external assets)
 - e. Content owner (external assets)

Turn off derived permissions

As an admin, you can turn off the derived permissions default setting for a site in favor of manually granting explicit permissions to databases and tables.

1. Sign in to Tableau Cloud or Tableau Server as an admin.
2. From the left navigation pane, click **Settings**.
3. On the General tab, under Automatic Access to Metadata about Databases and Tables, clear the **Automatically grant authorized users access to metadata about databases and tables** check box.

Note: Data quality warning messages on databases and tables that are visible to users though derived permissions remain visible to those users even when the check box is not selected.

Set permissions on individual external assets

In order to grant additional users permissions to view, edit (overwrite), and manage external assets, an admin can grant those capabilities explicitly on individual databases or tables for users or groups.

Starting with Tableau Server 2022.3 and Tableau Cloud September 2022, you can organize external assets in projects. Permissions inheritance for external assets works the same way as it does for Tableau content, as described in the [Permissions](#) topic, and can simplify permissions management.

Summary of permissions capabilities

The following table shows the capabilities you can set for external assets (databases and tables):

Capability	Description	Template
 View	See the database or table asset.	View
 Overwrite	Add or edit data quality warnings and descriptions of the database or table asset. Prior to version 2020.1, the Overwrite capability was called Save.	Publish
 Move	Move the database or table asset.	Administer
 Set Permissions	Grant or deny permissions for the database or table asset.	Administer

Set permissions on a database or table

To set permissions on databases or tables, use the following procedure.

1. Sign in to Tableau Cloud or Tableau Server as an admin or someone who has been granted the "Set Permissions" capability.
2. Find the database or table. You can do this through **Explore** (starting with Tableau Server 2022.3 and Tableau Cloud September 2022) if you know the current location of the database or table, or through **External Assets** to see a list of all databases, tables, and files.
 - **Explore** - From the left navigation pane, click **Explore** and locate the project the database or table is in.
 - **External Assets** - From the left navigation pane, click **External Assets**. From the drop-down menu, select **Databases and Files** or **Tables** (Note: Local files, like .json or .csv files are grouped as external assets under Databases.)
3. Select the check box next to the database or table whose permissions you want to modify, and then select **Actions > Permissions**.
4. In the Permissions dialog box, click **+ Add Group/User Rule** and start typing to search for a group or user.
5. Select a permission role template to apply an initial set of capability for the group or user, and then click **Save**. Available templates are: View, Publish, Administer, None, and Denied.
6. To further customize the rule, click a capability in the rule to set it to Allowed or Denied, or leave it unspecified. Click save when you are done.
7. Configure any additional rules you want for other groups or users.
8. Validate the permissions clicking a group name or user name in the permission rules to

see the effective permissions below.

External assets that are not in projects

Assets that Catalog discovered before the ability to move external assets into projects was released (Tableau Cloud June 2022 / Server 2022.3) will not be in a project unless they've been moved into one since then.

If an external asset is not in a project, permissions for external assets work as they did in Tableau Server 2022.1 and Tableau Cloud June 2022 and earlier. That is, database and table permissions are controlled independently of content in projects, and table permissions can be managed through database permissions. When permissions are set at the database level in this way, those permissions can serve as a template for any newly discovered and indexed child tables of that database. Furthermore, database permissions can also be locked so that the child tables will always use the permissions set at the database level.

Note: You cannot lock (or unlock) permissions to a database if the database is in a project.

To lock (or unlock) permissions to the database, use the following procedure:

Tableau Server on Windows Help

1. Sign in to Tableau Cloud or Tableau Server as an admin or someone who has been granted the "Set Permissions" capability.
2. From the left navigation pane, click **External Assets**. By default, the External Assets page shows a list of databases and files.
3. Select the check box next to the database whose permissions you want to lock, select **Actions > Permissions**, and then click the Table Permissions **Edit** link .
4. In the Table Permissions in Database dialog box, select **Locked** and click **Save**.
5. To unlock permissions, click **Edit** again, and select **Customized**.

Access lineage information

Catalog (and the Metadata API) can expose relationship and dependencies metadata, also referred to as *lineage*, among the Tableau content and external assets on Tableau Cloud or Tableau Server. Lineage shows three primary things:

- How items relate to each other, either directly or indirectly
- How many of those items relate to each other
- With the appropriate permissions, shows sensitive data about items in the lineage

Sensitive lineage data

In some cases, lineage can contain sensitive data, such as data quality warning messages, content or asset names, or related items and metadata.

By default, complete lineage information displays for all users while its sensitive data is blocked from specific users who don't have the appropriate View capabilities. The concept of blocking sensitive data is called obfuscation.

Obfuscation allows all metadata in the lineage to be visible while keeping its sensitive data blocked from specific users who don't have the appropriate View capabilities. This default enables workflows that rely on a complete impact analysis.

If obfuscating sensitive data in the lineage is not enough for your organization, certain parts of the lineage, including its sensitive data, can be filtered.

Filtering omits certain parts of the lineage (and lineage-related areas like data details) for specific users who don't have the appropriate **View** capabilities for its sensitive data. Because filtering omits parts of lineage, it prevents workflows that rely on a complete impact analysis.

To change how sensitive data is handled, do the following:

1. Sign in to Tableau Cloud or Tableau Server as an admin.
2. From the left navigation pane, click **Settings**.
3. On the General tab, under **Sensitive Lineage Information**, select the radio button that best handles lineage information for all users on your Tableau Cloud site or Tableau Server.

Additional notes about lineage

- **If you have the View capability on related assets**, you can see when and what assets and content are related to each other, and their sensitive metadata.

For example, you can see 1) the names, data quality warnings, and total number of related upstream databases and tables and 2) the combined number of sheets (visible and hidden) in the lineage of the downstream workbook of the asset you are evaluating.

- **If you *don't* have the View capability on related assets**, you can always see when assets relate to each other.

For example, you can see 1) whether related upstream databases and tables exist in the lineage and 2) the total number of databases or total number of tables that are related to the asset you are evaluating.

However, you can't see the metadata associated with those assets when you don't have the view capability for them. When metadata is blocked because of limited permissions, or the asset is in a Personal Space, you see **Permissions Required**.

External Assets / Opportunities

Opportunities

About

Hostname: login.salesforce.com Database Type: Salesforce

	Type	↑ Name	Workbooks
<input type="checkbox"/>	Table	Permissions Required	2
<input type="checkbox"/>	Table	Permissions Required	0
<input type="checkbox"/>	Table	Price	0

Aug 7, 2019, 10:23 AM

For more information about lineage see [Use Lineage for Impact Analysis](#).

Additional notes about tags discoverable through lineage data

In addition to Tableau content, external assets can also be tagged. Although tags are always visible, tagged items that you see through lineage data can either be obfuscated (default) or filtered as described earlier in this topic.

When tagged items are obfuscated:

- **If you have the View capability for tagged items**, you can see the tagged items and related tagged items, and all metadata.
- **If you don't have the View capability for tagged items:**
 - You can see the type of tagged and related tagged items but you can't see sensitive metadata about the items. For example, suppose you use a tag filter to see items with the tag "Noteworthy." Although you can see that there are database items tagged with "Noteworthy," you can't see the names of the tagged databases.

- You can see how many related tagged items there are. For example, suppose you do a tag query on “Noteworthy.” Your query returns five tagged databases.

When tagged items are filtered, the tagged and related tagged items you see are limited to only the items that you have the View capability for.

For more information about tags, see [Tagged Items](#) in the Tableau User Help.

Potential mismatch between asset results and content results

When Catalog shows lineage information, it provides information about Tableau content and external assets. Catalog lineage always shows the true count or result of associated items. However, in other areas of the site, you might see fewer items. This could be because of your **View** capabilities. Outside of Catalog, you see only the content that your permissions allow.

For example, suppose you're looking at the Superstore data source. The lineage for the Superstore data source shows how many upstream underlying tables the data source connects to and how many downstream workbooks rely on the data source. However, because you might not have permissions to see all of those downstream workbooks, the number of related workbooks in the Catalog lineage (actual total) might be greater than the number of workbooks in the **Connected Workbooks** tab (what you have permission to see).

There might be other reasons, unrelated to permissions, why you might see a mismatch between asset counts and content counts. For more information, see [Use Lineage for Impact Analysis](#).

Who can do this

The following information summarizes the types of users who can do the tasks described in this topic.

Tableau Cloud site or Tableau Server admin

Data Management	Capability	Requirements
Licensed	See assets and their metadata	None

Data Management	Capability	Requirements
	Edit assets and their metadata	None
	Change permission on assets and their metadata	None
	Grant users ability to see assets and their metadata	<p>Default: When “derived permissions” is on, your users can see metadata on external assets for the content that they own, or for the content that is published to a project that they are a project leader or project owner of.</p> <p>Ad-hoc: You can configure explicit View permissions on a specified external asset.</p>
	Grant users ability to edit assets and their metadata	You can configure explicit "write" or Overwrite permissions on a specified external asset (if not automatically granted because the user is a flow owner) .
	Grant users ability to change permissions on assets and their metadata	You can configure explicit "edit" or Set Permissions on a specified external asset (if not automatically granted because the user is a flow owner) .

Data Management	Capability	Requirements
Not licensed	See all assets and their metadata	Applies to Metadata API only
	Edit assets and their metadata	Requires Data Management
	Change permission on assets and their metadata	Requires Data Management
	Grant users ability to see assets and their metadata	Applies to Metadata API only: You can turn on derived permissions as described above. If “derived permissions” is on, your users can see metadata on external assets for the content that they own, or for the content that is published to a project that they are a project leader or project owner of.
	Grant users ability to edit assets and their metadata	Requires Data Management
	Grant users ability to change permissions on assets and their metadata	Requires Data Management

User with Creator or Explorer license

Data Management	Capability	Requirements
Licensed	See assets and their metadata	<p>Default: When "derived permissions" is enabled by your Tableau Cloud site admin or Tableau Server admin, you can see metadata on external assets for the content that you own, or for the content that is published to a project that you are a project leader or project owner of.</p> <p>Ad-hoc: You can see metadata on external assets that you have been granted explicit View permissions to.</p>
	Edit assets and their metadata	You can edit metadata on an external asset that you have been granted explicit "write" or Overwrite permissions to (if not automatically granted because the user is a flow owner).
	Change permissions on assets and their metadata	You can change permissions on an external asset that you have been granted explicit "edit" or Set Permissions to ((if not automatically granted

Data Management	Capability	Requirements
		because the user is a flow owner).
	Grant other users permissions to see assets and their metadata	You can change permissions on an external asset that you have been granted explicit "edit" or Set Permissions to ((if not automatically granted because the user is a flow owner).
Not licensed	See assets and their metadata	Applies to Metadata API only: If "derived permissions" is enabled by your Tableau Cloud site admin or Tableau Server admin, you can see metadata on external assets for the content that you own, or for the content that is published to a project that you are a project leader or project owner of.
	Edit assets and their metadata	Requires Data Management
	Change permissions on assets and their metadata	
	Grant other users permissions to see assets and their metadata	

Manage Data

You can connect to and manage the data you that you use in Tableau.

Tableau Server Data Sources

When your Tableau users want to share data connections they've defined, they can publish data sources to Tableau Server. When a data source is published to the server, other users can connect to it from their own workbooks, as they do other types of data. When the data in the Tableau data source is updated, all workbooks that connect to it pick up the changes.

Looking for Tableau Server on Linux? See [Tableau Server Data Sources](#).

A Tableau Server data source consists of metadata that describes the following:

- **The connection information:** Defines whether the data is in a live database or an extract, and which of that data to bring in to Tableau.
- **Customization and cleanup:** Includes information that facilitates efficient use of the data. For example, calculations, sets, groups, bins, parameters, custom field formatting, and so on.
- **Data access and refresh instructions:** Includes the location of the underlying database server (whether on-premises or in the cloud), network paths for file-based data, security information such as credentials or access tokens, and related information.

In addition to helping your users create data consistency and reliability, using Tableau data sources offers advantages to you as the administrator. Because multiple workbooks can connect to one data source, you can minimize data source proliferation and save on storage space and processing time. When someone downloads a workbook that connects to a Tableau data source that in turn has an extract connection, the extract stays on the server, reducing network traffic. Finally, if a connection requires a database driver, you need to install

and maintain the driver only on the server, instead of on each user's computer. If you use Tableau Cloud, all supported drivers are available to data sources published to your site.

Managing data sources

You can perform some or all management tasks on a data source if you have one of the following levels of access:

- Site or server administrator
- Project leader or owner of the project the data source is published to

Full project leader access is available only with some site roles. For information, see [Project-level administration](#).

- Data source owner

Unless you're a site or server administrator, you might not have access to all management tasks. For example, if the Permissions menu is not available, chances are that the project permissions are locked, which denies setting permissions on individual workbooks and data sources.

Tip: A best practice is to designate a person or team to manage all data sources published to a project or to the whole site, so that all data sources can be maintained under the same set of guidelines.

To perform the management tasks that you have access to, do the following:

1. Sign in to the site, and on the **Content** tab, select **Explore > Data sources**.
2. On a data source, select the **Actions (...)** menu.

- **New workbook or Download:** Create a new workbook in the browser environment that connects to this data source. Or download the data source to use locally.
- **Tag:** Add or remove keyword tags. Tags can contain a single word or multiple words, delimited by a comma.
- **Move:** Move a data source from one project to another. This requires specific settings on each project. For information, see Requirements for moving assets.
- **Permissions:** View or update permissions that specify which users or groups can connect to, modify, or download the data source. As mentioned at the beginning of this section, if this action is not available, the project permissions might be locked, and only the project leader or administrator can change permissions.
- **Change owner:** Making someone an owner gives them complete access to it.
- **Refresh extracts:** If a data source includes an extract, you can assign the extract to a refresh schedule.

For information, see [Refresh Data on a Schedule](#).

- **View the data source's revision history**
- **Delete:** Deleting a data source affects workbooks that connect to the data source. Before you delete a data source, ensure that there are no workbooks that connect to the data source or edit the workbooks to use another data source.

In addition, for data sources that are proxy connections, administrators can stay aware of how users authenticate to the database, and whether the appropriate drivers are installed. For information, see [Database Drivers and Data Security](#).

Restrictions

Published data sources often function as curated and trustworthy data sources. As such, there are restrictions on how they can be modified and used.

Aliases and calculations can't be edited.

- New aliases also can't be created. Fields can be duplicated and the copy can be aliased.
- New calculations can be created. Existing calculation can also be copied and the copy can be edited.

Relationships and joins can't be edited.

Published data sources cannot be used in joins or relationships.

- Use blends if you need to combine published data sources.

Extract Upgrade to .hyper Format

In Tableau version 2018, we introduced the `.hyper` format for Tableau extracts to replace the old `.tde` format. The `.hyper` format has been the standard format used by Tableau to create extracts since 2018, and the large majority of extracts are now `.hyper` files. Beginning in early 2023, Tableau is discontinuing support for the `.tde` format on Tableau Cloud and Tableau Public. For more details, see this [Tableau Community post](#).

Discontinuation of support for TDE extract files

Beginning in 2023, the `.tde` format for Tableau extracts is deprecated. This format was replaced by the `.hyper` format in 2018 but continued to be valid for uploaded files until March 2023.

- This change takes place for Tableau Cloud and Tableau Public as of March 2023.
- Beginning with version 2023.1.0 of Tableau Server, the uploading of `.tde` format files is disabled by default. A Server Administrator can change this behavior. For more information, see `features.Hyper_DisallowTDEPublishing`.

It is unusual to have existing `.tde` files because these were replaced by `.hyper` format files in 2018 and several common actions on the files automatically and permanently convert them to the supported `.hyper` format. For details see below.

Tasks that cause extract upgrade

There are three distinct ways a `.tde` extract can get upgraded to a `.hyper` extract: 1.) during an extract refresh (full or incremental), 2.) when appending data to an extract, and 3.) when an extract is upgraded manually using Tableau Desktop 2022.4. After an extract has been upgraded, the original `.tde` extract is automatically removed from Tableau Server if it's not being reference by other workbooks.

The followings tasks on Tableau Server automatically upgrades and converts a `.tde` extract to a `.hyper` extract:

- Manual extract refresh
- Scheduled extract refresh
- Automated refresh task that's performed through `tabcmd`
- Automated refresh task that's performed through the Extract Command-Line Utility
- Automated append data to an extract using `tabcmd`

- Automated append data to an extract using the Extract Command-Line Utility
- Encryption of a .tde extract. For more information, see [Extract Encryption at Rest](#).

Set the Site Time Zone for Extracts

The default time zone for extract-based data sources in a site is Coordinated Universal Time (UTC). Server administrators can set a different time zone.

To set the site time zone for extracts:

1. Sign in to Tableau as an administrator.
2. On the site you want to configure, click **Settings**.
3. In the **Site Time Zone for Extracts** section, select a time zone and then click **Save**.

In calculated fields, functions such as NOW() or TODAY() look at the time zone. For more information about Extracts, see [Extract Your Data](#) in the Tableau Desktop help.

The timezone setting, in addition to being used for extract-based data sources, also affects internal extracts. For example, when Tableau connects to file-based data sources like text files, an extract is automatically created internally. Similarly, this happens where Tableau uses an internal extract to integrate data from different sources.

Create Extracts on the Web

You can extract your data sources in the web (without using Tableau Desktop) to improve data source performance and support additional analytical functions. When you extract your data source, Tableau will copy the data from your remote data store to Tableau Server or Tableau Cloud. To learn more about the benefits of extracting your data, see [Extract Your Data](#). In the web, you can extract while in Web Authoring or while in Content Server.

Create extracts in Web Authoring

You can create extracts directly in web authoring with default extract settings.

Extract an Embedded Data Source in Web Authoring

To create an extract in web authoring:

Tip: It is recommended to finalize your data model before you create the extract. Extract creation may take a long time and any changes to your data model, such as adding new logical tables, will invalidate the extract.

1. Click the **Data Source** tab in the bottom left corner of the web authoring pane. For new workbooks, you will start in the **Data Source** tab.
2. In the top-right corner, change the connection type from **Live** to **Extract**.
3. Click **Create Extract**. You will see the **Creating Extract** dialog box.

Extract creation might take a long time and you can close your authoring session while the extract is being created. To ensure your extract creation is not lost, in the dialog box, click **Notify Me When Complete** to specify a location for the extracted workbook to be saved. If your extract succeeds, your workbook will be saved to the specified location and you will be

notified that you can continue your web authoring session. If your extract creation fails, you will be notified that the extract could not be created and you can restore your unsaved changes by reopening the original workbook in web authoring.

Define your Extract Settings

The image shows a dialog box titled "Extract Data" with a close button (X) in the top right corner. The dialog is divided into two main sections. The first section, "Specify how to store data in the extract", contains two radio buttons: "Logical Tables" (which is selected) and "Physical Tables". Below these is a text block stating "Store data using one table for each logical table. [Learn more](#)" and "Use this option if you need to use extract filters, aggregation, or other extract settings." The second section, "Specify how much data to extract", contains three settings: "Filters" set to "0" with an "Edit" link, "Aggregation" set to "No" with an "Edit" link, and "Number of Rows" set to "All rows" with an "Edit" link. At the bottom of the dialog are three buttons: "Save Settings", "Cancel", and "Create Extract".

Save Settings Cancel Create Extract

Optionally, configure one or more of the following options to tell Tableau how to store, define filters for, and limit the amount of data in your extract:

- **Decide how the extract data should be stored**

You can choose to have Tableau store the data in your extract using one of two structures (schemas): logical tables (denormalized schema) or physical tables (normalized schema). For more information about logical and physical tables, see [The Tableau Data Model](#).

The option you choose depends on what you need.

- **Logical Tables**

Stores data using one extract table for each logical table in the data source. Physical tables that define a logical table are merged and stored with that logical table. For example, if a data source was made of a single logical table, the data would be stored in a single table. If a data source was made of three logical tables (each containing multiple physical tables), the extract data would be stored in three tables—one for each logical table.

Select **Logical Tables** when you want to limit the amount of data in your extract with additional extract properties like extract filters, aggregation, Top N, or other features that require denormalized data. Also use when your data uses pass-through functions (RAWSQL). This is the default structure Tableau uses to store extract data. If you use this option when your extract contains joins, the joins are applied when the extract is created.

- **Physical Tables**

Stores data using one extract table for each physical table in the data source.

Select **Physical Tables** if your extract is comprised of tables combined with one or more equality joins and meets the conditions for using the Physical Tables option listed below. If you use this option, joins are performed at query time.

This option can potentially improve performance and help reduce the size of the extract file. For more information about how Tableau recommends you use the Physical Tables option, see [Tips for using the Physical Tables option](#) in the Tableau Desktop help. In some cases, you can also use this option as a work-around for row-level security. For more information about row-level security using Tableau, see [Restrict Access at the Data Row Level](#) in the Tableau Desktop help.

Conditions for using the Physical Tables option

To store your extract using the Physical Tables option, the data in your extract must meet all of the conditions listed below.

- All joins between physical tables are equality (=) joins
- Data types of the columns used for relationships or joins are identical
- No pass-through functions (RAWSQL) used
- No incremental refresh configured
- No extract filters configured
- No Top N or sampling configured

When the extract is stored as physical tables, you cannot append data to it. For logical tables, you can't append data to extracts that have more than one logical table.

Note: Both the Logical Tables and Physical Tables options only affect how the data in your extract is stored. The options do not affect how tables in your extract are displayed on the Data Source page.

- **Determine how much data to extract**

Click **Add** to define one or more filters to limit how much data gets extracted based on fields and their values.

- **Aggregate the data in the extract**

Select **Aggregate data for visible dimensions** to aggregate the measures using their default aggregation. Aggregating the data consolidates rows, can minimize the size of the extract file, and increase performance.

When you choose to aggregate the data, you can also select **Roll up dates** to a specified date level such as Year, Month, etc. The examples below show how the data will be extracted for each aggregation option you can choose.

Original data	<p>Each record is shown as a separate row. There are seven rows in your data.</p> <table><thead><tr><th></th><th>Date</th><th>Region</th><th>Sales</th></tr></thead><tbody><tr><td>1</td><td>1/1/2009</td><td>South</td><td>\$500</td></tr><tr><td>2</td><td>1/1/2009</td><td>West</td><td>\$200</td></tr><tr><td>3</td><td>1/1/2009</td><td>West</td><td>\$100</td></tr><tr><td>4</td><td>1/1/2009</td><td>East</td><td>\$300</td></tr><tr><td>5</td><td>1/2/2009</td><td>South</td><td>\$600</td></tr><tr><td>6</td><td>1/2/2009</td><td>South</td><td>\$400</td></tr><tr><td>7</td><td>1/2/2009</td><td>East</td><td>\$100</td></tr></tbody></table>		Date	Region	Sales	1	1/1/2009	South	\$500	2	1/1/2009	West	\$200	3	1/1/2009	West	\$100	4	1/1/2009	East	\$300	5	1/2/2009	South	\$600	6	1/2/2009	South	\$400	7	1/2/2009	East	\$100
	Date	Region	Sales

3	1/1/2009	West	\$300																														

- **Choose the rows to extract**

Select the number of rows you want to extract.

You can extract **All rows** or the **Top *N* rows**. Tableau first applies any filters and aggregation and then extracts the number of rows from the filtered and aggregated results. The number of rows options depend on the type of data source you are extracting from.

Notes:

- Not all data sources support sampling. Therefore, you might not see the **Sampling** option in the Extract Data dialog box.
- Any fields that you hide first in the Data Source page or on the sheet tab will be excluded from the extract.

Limitations

- You can't create extracts for embedded data sources that reference published data sources. As a workaround, create the extract directly on the published data source. For more information, see [Extract a Published Data Source on Content Server](#).
- You can't create extracts for file-based data sources. File-based data sources already have special performance features and adding extraction will have no performance benefit.
- This feature does not apply to bridge-based data sources in Tableau Cloud.

Create extracts in Content Server

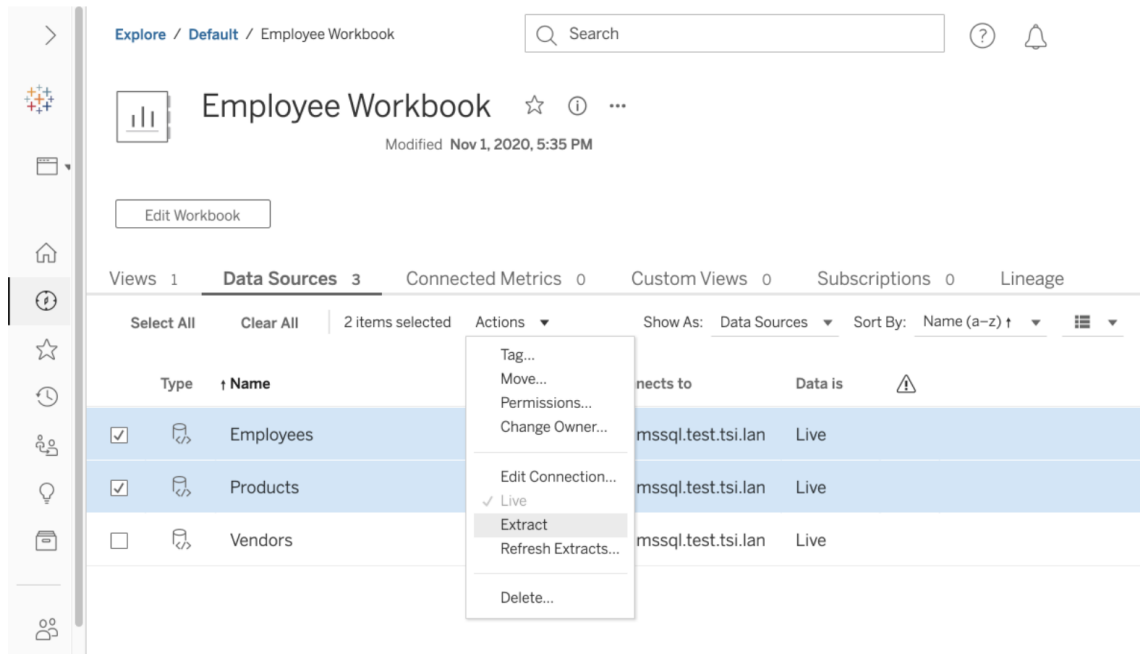

Extract a Published Data Source on Content Server

To extract a published data source:

1. Sign in as an administrator or as the owner of the data source.
2. On the Content tab, select **Explore > Data sources**.
3. Select a data source by clicking on the Data Source name.
4. At the top of the screen, under the Data Source name, select the drop-down menu that says **Live**.
5. Change the connection type from **Live** to **Extract**. If the extract encryption at rest feature is enabled on the site, select either **Encrypted** or **Unencrypted**.
6. If you see an error message about embedded credentials, embed your credentials in the data source. To do this, click **Edit Connection**. Select "Embedded password in connection" and then click **Save**.

Extract an Embedded Data Source on Content Server

To extract one or more data sources that are embedded in a published workbook:

1. Sign in as an administrator or as the owner of the data source.
2. Navigate to the published workbook.
3. Navigate to the Data Sources tab
4. Select one or more of the data sources.
5. Click the **Action** button.
6. Click **Extract**. If the extract encryption at rest feature is enabled on the site, select either **Encrypted** or **Unencrypted**.

Limitations

- Your connection credentials must be embedded in the data source.
- In the web, you can't specify extract settings like incremental refresh and extract filters.
- You can't create extracts for embedded data sources that reference published data sources. As a workaround, create the extract directly on the published data source.

- You can't create extracts for file-based data sources. File-based data sources already have special performance features and adding extraction will have no performance benefit.
- This feature does not apply to bridge-based data sources in Tableau Cloud.

Keep Extracted Data Fresh

After data is extracted, you can optionally set up an extract refresh schedule to keep the data fresh. For more information, see [Refresh Data on a Schedule](#).

Monitor and Manage Extracts

Server administrators can monitor extract creation on the **Background Tasks for Extracts** admin view. For more information, see [Background Tasks for Extracts](#).

Server administrators can manage extracts on the Jobs page. For more information, see [Managing Background Jobs in Tableau Server](#).

Extract creation jobs, like extract refresh jobs, have a maximum query limit before they timeout. This is to prevent jobs from running forever and using an unbounded amount of server resources. The extract query limit timeout can be configured by server admins using the TSM command line interface configuration setting `backgrounder.querylimit`. For more information, see [tsm configuration set Options](#).

Server administrators can manage web authoring. For more information, see [Set a Site's Web Authoring Access and Functions](#).

View Data Source Attributes

In the **Content** area of the Tableau Server web authoring environment, you can filter the view to show only data sources or connections and their attributes.

View data sources by name

To filter by data source name, under **Explore**, select **Data sources**.

Attributes in the data source name list include the following:

- **Type**—The icon next to the data source name indicates whether the data source is published as a live connection (🔌), an extract connection (📦), or is embedded in a workbook (📖).
 - Select the name of a published data source to open its data source page, with tabs for viewing connections and workbooks that connect to it.
 - Select the name of an embedded data source to open the workbook associated with it, as well as tabs for viewing other data it connects to.
- **Connects To**—Indicates the name of the database server or data file. This could be a database outside of Tableau Server, an extract, or a published data source.
- **Live or Last Extract**—This column tells you whether the connection to the data is live, or, if it is a connection to an extract, when the extract was last updated.

View a list of connections

To filter by connection type, in the **View** list, select **Connections**.

Connection attributes include:

- **Connects to**—Indicates the name of the database server or data file. This could be a database outside of Tableau Server, an extract, or a published data source.
- **Connection type**—Shows the type of data. **Tableau Server** indicates that the connection is to a data source published on the site. **Tableau Data Engine** means the data source has an extract stored on the Tableau data server.

Keep Data Fresh

You can manually refresh data, as well as schedule data refreshes.

Manage Refresh Tasks

Administrators can change the priority of scheduled extract refreshes relative to other server tasks, manually refresh extracts, or delete their schedules.

1. Sign in to the site that has the schedules you want to manage, and then click **Tasks**.
2. Select one or more scheduled extract refreshes.
3. From the **Actions** menu, do any of the following:
 - Select **Change Schedule**, and choose a new schedule from the list.
 - Select **Run Now** to refresh manually.

Note: If an extract does not have a scheduled refresh, you can refresh it on demand from the Data Connections page.

- Select **Change Priority**, and enter a number between 1 and 100 to move the extract up or down in the priority list.

- Select **Delete** to completely remove the schedule for the selected data sources.

See also

Enable Extract Refresh Scheduling and Failure Notification

Refresh Data on a Schedule

You can schedule refresh tasks for published extract data sources and published workbooks that connect to extracts. New schedules can be created by Tableau Server Administrators on the **Schedules** page. For more information, see [Create or Modify a Schedule](#).

For information on how to refresh flow outputs, see [Schedule a Flow Task](#).

1. When you're signed in to Tableau Server, select **Explore** from the left navigation pane, and then, depending on the type of content you want to refresh, select **All Workbooks** or **All Data Sources** from the drop-down menu.
2. Select the check box for the workbook or data source you want to refresh, and then select **Actions > Refresh Extracts**.

3. In the Refresh Extracts dialog, select **Schedule a Refresh**, and complete the following steps:

- Select the schedule you want.
- If available, specify whether you want a full or incremental refresh.

A full refresh is performed by default. Incremental refresh is available only if you configured for it in Tableau Desktop before publishing the extract. For more information, see [Refreshing Extracts](#) in the Tableau Help.

- Click **Schedule Refresh**.

Quick Start: Refresh Extracts on a Schedule

For published workbooks that connect to data extracts, you can set up the server to refresh the extracts on a recurring schedule, so all workbooks connected to them always show the most up-to-date data.

To schedule refreshes you need to have administrator or data owner permissions.

Note: This topic applies to extracts published to Tableau Server. For Tableau Cloud, how you refresh extracts depends on the underlying data they connect to. For more information, see [Keep Data Fresh](#).

1 Set up a schedule on the server

Sign in to the server, go to the **Schedules** page, and click **New Schedule**.

Schedules 4							
+ New Schedule		▼ 1 selected		▼ Actions			
↑ Name			Frequency	Task type	Tasks	Execution	Next run at
<input checked="" type="checkbox"/>	End of the month	...	Monthly	Extract Refresh	0	Parallel	Jul 31, 2016, 11:00 PM
<input type="checkbox"/>	Saturday night	...	Weekly	Extract Refresh	1	Parallel	Jul 16, 2016, 11:00 PM
<input type="checkbox"/>	Weekday early mornings	...	Weekly	Extract Refresh	1	Parallel	Jul 18, 2016, 4:00 AM
<input type="checkbox"/>	Weekday mornings	...	Weekly	Subscription		Parallel	Jul 18, 2016, 6:00 AM

Tableau provides a few refresh schedules. You create additional schedules you need.

2 Enable scheduled extract refreshes and failure emails

As a server or site administrator, you can enable schedules, as well as email notification when extract refreshes fail.

Select **Settings**, and then go to the **General** page.

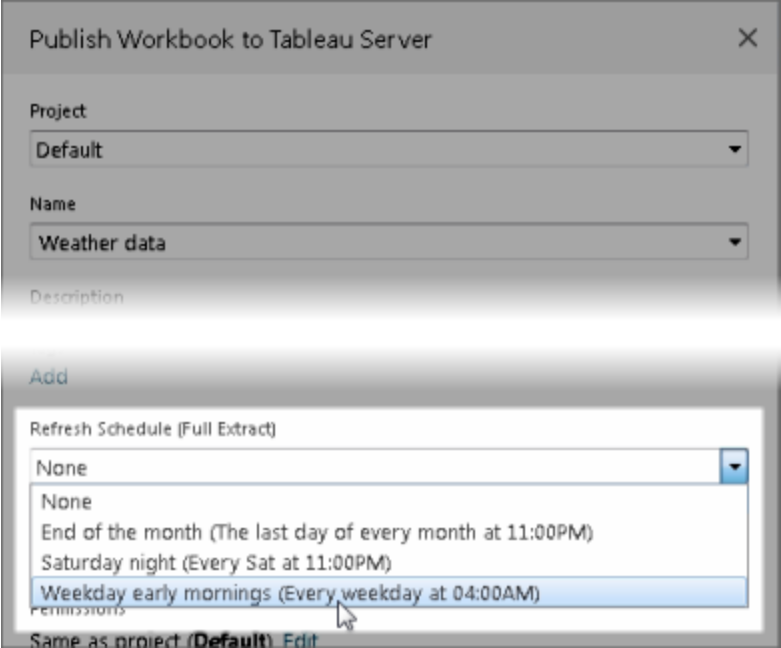

- Under Email Notification, select **Send email to data source and workbook owners when scheduled refreshes fail**.
- Under **Embedded Credentials**, select both check boxes to allow publishers to embed

credentials and schedule extract refreshes.

3 Publish a workbook with an extract

In Tableau Desktop, select **Server > Publish Workbook**. Sign in to the server if you're not already. In the **Publish Workbook to Tableau Server** dialog box, click **Schedules & Authentication**. Under **Extract Schedule**, select the schedule from the list.

If the original data requires authentication, you will also need to select how you want people to access it.

4 Monitor refresh performance

You can monitor scheduled tasks by viewing **Background Tasks for Extracts** on the **Status** page.

Server Status	
Traffic to Views	Usage and users for published views.
Traffic to Data Sources	Usage and users for published data sources.
Actions by All Users	Actions for all users.
Actions by Specific User	Actions for a specific user, including items used.
Actions by Recent Users	Recent actions by users, including last action time and idle time.
Background Tasks for Extracts	Completed and pending extract task details.

Automate Refresh Tasks

You can associate extract refresh tasks with schedules in Tableau Server to automate refreshing extracts. You can also automate extract refreshes using `tabcmd`, a command line utility that you can download for use with Tableau Server. In particular, you can use the `refreshextracts` command in combination with other commands in your own script. For example:

```
tabcmd login - http://mytabserver -u jsmith -p P@ssw0rd! refreshextracts --datasource salesq4
```

Note: When an extract refresh is performed on extracts created in Tableau 10.4 and earlier (that is, a `.tde` extract), the extract is upgraded to `.hyper` extract automatically. While there are many benefits of upgrading to a `.hyper` extract, your users won't be able open the extract with earlier versions of Tableau Desktop. For more information, see [Extract Upgrade to .hyper Format](#).

For information about downloading the `tabcmd` utility, see [tabcmd](#).

Handle Extract Refresh Alerts

When Tableau Server cannot complete a scheduled refresh, an alert appears to indicate that the refresh has failed. If a scheduled refresh fails five consecutive times, Tableau Server suspends the refresh. When a refresh is suspended, Tableau Server does not try to run it again until someone takes an action that attempts to correct the cause of the failure.

Note: The number of consecutive failures for a refresh is set to five by default, but can be changed by a Tableau Server administrator, using the `backgrounder.failure_threshold_for_run_prevention` option. For more information, see [tsm configuration set Options](#).

You will see the Alerts menu only if an extract refresh failed and you are:

- A system or site administrator
- The author of the workbook or data source that couldn't be refreshed
- The author of a workbook that connects to a data source that couldn't be refreshed

When you open the Alerts menu you can see more information about the refresh failure(s):

When a **Data source** is listed as **Embedded** it means that the data source definition (which includes things like the data source credentials or the database name) is embedded, or resides, within the workbook itself, originally created in Tableau Desktop.

When a data source name or workbook name is listed as the **Data source** (for example, **Data source: sales_data**), it means that the data source is a Tableau Server data source. The data source definition resides on Tableau Server.

In the Data pane on Tableau Desktop, you can determine whether the data source is on Tableau Server or is local. If the data source is on the server, a Tableau icon is displayed next to the data source name instead of a database icon :

Resolving Extract Refresh Problems

To resolve refresh issues, you can take any of these actions, based on the cause indicated in the alert:

- **Errors related to access token validation or user credentials**

You can resolve some extract refresh problems by clicking the **Connection Details** in the alert. Select the check box next to the problematic data source, click **Actions > Edit Connection**, and then enter the missing information. Click **Save** when you're done. After you update the connection information, Tableau Server restarts the refresh schedule.

If you originally embedded the credentials or other data connection information when you published the workbook or data source from Tableau Desktop, you can also republish the workbook or data source. As part of the publishing process, you can choose to set a new refresh schedule. If you don't choose a new schedule, Tableau Server restarts the existing schedule.

- **Errors that indicate the database was unreachable**

Confirm that the database is online and that you can sign in to access the data. You can use the **Try again** link in the alert to restart the refresh schedule.

- **Errors when using user filters or impersonation**

See the [Tableau Knowledge Base](#).

If the problem cannot be corrected by editing the data connection, you will need to resolve it in Tableau Desktop and republish the workbook.

Tip: Administrators can edit data connections at any time on the **Data Connections** page, accessible from each site by clicking the **Content** tab and Data Connections

Automatically Suspend Extract Refreshes for Inactive Workbooks and Data Sources

To save resources you can automatically suspend extract refresh tasks for inactive workbooks and published data sources. This feature applies to full extract refreshes that occur more frequently than once a week. Incremental refreshes and those that occur less frequently than weekly are not impacted.

Note: Support for automatic suspension of extract refreshes for data sources is available beginning in Tableau Server version 2023.3.

Note: Support for automatic suspension of extract refreshes for data sources is available beginning in the Tableau Cloud July 2023 release.

For a workbook, if any of the following events occur, the workbook's inactivity countdown timer is reset:

- Viewing the workbook sheets
- Having any data-driven alert or subscription set-up on the workbook
- Downloading the workbook
- Moving the workbook's location or changing the owner

For a published data source, any event which fetches the data from the data source will cause its inactivity countdown timer to be reset. These include:

- Loading a workbook view that is connected to the data source
- Visiting the data source's Ask Data page
- Tableau Desktop connecting to the data source

Configure the feature

1. Sign in to Tableau Server as a server administrator.
2. Go to the General tab of the Settings page for the site:
 - If you have a single site, at the top the browser window, click **Settings** and **General**.
 - If you have multiple sites, select the site you want to configure and click **Settings** and **General**.
3. On the **General** page, do the following:
 - Under **Automatically Suspend Extract Refresh Tasks**, select the **Automatically suspend extract refresh tasks for inactive workbooks and data-sources** check box.
 - Specify the number of days, from 7 through 100, that a workbook should be inactive before extract refresh tasks are suspended. The default is 32 days.
 - Click **Save**.

Notifications

An email notification is sent three days before the extract refresh schedule is suspended.

Another email notification is sent when the extract refresh schedule is suspended.

Resume suspended extract refreshes

Suspended extract refreshes won't automatically resume if someone uses the workbook. It must be done manually by a server or site administrator.

To view and resume extract refreshes that were suspended:

1. Sign in to the site as an administrator and click **Tasks**.
2. Click the **Extract Refreshes** tab.
3. Select one or more items.
4. From the **Actions** menu, select **Resume**.

Edit Connections on Tableau Server

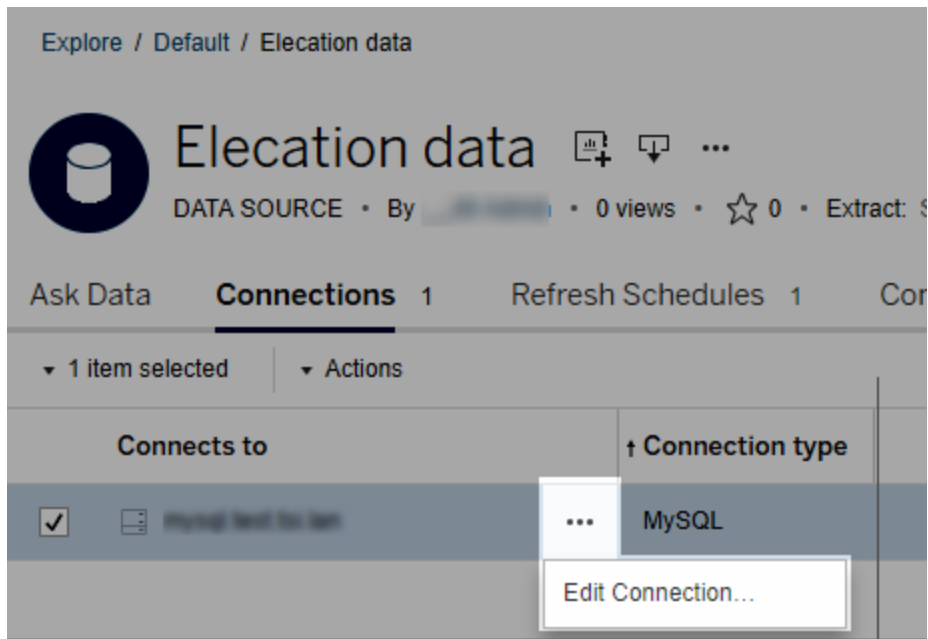

Administrators and data source owners can manage the information that describes how a published data source connects to the underlying data. This information includes the database server name or address, the server port, the database user name, and whether or not the password is embedded in the connection.

Note: Ability to edit connections is determined primarily by your site role, rather than by your permissions on the data source. To edit connections, your site role must be **Server Administrator**, **Site Administrator**, or **Creator**. If your site role is **Creator**, you also must be the data source owner.

1. Sign in to the site that has the data sources you want to modify, and on the **Content** tab, select **Explore > Data sources**.
2. Select the name of the data source with the connection you want to update.

Display filters to search for the data source or narrow the scope of the data source list. The values you type into the **Server name** and **Database username** fields are treated as regular expressions.

3. In the **Connections** view, select the **Actions (...)** menu for the data source, and then select **Edit Connection**.

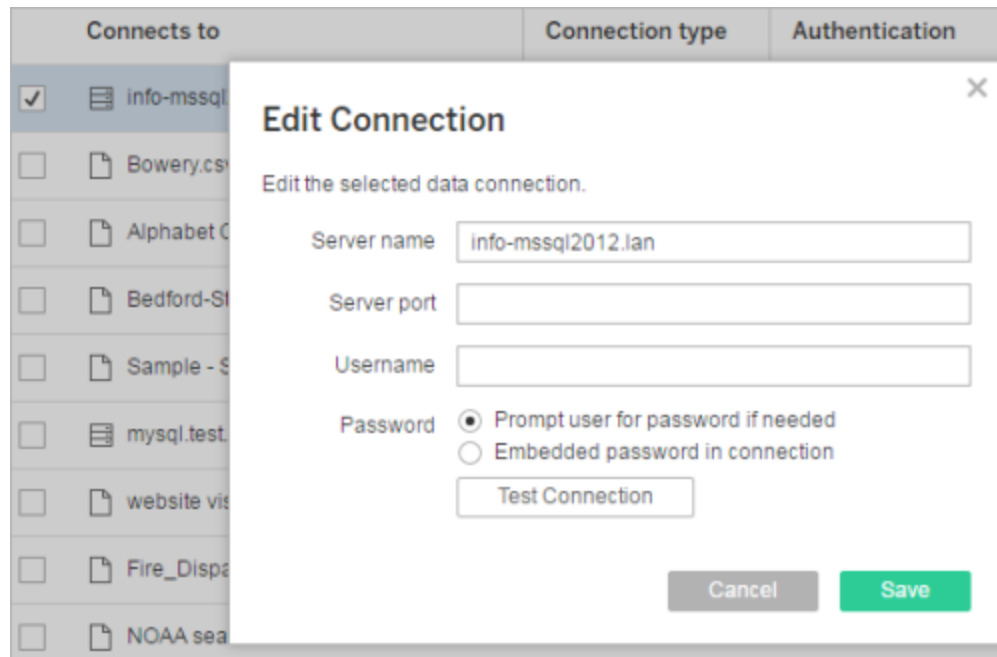

To edit multiple data sources, select the data sources you want to edit, then click the **Actions** menu and **Edit Connection**.

4. Update the connection information.

For **Server name**, if you want to use an IP address, make sure the database or its driver supports that type of connection. If it doesn't, enter the database server name.

See also Authentication types for Google, Salesforce, and WDC data later in this topic.

Note: The **Test Connection** button is disabled in versions 2021.4 and later when **Prompt user for password if needed** is selected.

5. Click **Save**.
6. Refresh the browser page for your changes to take effect.

Authentication types for Google, Salesforce, and WDC data

Google BigQuery, Google Analytics, Salesforce.com, and many web data connector (WDC) connections use the OAuth authentication standard, which uses secure access tokens instead of “raw” user name and password credentials. With OAuth, database credentials do not need to be stored in Tableau, and all users connect through this access token, including Tableau Desktop users who want to create or edit workbooks that connect to the data source.

The following sections describe Google and Salesforce connection options. Web data connector options vary, but all involve signing in through the provider’s web-based sign-in form to establish the access token.

Google authentication options

When you edit Google BigQuery or Google Analytics connections, select either of the following options in the **Edit Connection** dialog box:

- Select **Embed Google BigQuery (or Google Analytics) credentials in the connection** to authenticate through a designated account, and then select an existing account from the list or select **authenticate account now...** to add a new one.

When you add a new account, the Google sign-in page appears. After you provide your database credentials, Google prompts you to confirm Tableau access to the data. When you click **Accept**, Google returns an access token to use for connecting to the data.

Note: If you create extracts of your Google data source, select this first option, so that you can schedule refresh tasks.

- Select **Prompt user for Google BigQuery/Analytics credentials** to require users to connect through their own individual access tokens or sign in each time they connect.

Salesforce.com authentication options

Note: This applies only if Tableau Server is configured to use saved credentials for Salesforce with OAuth. If the server is not configured for this, use the standard process above for modifying connections. For more information about configuring Tableau Server to use saved credentials with OAuth, see [Change Salesforce.com OAuth to Saved Credentials](#).

When you edit Salesforce.com connections, you can select any of the following options in the **Edit Connection** dialog box:

- Select **Embedded Salesforce username and password in the connection** to use a traditional authentication method.

- Select **Embedded Salesforce credentials in the connection** to use an OAuth connection and schedule refresh tasks, and then select an existing account from the list or click **Add a Salesforce Account** to add a new one.

When you add a new account, the Salesforce.com sign-in page appears. After you provide your database credentials, Salesforce.com prompts you to confirm Tableau access to the data. When you allow Tableau access, Salesforce.com creates an access token through which it connects to the data.

Edit Connection

Edit the selected data connection.

Authentication

☒ Embedded Salesforce username and password in the connection

Username

Password

☐ Embedded Salesforce credentials in the connection

☐ No Salesforce authentication

Use this option if you do not need to schedule data extract refreshes

Test Connection

Cancel Save

- Select **No Salesforce authentication** to require users to sign in to Salesforce.com each time they connect. (This option does not allow scheduled extract refreshes.)

Monitor progress

When you save your changes in the **Edit Connection** dialog box, the dialog displays the progress. If you close the dialog box, the modifications continue to run in the background until completed. Tableau Server will make as many changes as possible. Any failures will be skipped, but they will not impede other changes. For example, if you try to change the server name and add a password to several connections, the server names will be changed, and the passwords on workbooks will be changed. However, because you cannot add a password to a data source, the passwords for the data sources will not be changed.

For information about checking the progress of these tasks, see [Background Tasks for Extracts](#).

Cube Data Sources

Cube (multidimensional) data sources have certain characteristics that make them unique in Tableau.

Cube data sources do not support pass-through connections. This means that when a cube data source is published, you cannot make a connection from Tableau Server using the data source. It also means you cannot create a workbook using the data source in Tableau Server.

Publishing a cube data source to Tableau Server gives you the ability to store the data source on the server. However, to use the data source, you must download the data source to Tableau Desktop and use it locally. To download a published data source you need:

- The **Download/Save As** permission for the data source. For more information, see [Permissions](#).
- Correct drivers installed and ports opened on computer running Tableau Desktop.

For information about using cube data sources with Tableau Desktop, see [Cube Data Sources](#).

Web Data Connectors in Tableau Server

Web data connectors (WDCs) are web pages that provide a data connection that is accessible over HTTP for data sources that don't already have a connector in Tableau. WDCs allow users to connect to almost any data that is accessible over the web and to create extracts for their workbooks. Data sources for a WDC can include internal web services, JSON data, REST APIs, and other sources that are available over HTTP or HTTPS. Users can create their own WDC or use connectors that were created by others.

For information about how to use a WDC in Tableau Desktop, see [Web Data Connector](#) in the Tableau Desktop documentation.

For information about how to create a WDC, see the [Web Data Connector documentation](#) on Github.

Before you run connectors on Tableau Server

As a security measure, Tableau Server won't run WDCs unless you approve the connector, as explained in this topic.

Note: You must be a server administrator to approve WDCs for use on Tableau Server.

WDCs require your approval because they contain executable code and typically make requests to third-party websites. Before a user can use a WDC with Tableau Server, you must add the domain and port used by the connector to a safe list and also include the domains that a connector can send requests to and receive requests from on a secondary safe list. Before you do this, we recommend that you vet and test the connector so that you know what the connector does and what sites it connects to. For more information, see [Testing and Vetting Web Data Connectors](#).

When you add a connector to the safe lists, you configure Tableau Server to allow connections to a particular URL where the connector is hosted and from a URL which the connector can query. This is the only way to allow Tableau Server to run WDCs. The connectors

can then be hosted on a server inside your organization's firewall or on an external domain. Importing WDCs is not supported for Tableau Server.

Manage connectors in a safe list

To add a WDC to the safe list, use the `tsm data-access web-data-connectors add` command. This command and the related commands described below let you perform the following tasks:

- Add WDCs to the safe list and secondary safe list.
- Allow or disallow all WDCs, or WDC refreshes.
- Remove one or more connectors from the safe list.
- List all WDCs on the safe list and secondary safe list.

Updating WDC safe lists requires a server restart

After running any commands that make changes to WDCs, you need to apply your pending changes using the `tsm pending-changes apply` command.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Add connectors to the safe list and secondary safe list

To add a connector to the safe list and secondary safe list, use the `tsm data-access web-data-connectors add` command, providing the name, safe list URL, and secondary safe list URLs. You can also manage WDCs using the web-data-connector-settings Entity. After running this command, you need to apply your pending changes using the `tsm pending-changes apply` command. A prompt warns you that the command will restart Tableau Server. If

Tableau Server is currently running it is restarted, and if it is stopped it is left in a stopped state with no restart.

```

```

Notes on formatting:

- Be sure to use straight quotes (" and '), not curly or "smart" quotes, around the name of the WDC. Use double quotes (") if the name contains a space.
- For many WDCs, the port specified for the `--url` option is 443 or 80, but you can check the value for your connector by looking at the data source details on Tableau Server. You must specify the port number as part of the URL if the WDC is using SSL (HTTPS). For example, to use the default port for HTTPS, the URL might look like the following: `https://example.com:443/WDC/`.

- A URL or comma-delimited list of URLs must be specified for the `--secondary` option, which indicates the domains that provide the libraries and sources that the WDC needs to access. This option cannot be omitted or left empty unless the WDC does not use any secondary domains. If you don't know whether the WDC uses secondary domains, or what the secondary domains are, you might need to contact the developer of the WDC. You can also choose to use `http://.*` and `https://.*` wildcard URLs to allow all domains. However, we strongly recommend that you use more specific URLs to increase security.
- To add an entire domain to the secondary safe list, end the domain URL with a wildcard expression. Use `.*` as the wildcard to indicate the entire domain, as in the following example: `https://example.com/.*`.

Allow or disallow WDCs or WDC extract refreshes

To allow or disallow WDCs, or WDC extract refreshes, use the `tsm data-access web-data-connectors allow` command with the `-t` or `-r` options. By default, WDCs and WDC extract refreshes are allowed. If you change this setting, you need to run the `tsm pending-changes apply` command. For more information about the command and the command options, see `tsm data-access web-data-connectors allow`.

Remove one or more WDCs from the safe list

To remove one or more WDCs from the safe list, use the `tsm data-access web-data-connectors delete` command. If you change this setting, you need to run the `tsm pending-changes apply` command. For more information, see `tsm data-access web-data-connectors delete`.

List all WDCs on the safe list

To list all WDCs on the safe list, use the `tsm data-access web-data-connectors list` command. For more information, see: `tsm data-access web-data-connectors list`.

Refresh the extract for a connector

When a user creates a workbook that uses a WDC, Tableau Server creates an extract from the data returned by the connector. If the user then publishes the workbook, the publish process sends the workbook and the data extract to the server.

Tableau can refresh an extract that was created by a WDC, the same as it can refresh any extract. If the connector requires credentials to sign in to the web-based data source, you need to ensure that the credentials are embedded with the data source, and that the WDC is on the safe list for the server. Tableau Server cannot refresh the extract if the connector requires credentials and they are not embedded with the data source. This is because the refresh can occur on a schedule or in some other background context, and the server cannot prompt for credentials.

Currently, there is no way to re-authenticate a data source from Tableau Server directly. If the data source has credentials that expire, or was published without embedding the credentials, the workbook and data extract need to be published again with the new embedded credentials.

If the background process that performs the refresh operation fails, it creates an alert and a log entry that indicates this issue. Users will be able to see that the timestamp on the extract does not change.

To disable refresh for all WDCs, use the `tsm data-access web-data-connectors allow -r false` command.

Troubleshooting

If the server experiences problems with adding connectors to the safe list, you can examine the log files. Be sure to check the log files on both the initial server node and on the other nodes that are running the gateway process. For more information about log files, Tableau Server Logs and Log File Locations.

If the issue is that Tableau Server will not refresh an extract that was created by a WDC, make sure that the `webdataconnector.refresh.enabled` configuration setting has been set

to `true`. If it is set to `false`, run the following command to allow extract refreshes for all WDCs on the server:

```
tsm data-access web-data-connectors allow -r true
```

Note: The safe list is the only way of allowing Tableau Server to run web data connectors. Importing web data connectors was deprecated starting with version 10.5.

Testing and Vetting Web Data Connectors

Web Data Connectors (WDCs) contain JavaScript that typically connects to data on another site. Because of this, you should test and vet web data connectors before users use them as data sources for a workbook, and before you use them with Tableau Server.

This topic includes some suggestions for testing and vetting web data connectors.

Examine the source

The code in a web data connector is in JavaScript, so you can open the file (and any external files that the connector uses) and examine the source code.

Many connectors reference external JavaScript libraries, such as the jQuery library or API libraries for third parties. Validate that the URL for external libraries points to a trusted location for the library. For example, if the connector references the jQuery library, make sure that the library is on a site that is considered standard and safe. If it is practical for you to change the source code of the connector, use HTTPS protocol (`https://`) to reference external libraries (if the source site supports HTTPS) to help verify the site's authenticity.

To the extent possible, make sure you understand what the code is doing. In particular, try to understand how the code is constructing requests to external sites, and what information is being sent in the request.

Note: Experienced JavaScript programmers often compress (minify) their code to reduce the size of the code for download. Dense blocks of code that use cryptic function and variable names are not uncommon. While this can make it more difficult to examine the code, it is not a sign that the code was written to be deliberately difficult to understand.

Test the web data connector in an isolated environment

If possible, test the web data connector in an environment that is isolated from your production environment and from user computers. For example, add a web data connector to a safe list on a test computer or virtual machine that's running a version of Tableau Server that is not used for production.

Monitor the traffic created by the web data connector

When you test a web data connector, use a tool like [Fiddler](#), [Charles HTTP proxy](#), or [Wire-shark](#) to examine the requests and responses that the connector makes. Make sure that you understand what sites the connector makes requests to and what content the connector is requesting. Similarly, examine the responses and their content to be sure that the connector is not reading data or code that is not directly related to the connector's purpose.

Test the performance and resource usage of the web data connector

When you test a web data connector, use tools to monitor its CPU and memory usage. Remember that the web data connector will run on Tableau Server, which is an environment in which many processes are already running. You want to make sure that when the connector fetches data, the connector does not have an undue impact on server performance.

Check whether the connector writes to disk. If it does, check how much disk space it occupies, and examine the output to make sure you understand what it's writing and why.

Enable Tableau Catalog

Tableau Catalog discovers and indexes all of the content on your Tableau Cloud site or Tableau Server, including workbooks, data sources, sheets, metrics, and flows. Indexing is used to gather information about the content, or metadata, about the schema and lineage of the content. Then from the metadata, Catalog identifies all of the databases, files, and tables used by the content on your Tableau Cloud site or Tableau Server.

Catalog is available with the Data Management license. For more information, see [About Data Management](#).

In addition to Catalog, metadata about your content can also be accessed from both the [Tableau Metadata API](#) and the Tableau REST API using [Metadata Methods](#).

Before enabling Catalog

As a Tableau Server admin, there are a few things that you need to consider before and while enabling Catalog to ensure optimal performance of Catalog in your Tableau Server environment.

Required versions

Before enabling Catalog, make sure you're running *one* of the following versions of Tableau Server:

- At least Tableau Server 2019.3.4 or later
- At least Tableau Server 2019.4.2 or later
- At least Tableau Server 2020.1.0 or later
- At least Tableau Server 2020.2.15 or later
- Tableau Server 2020.3 and later

For more information about why these versions are required, see the [Tableau Knowledge Base](#).

What to expect when enabling Catalog

When Catalog is enabled, the content that already exists on your Tableau Server is immediately indexed.

Initial ingestion

The indexing process is comprised of two primary components, one of which is called initial ingestion. Initial ingestion can be broken down into two additional components:

- Content backfill
- Lineage backfill

The status of content backfill and lineage backfill are important to note later on when monitoring progress and validating that Catalog has been successfully turned on and is running in your Tableau Server environment.

Initial ingestion speed

The time it takes Catalog to index the content for the first time depends on a couple of factors:

- **Amount of content on Tableau Server:** The amount of content is measured by the total number of workbooks, metrics, published data sources, and flows published to Tableau Server. For more information, see [Disk space to store metadata](#).
- **Number of non-interactive microservice containers:** Catalog uses the non-interactive microservice containers to index all the content on Tableau Server. For more information, see [Memory for non-interactive microservice containers](#).

Understanding the factors that impact initial ingestion can help you gauge how long it might take to enable and run Catalog in your environment.

Disk space to store metadata

During initial ingestion, metadata is generated and stored in the Tableau Server repository ("relationship" PostgreSQL database). The amount of disk space needed to store the

metadata is roughly up to half of the disk space currently used by the repository ("workgroup" PostgreSQL database).

For example, suppose the repository uses 50 GB of disk space prior to enabling Catalog, the repository can use up to 75 GB of disk space after enabling Catalog.

Memory for non-interactive microservice containers

Initial ingestion runs inside of the non-interactive microservice container. The non-interactive microservice container is one of two [Tableau Server microservice container](#) processes. By default, one instance of the non-interactive microservice container process is added to every node that has a background process installed.

By default, initial ingestion on a single instance of the non-interactive microservice container can use up to 4 GB of memory on the background node. If the amount of content on Tableau Server exceeds 10,000, a non-interactive microservice container process may require up to 16 GB of memory on the background node. Therefore, when enabling Catalog, ensure that every background node has the available capacity to support each non-interactive microservice container during the initial ingestion process. If capacity needs to be increased, you must update the JVM heap size for non-interactive microservice containers to allocate up to 16 GB of memory on the background nodes. For more information, see [non-interactive.vmopts](#).

If you are planning to add more non-interactive microservice containers to decrease the time of initial ingestion, first determine how many total containers are needed (using [Step 2: Estimate how long initial ingestion will take](#), below) and then verify if your Tableau Server environment is configured with enough capacity to support *all* non-interactive microservice containers.

Depending on how your Tableau Server environment is already configured, you might not be able to add all the additional non-interactive microservice containers that you need to decrease initial ingestion time.

Best practices for enabling Catalog

Because the speed of initial ingestion and requirements are unique to each Tableau Server environment, Tableau recommends that when you enable Catalog you do one or more of the following:

- Make sure there is enough disk space that the Tableau Server repository can use to support the additional metadata that initial ingestion will generate and store. As a general rule, the repository will need an additional 50% of disk space currently used by the repository. For more information about Tableau Server disk usage, see [Server Disk Space](#).
- Depending on the amount of content on Tableau Server, make sure each background node has at least 4-16 GB of available memory for each instance of a non-interactive microservice container during initial ingestion.
- Perform the process over the weekend to allow initial ingestion to complete before your users start using Catalog capabilities.
- Perform the process in a test environment with production content first. This is because the type of content that needs to be ingested can play a significant role on ingestion speed.

Summary of steps to enable Catalog

The following steps summarize the process to turn on and run Catalog on Tableau Server. The steps must be performed sequentially.

1. [Determine the amount of content on Tableau Server](#)
2. [Estimate how long initial ingestion will take](#)
3. [Decrease the time of initial ingestion](#)
4. [Activate the Data Management license](#)
5. [Turn off Catalog capabilities](#)
6. [Run the `tsm maintenance metadata-services` command](#)
7. [Monitor initial ingestion progress and validate its status](#)

8. [Configure SMTP](#)
9. [Turn on Catalog capabilities](#)

Note: Because indexing metadata about Tableau content on Tableau Server is powered by the Metadata API, enabling the Metadata API is required to run and use Catalog.

Enable Catalog

Step 1: Determine the amount of content on Tableau Server

To determine the amount of content on Tableau Server, do the following:

1. Sign in to Tableau Server using your admin credentials.
2. Go to the **Explore** page.
3. Click the Top-Level Project drop-down menu and add the numbers next to **All Workbooks**, **All Metrics**, **All Data Sources**, and **All Flows** together. This is the total amount of content on Tableau Server.

Step 2: Estimate how long initial ingestion will take

To estimate the time it will take Catalog to ingest content on Tableau Server for the first time (initial ingestion), compare *your* Tableau Server setup to a *baseline* Tableau Server setup.

For a Tableau Server with the following setup, initial ingestion could take about 6 hours to complete.

Components	Baseline values
Content	17,000 workbooks, metrics, published data sources, and flows
Non-interactive microservice containers	10
Ingestion	~6 hours

If you have roughly *half* the content in your Tableau Server environment, initial ingestion might take half the time to complete.

For example: 8,500 (workbooks, metrics, published data sources, and flows) + 10 non-interactive microservice containers = ~3 hours (initial ingestion)

If you have roughly *double* the content in your Tableau Server environment, initial ingestion might take double the time to complete.

For example: 34,000 (workbooks, metrics, published data sources, and flows) + 10 non-interactive microservice containers = ~12 hours (initial ingestion)

Step 3: Decrease the time of initial ingestion

As a general rule, the time it takes for Catalog to perform initial ingestion is correlated to the number of non-interactive microservice containers. To help decrease the time of initial ingestion, you can increase the number of non-interactive microservice containers.

Increase the number of non-interactive microservice containers

By default, one non-interactive microservice container is added to every node that has a backgrounder. To help decrease the time of initial ingestion, Tableau recommends that you increase the number of non-interactive microservice containers using the `tsm topology set-process` command.

1. Open a command prompt as an admin on the initial node (where TSM is installed) in the cluster.
2. Run the command: `tsm topology set-process --count <process_count> --node <node_ID> --process <process_name>`

For example, to increase the non-interactive microservice containers on the initial node to 4 containers, run the following command:

```
tsm topology set-process --count 4 --node node1 --process non-interactive
```

For more information about running the command and its global options, see [tsm topology](#).

Important: Before increasing the number of non-interactive microservice containers, review the following:

- The recommendation for increasing non-interactive microservice containers is for the total number of non-interactive microservice containers, not total non-interactive microservice containers per node. For example, suppose you have 4 nodes but you want to increase the number of non-interactive microservice containers to 8. The `--count` value you use in the `tsm` command is 2.
- For each non-interactive microservice container added, 4 GB of additional memory will be used on the node and load will be added to the Tableau Server repository (PostgreSQL database).
 - Tableau recommends that you incrementally increase non-interactive microservice containers by no more than 2 at a time while closely monitoring your Tableau Server environment to avoid issues with CPU utilization of the Tableau Server repository (PostgreSQL database).
 - Be aware that when too many non-interactive microservice containers are added, CPU utilization of the PostgreSQL database might spike and failover. Symptoms to watch for include `SQLException` errors in the `vizportal` logs. For more information, see [Repository Failover](#) topic.

Step 4: Activate the Data Management license

(Requires Data Management)

If not already done, you can activate Data Management. For more information, see [License Data Management](#).

Step 5 (optional): Turn off Catalog capabilities for each site

(Requires Data Management)

As part of Data Management activation, Catalog capabilities are turned on by default. Because of the indexing process and the estimated time it takes to complete, consider temporarily turning off Catalog capabilities for each site so that Tableau Server users can't access Catalog capabilities until Catalog is ready and able to provide complete and accurate results.

1. Sign in to Tableau Server using your admin credentials.
2. From the left navigation pane, click **Settings**.
3. On the General tab, under Tableau Catalog, clear the **Turn on Tableau Catalog** check box.
4. Repeat steps 2-3 for each site on your Tableau Server.

Step 6: Run the `tsm maintenance metadata-services` command

Run the `tsm maintenance metadata-services` command to enable the Tableau Metadata API. Running the command begins initial ingestion. If your Tableau Server is licensed with Data Management, running the command also turns on Catalog capabilities (if it wasn't turned off earlier).

1. Open a command prompt as an admin on the initial node (where TSM is installed) in the cluster.
2. Run the command: `tsm maintenance metadata-services enable`

For more information about running the `tsm` command, see [tsm maintenance](#).

Notes: When running this command, keep the following points in mind:

- This command stops and starts some services used by Tableau Server, which causes certain functionality, such as the Recommendations capability, to be temporarily unavailable.

- A new index of metadata is created at this time. Running this command any subsequent times will create and replace the previous index.

Step 7: Monitor initial ingestion progress and validate its status

Running the tsm command above starts the initial ingestion process. To ensure that the initial ingestion process is going smoothly, you can monitor its progress using the Backfill API. For more information, see [Get Initial Ingestion Status](#).

Step 8: Configure SMTP Setup

If not already set up for Tableau Server, configure SMTP Setup. SMTP supports sending email to owners who need to be contacted about changes to data. For more information about configuring SMTP, see [Configure SMTP Setup](#).

Step 9 (optional): Turn on Catalog capabilities for each site

(Requires Data Management)

If you turned off Catalog capabilities before enabling Catalog in one of the procedures above, you must turn on Catalog to make its capabilities accessible to your users.

1. Sign in to Tableau Server using your admin credentials.
2. From the left navigation pane, click **Settings**.
3. On the General tab, under Tableau Catalog, select the **Turn on Tableau Catalog** check box.
4. Repeat steps 2-3 for each site on your Tableau Server.

Troubleshoot Catalog

You or your users might encounter one of the following issues when using Catalog.

Timeout limit and node limit exceeded messages

To ensure that Catalog tasks that have to return a large number of results don't take up all Tableau Server system resources, Catalog implements both timeout and node limits.

- **Timeout limit**

When tasks in Catalog reach the timeout limit, you and your users see the following message:

“Showing partial results, Request time limit exceeded. Try again later.” or TIME_LIMIT_EXCEEDED

To resolve this issue, as a Tableau Server admin, you can increase the timeout limit using the `tsm configuration set -k metadata.query.limits.time` command. For more information, see the [tsm configuration](#) and [tsm configuration set Options](#) topics.

Important: Increasing the timeout limit can utilize more CPU for longer, which can affect the performance of other processes on Tableau Server.

- **Node limit**

When tasks in Catalog reach the node limit, you and your users see the following message:

NODE_LIMIT_EXCEEDED

To resolve this issue, as a Tableau Server admin, you can increase the node limit using the `tsm configuration set -k metadata.query.limits.count` command. For more information, see the [tsm configuration](#) and [tsm configuration set Options](#) topics.

Important: Increasing the timeout limit can affect system memory.

Missing content

- If you suspect, after initial ingestion, content is missing from Catalog, you can use the Eventing API to help troubleshoot. Eventing handles indexing content on Tableau Server after initial ingestion. For more information, see [Get Eventing Status](#).

- When the connection between an embedded external asset and its downstream Tableau content is removed, it remains in Catalog (or the Tableau Metadata API) until it's automatically deleted by a backgrounder process that runs everyday at 22:00:00 UTC (coordinated universal time). For example, suppose a workbook, initially published with an embedded text file A, is republished with an embedded text file B. File A remains visible (or query-able) as an external asset until the backgrounder processes is able to delete it.

You can disable this backgrounder process from running if you do not want to remove these types of external assets or if you believe that it takes up system resources that you don't want to dedicate to this process. Alternatively, you can adjust the number of external embedded assets that are deleted. For more information, see `features.DeleteOrphanedEmbeddedDatabaseAsset` and `databaseservice.max_database_deletes_per_run`.

You can monitor this process in one of two ways:

- Filter on the **One-time job re-canonicalize existing database/table assets after a canonicalization logic change** task type in the [Background Tasks for Non Extracts](#) admin view.
- Refer to the **Finished removal of orphaned embedded databases or database_service_canonicalization_change** events in the [Tableau Server log files](#).

Performance after initial ingestion

In some Tableau Server environments where specific content that is updated very frequently (for example, through high-frequency schedules or command line or API requests), the indexing process might get over saturated. In these cases, as the server admin, you might consider enabling event throttling to better preserve Catalog performance. For more information, see `metadata.ingestor.pipeline.throttleEventsEnable`.

Note: When event throttling is enabled, users might notice an intended delay in content changes in Catalog.

Out of memory errors

In some cases, Tableau Server out of memory errors can occur as a result of problems with ingesting complex content. If you suspect ingestion is the cause of the out of memory errors on your Tableau Server, contact and work with Tableau Support to metadata.ingestor.blocklist from being ingested to help resolve the issue.

Disable Catalog

As a Tableau Server admin, you can disable Catalog in one of two ways.

Turn off Catalog capabilities for each site

(Requires Data Management)

You can turn off Catalog capabilities at any time. When Catalog capabilities are turned off, the features of Catalog, such as adding data quality warnings or the ability to explicitly manage permissions to database and table assets, are not accessible through Tableau Server. However, Catalog continues to index published content and the metadata is accessible from the Tableau Metadata API and metadata methods in the Tableau REST API.

1. Sign in to Tableau Server using your admin credentials.
2. From the left navigation pane, click **Settings**.
3. On the General tab, under Tableau Catalog, clear the **Turn on Tableau Catalog** check box.

Stop indexing metadata on Tableau Server

To stop indexing the published content on Tableau Server, you can disable the Tableau Metadata API. To disable the Metadata API, run the `tsm maintenance metadata-services disable` command. For more information, see [tsm maintenance](#).

Get Initial Ingestion Status

After enabling the Tableau Metadata API using the `tsm maintenance metadata-services` command, you can use the Backfill API to monitor progress of initial ingestion and get

status information for content and lineage backfills.

The steps described below must be performed by a server admin and recommended to be used in conjunction with Step 7: Monitor initial ingestion progress and validate its status in the Enable Tableau Catalog topic.

Step 1: Authenticate using the REST API

To access the Backfill API, you must first authenticate against Tableau Server and get a token. You can do this using the Tableau REST API. For more information, see [Signing In and Signing Out \(Authentication\)](#) in the REST API Help.

Alternatively, you can sign in to Tableau Server using your admin credentials.

Step 2: Make a GET request

Make the following GET request or paste the URL into your browser:

```
http://my_tableau_server/api/metadata/v1/control/backfill/status
```

The request initially returns information about content backfill. When content backfill is complete, lineage backfill information is returned.

- For content backfill, the request returns a status summary and additional status information for each content type depending on what content is available on Tableau Server. Indexing for each content type happens concurrently.
- For lineage backfill, the request returns a status summary.

Status values from the response

The following values are returned by the Backfill API.

- **contentBackfillTotalDurationSeconds** and **lineageBackfillTotalDurationSeconds** is how much time has progressed, in seconds, on the respective backfill type. When **backfillComplete** is true, **contentBackfillTotalDurationSeconds** and **lineageBackfillTotalDurationSeconds** is the total time spent to complete the respective backfill type.

For content backfill:

- **contentType** can show the following content types: PublishedDatasource, Database, DatabaseTable, Metric, Workbook, and Flow.
- **contentId** is the identifier of the last indexed item.
- **successfullyIngestedCount** is the number of items successfully indexed.
- **failedIngestedCount** is the number of items that could not be indexed.
- **durationSeconds** is the time spent, in seconds, to index items for the content type.
- **totalCount** is the total number of items to index.
- **checkpointCreatedTime** is the last recorded time, in UTC, an item was indexed. The Backfill API checks for the last indexed item every five minutes.
- **backfillComplete** is `true` when indexing is complete for all items of the content type.

For lineage backfill:

- **totalCount** is the total number of lineage relationships to index.
- **processedCount** is the number of indexed lineage relationships.
- **lastLineageConnection** is the last indexed lineage relationship.
- **backfillComplete** is `true` when indexing is complete for all lineage relationships.

Example response

The request returns JSON text. To view the JSON in a more readable format, you can use a JSON viewer or browser add-on.

```

Get Eventing Status

After you have enabled Tableau Catalog (or the Tableau Metadata API) in your Tableau Server environment, you can use the Eventing API to gauge indexing performance.

The steps described below must be performed by a server admin.

Step 1: Authenticate using the REST API

To access the Eventing API, you must first authenticate against Tableau Server and get a token. You can do this using the Tableau REST API. For more information, see [Signing In and Signing Out \(Authentication\)](#) in the REST API Help.

Alternatively, you can sign in to Tableau Server using your admin credentials.

Step 2: Make a GET request

Make the following GET request or paste the URL into your browser:

```
http://my_tableau_server/api/metadata/v1/control/eventing/status
```

Status values from the response

The following values are returned by the Eventing API.

- **contentType** is the content type that was most recently indexed.
- **queueSize** is the number of items in the indexing queue. The larger the queue size, the longer it can take for items to show in Catalog or Metadata API. If the queue size increases over time, you might need to adjust backgrounder capacity to support the non-interactive containers and indexing process. For more information, see [Memory for non-interactive microservice containers](#).
- **checkpointCreatedTime** is the last recorded time, in UTC, an item was indexed. The Eventing API checks for the last indexed item every five minutes.

Example response

The request returns JSON text. To view the JSON in a more readable format, you can use a JSON viewer or browser add-on.

```
{  
  
  "contentType": "PublishedDatasource",  
  
  "queueSize": 312,  
  
  "checkpointCreatedTime": "2020-07-29T23:50:25.763Z"  
}
```

Use Lineage for Impact Analysis

Knowing where your data comes from is key to trusting the data, and knowing who else uses it means you can analyze the impact of changes to data in your environment. The lineage feature in Tableau Catalog helps you do both these things.

When you have a Data Management license and Tableau Catalog enabled, you have access to lineage information for your content. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

Navigate lineage

To see the lineage for an asset, first navigate to the asset's page. Your options for this step include:

- Search for the asset and select it.
- Navigate to it from **Explore**.
- If it's an external asset (such as a database or table) that's not in a project, navigate to it through **External Assets**. (This option also works for external assets that *are* in projects.)

Then select the **Lineage** tab.

Note: Lineage data for flows won't show if the flow includes parameter values. For more information about using parameters in flows see [Create and Use Parameters in Flows](#) in the Tableau Prep help.

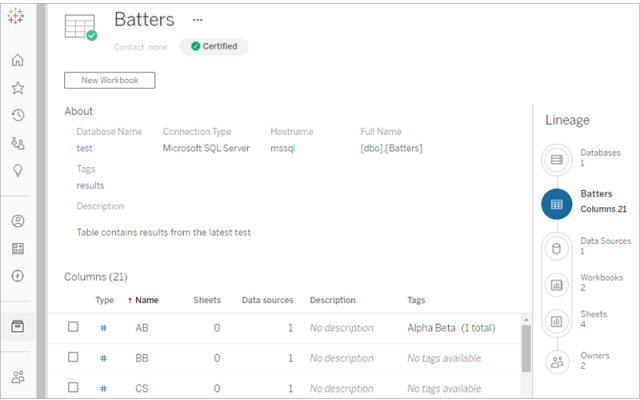

The screenshot shows the Tableau interface for the 'Orders (superstore)' data source. The 'Lineage' tab is selected, and the 'Lineage' panel on the right displays a hierarchy: Databases (1) -> Tables (1) -> Orders (superstore) Fields (7). The main table lists fields with their types, names, sheet counts, and descriptions.

Type	Name	Sheets	Description	Sensitivity
Text	Ship Mode	0	No description	
Date	Ship Date	3	No description	
Number	Orders (Count)	0	No description	
Text	Order ID	3	No description	
Date	Order Date	3	No description	
Text	Customer ID	0	No description	
Number	Address ID	3	No description	

Lineage shows dependencies in relationship to the lineage anchor, which is the asset selected. A lineage anchor can be a database, table, workbook, published data source, virtual connection, virtual connection table, lens, metric, or flow. (In the image above, the anchor is the

Tableau Server on Windows Help

"Orders (superstore)" data source, and in the image below, the anchor is the "Batters" table.) All the assets below the anchor depend, either directly or indirectly, on the anchor and are called outputs or downstream assets. The assets above the anchor are the assets the anchor is either directly or indirectly dependent on and are called inputs or upstream assets.

Starting in Tableau Cloud June 2023 and Tableau Server 2023.3, lineage pages for data sources include search and filtering (in the top-right of the fields list) that allow you to quickly find fields of interest or relevance.

When you select a field in a data source or a column in a table, the lineage is filtered to show only downstream assets that depend on the field (or column) or upstream inputs to the field (or column) as in this 'Superstore' workbook example that shows the lineage filtered for the Commission (Variable) field:

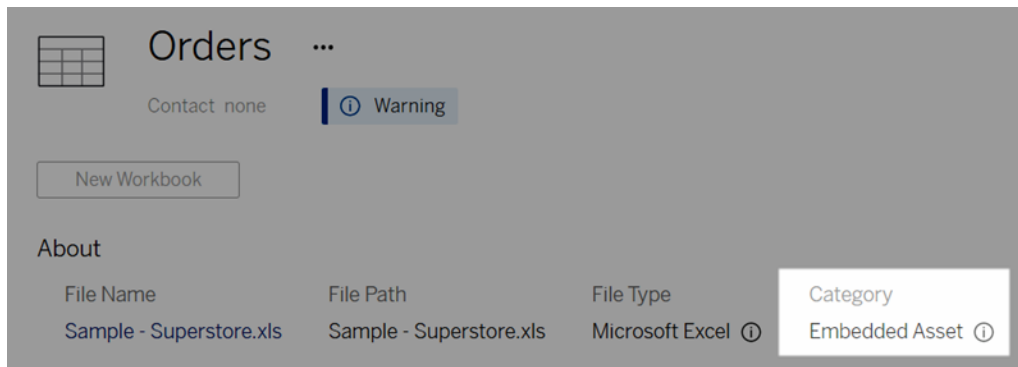

You can select an upstream or downstream asset in the Lineage pane to see its details. For example, when you select Metrics, the list of metrics depending on this workbook appears to the left of the Lineage pane.

From the Lineage pane, you can navigate to any asset related to your initial choice, in this case the workbook, by following the links that interest you.

Embedded asset appears in External Assets

Tableau Catalog treats an external asset as 'embedded' if the **Include external files** check box is selected when a data source or workbook is published. When an external asset (database, table, or file) is embedded in published Tableau content (workbooks, data sources, and flows), the external asset is used by the content, but is not shareable with other users. That embedded external asset appears in the lineage upstream from its Tableau content and is listed in External Assets.

To see if an external asset is embedded, go to the external asset's detail page and see if "Embedded Asset" is listed under **Category**.

For information about embedded data, see [Publishing data separately or embedded in workbooks](#) in Tableau Desktop and Web Authoring Help.

Lineage and custom SQL connections

When you view the lineage of a connection that uses custom SQL, keep in mind the following:

- Lineage might not be complete.
- Catalog doesn't support showing column information for tables that it only knows about through custom SQL.
- Field details cards might not contain links to connected columns, or might not show any connected columns at all.
- Column details cards might not contain links to fields that use the column, or might not show any fields at all.

For more information, see [Tableau Catalog support for custom SQL](#) in the Tableau Desktop and Web Authoring Help.

Catalog doesn't support cubes

Cube data sources (also known as multidimensional or OLAP data sources) are not supported by Tableau Catalog. Tableau content (such as a data source, view, or workbook) that relies on cube data does not display any cube metadata or cube lineage in Catalog.

Mismatch between lineage count and tab count

You might notice a mismatch in the count of assets between the Tableau Catalog Lineage tool and the tabs in Tableau Server or Tableau Cloud.

The count mismatch is explained by the fact that each—lineage count vs. tab count—counts assets a different way. For example, at any given point in time, Catalog can count only assets that are indexed, whereas Tableau Server or Tableau Cloud counts any assets that are published. Other reasons for count differences include whether:

- You have "View" permissions for the asset.
- An asset is hidden.
- Any fields are used in a workbook.
- An asset is directly or indirectly connected to.
- An asset is in a Personal Space.

Workbook count mismatch example

As an example, here's how the tab count vs. the lineage count is determined for workbooks.

Connected Workbooks tab counts workbooks that meet both these criteria:

- Connects to the data source (whether or not any fields are actually used in the workbook).
- The user has permissions to view (whether it's a worksheet, dashboard, or story).

Tableau Catalog Lineage counts workbooks that meet all these criteria:

- Has been indexed by Tableau Catalog.
- Connects to the data source and uses at least one field in the data source.

- Contains worksheets, including dashboards or stories that contain a worksheet, that use at least one field in the data source.

When metadata is blocked because of limited permissions, or the asset is in a Personal Space, Catalog still counts the workbook. But instead of seeing some of the sensitive metadata, you see **Permissions required**. For more information, see Access lineage information.

Use email to contact owners

At the end of the lineage is Owners. The list of owners includes anyone assigned as the owner or contact for any content downstream from the lineage anchor.

You can email owners to let them know about changes to the data. (To email owners, you must have the 'Overwrite' (Save) capability on the lineage anchor content.)

1. Select **Owners** to see the list of people who are impacted by the data in this lineage.
2. Select the owners you want to send a message to.
3. Click **Send Email** to open the email message box.
4. Enter the Subject and your message in the text box, and click **Send**.

Data Labels

Data labels are metadata that you can attach to data assets. Data labels help classify data and pass information to users. For example:

- One published data source might be considered more authoritative than other, similarly named ones. The certification data label can help you inform users which data source is recommended.
- A column in a database might contain outdated information. A warning data label can help you tell workbook authors and viewers that the data may not be up to date.
- A table of employee income might contain sensitive information that shouldn't be shared. A sensitivity data label can inform users that they should take care when using data from the table.
- A number of published data sources might be groupable based on the department that published them. A custom label name with a custom category can help express the departments responsible for the different data sources.

Note: Data labels are a more recent and extensible way of thinking about ways to classify metadata. Certifications and data quality warnings, which were part of the Data Management license long before the term "data labels" existed, are now considered categories in the broader data label concept, along with the Sensitivity Labels released in Tableau Cloud June 2023 and Tableau Server 2023.3.

A Data Management license is required for all data label operations except for those related to the certification of published data sources.

Assets you can label

Users can add labels to the following Tableau content and external assets:

- Databases
- Tables
- Columns (except for certification) (*column labels introduced in Tableau Cloud October 2022 / Server 2022.3*)
- Data sources
- Flows
- Virtual connections
- Virtual connection tables

Label names and categories

Each label has a name and category. The names and categories built-into Tableau are:

Name	Category
Certified	Certification
Deprecated	Data Quality Warning
Stale data	Data Quality Warning
Under maintenance	Data Quality Warning

Warning	Data Quality Warning
Extract refresh failed	Data Quality Warning
Flow run failed	Data Quality Warning
Sensitive data ¹	Sensitivity

¹*In Tableau Cloud March 2023 / Server 2023.1 and earlier, the Sensitive data label uses the Data Quality Warning category.*

Beginning with Tableau Cloud October 2023 and Tableau Server 2023.3, using the label manager on the Data Labels page or the REST API, an administrator can customize the built-in labels or create entirely new label names and categories. (Using the REST API, Tableau Cloud Administrators have been able to modify some built-in labels and add others in certain categories since June 2023.) For information, see [Manage Data Labels](#).

Label categories

A label's category affects where and how the label appears, whether it appears on assets that are downstream from the one it's attached to, and which parts are customizable, among other things.

Certification

In a self-service environment with multiple publishers and a lot of assets, it can be difficult to find recommended content. Using certification, you can mark assets as trusted, and the assets display badges in various places across Tableau. For complete information, see [Use Certification to Help Users Find Trusted Data](#).

Data quality warnings

Identifying problematic data is important for building trust with users. Data quality warnings allow you to mark data assets that have known issues. When you attach a data quality warning to an asset, a warning shows on it and any downstream assets that use it, making data con-

sumers aware of problems with the source data. For example, if you mark a database table as deprecated, users viewing workbooks based on that table may see a warning.

Furthermore, data quality warnings can be set automatically when an extract refresh or flow run fails, and removed again when it succeeds. And using the Data Labels page or the REST API, administrators can create new, customized data quality warning labels, adding nuance and specificity to the warnings that users can choose from. For complete information, see [Set a Data Quality Warning](#)

Sensitivity labels

Some data needs to be handled differently. Using Sensitivity labels, you can relay data sensitivity information to consumers of that data. When you mark an asset as sensitive, users browsing Tableau Cloud will see badges on it and any downstream assets that use it. For example, if you mark a database column as sensitive, a user browsing Tableau Cloud may see a "sensitive data" badge. Furthermore, using the **Data Labels** page or the REST API, administrators can create new, customized sensitivity labels, adding nuance and specificity to the range of classifications that users can choose from when using sensitivity labels.

Note: Sensitivity labels were introduced in Tableau Cloud June 2023 and Tableau Server 2023.3. Earlier versions of Tableau Cloud and Tableau Server relay data sensitivity through the "Sensitive data" data quality warning instead of using a dedicated sensitivity category.

For complete information, see [Sensitivity Labels](#).

Custom label categories

Sometimes you need to classify data in a way that isn't covered by certification, data quality warnings, or sensitivity labels. Using custom categories that administrators define, you can use labels to categorize assets in any way that your organization sees fit. For example, an administrator in your organization might create a category called "Department" with labels in it

for sales, marketing, and other departments, ready to be applied to assets on your site. For complete information, see [Labels with Custom Categories](#).

Note: The ability for administrators to create label names and categories through the label manager was released with Tableau Cloud October 2023 and Tableau Server 2023.3. Tableau Cloud administrators could use the REST API in a more limited way to create custom label names with built-in categories in June 2023.

Permissions required to interact with data labels on assets

Permissions required to view, add, update, and delete labels on assets are listed below:

- To view a data label, you must have **read** permissions on the associated asset.
- To add, update, or delete a data label other than a certification label, you must have **write** permission on the associated asset.
- To add, update, or delete a certification label, you must be an administrator, or else you must be a project leader or product owner for the project the asset is in.
- To add, update, or delete a certification label for an external asset *not* in a project, you must have the **change permissions** permission on the associated asset.

Comparison of data labels and tags

Tableau Cloud and Tableau Server also feature another solution for asset classification: Tags. Data labels and tags differ in significant ways:

Area	Data Labels	Tags
Structure and control	Administrators control the range of data labels	No administrative control over the range of tags users add
Permissions	Ability to add/update/remove data labels controlled through asset permissions	Explorers and Creators can tag any assets that they can view
Appearance	Data label iconography is easily seen and	Tags are generally less vis-

	color-coded by category and visibility level	ible than data labels and have no iconography
Inheritance	Some data labels (like warnings and sensitivity labels) show on downstream assets	No inheritance
Searchability	Can be used as search filter criteria	Can be used as search filter criteria
API accessible	Access via REST API and Metadata API possible	Access via REST API and Metadata API possible
License requirements	Requires a Data Management license (except for the certification of published data sources)	No licensing requirements
Use	Structured categorization focused on providing important information that can influence users' use of data	Open ended method to categorize assets

For more information on tags, see [Use Tags](#) in the Tableau Desktop and Web Authoring Help.

Use Certification to Help Users Find Trusted Data

In a self-service environment with multiple publishers, it's common for a project on Tableau Server to contain a variety of content that is named similarly, or is based on the same or similar underlying data, or is published without any descriptive information about it. When this is the case, analysts might lack confidence about the data they should use.

To help your users find the data that's trusted and recommended for their type of analysis, you can *certify* the data that complies with your organization's data standards.

Certification complements the Recommendations Training Schedule feature by offering a way to promote data through curation.

In addition to certifying published data sources, if you have a Data Management license for Tableau Server or Tableau Cloud:

Tableau Server on Windows Help

- If Tableau Catalog is enabled, you can certify databases and tables that are associated with your Tableau content. (For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help.)
- Starting in Tableau 2022.1, you can certify virtual connections and virtual connection tables.

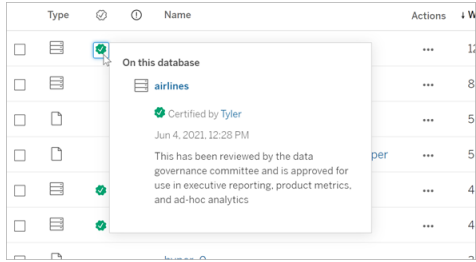

How certification helps users find trusted data

When you certify an asset, users see a green badge or green check mark, depending on where the asset is being viewed.

Certified data sources rank higher in search results and are added to recommended data sources.

In addition, you can provide notes about the certification status, which appear when users click the badge, or in a tooltip when they hover over the data source icon in web authoring or Tableau Desktop. The information also shows who certified the data source.

For more information, see the How to certify data steps below.

Create guidelines for selecting data to certify

As with most Tableau functionality, certification is flexible. You can define for your organization the criteria you use to determine when to certify a data source (or database or table). As you do this, you might want to document and share your guidelines. As new data sources are published, the guidelines can help you and other administrators or project leaders to be consistent with your certification choices. They can also help users understand what certification means.

Whether you use the same certification criteria across all projects, or define unique criteria for each project, the important thing is to be clear about what certification means in your environment.

Who can certify data

To certify a data source, you must

- be a Server or Site Administrator, *or*
- have a site role of Explorer (Can Publish) or Creator *and* be the project owner or have the Project Leader capability for the project containing the data you want to certify.

To certify virtual connections and virtual connection tables, you must have a Data Management license in your environment, and you must

- be a Server or Site Administrator, *or*
- have a site role of Explorer (Can Publish) or Creator *and* be the project owner or have the Project Leader capability for the project containing the data you want to certify.

To certify databases or tables, you must have Tableau Catalog enabled in your environment, and you must

- be a Server or Site Administrator, *or*
- have the Set permissions capability on the database to certify that database or any tables within that database.

How to certify data

The data you can certify depends on whether you have a Data Management license, and if you do, if you have Tableau Catalog enabled in your environment.

- All users with the right permissions can certify data sources.
- If you have a Data Management license, users with the right permissions can also certify virtual connections and virtual connection tables.
- If Tableau Catalog is enabled, users with the right permissions can also certify databases, tables, and files.

Take the following steps to certify the data.

1. Sign in to Tableau Server.
2. Navigate to the asset. This step depends on the type of asset you want to certify:
 - Data source or virtual connection - on the **Explore** page, select **All Data Sources** or **All Virtual Connections**.
 - Virtual connection table - on the **Explore** page, select **All Virtual Connections**, and select the virtual connection that contains the virtual connection table you want to certify. Then select the virtual connection table.
 - Database or table - on the **Explore** page, navigate to the database or table. Or on the **External Assets** page, select **Databases and Files** or **Tables**.
3. On the page, select the More actions menu (...) next to the asset name you want to certify.
4. Select **Data Labels > Certification** (Tableau Cloud and Tableau Server 2023.3 and later) or **Edit Certification** (Tableau Server 2023.1 and earlier) and then do the following:
 - Use the toggle to certify the asset. (In earlier versions of Tableau Server, use the checkbox.)
 - Add a note that gives users context for the certification status, intended use for the data, or other helpful information. Information you add to the **Note** section appears in the certification badge or tooltip, mentioned earlier in How certification

helps users find trusted data. You can format the text in a message with bold, underline, and italics, and include a link or an image. To see text formatting tips, click the information (i) icon above the **Save** button.

The screenshot shows the 'Certification' dialog box for a data source named 'Batters'. At the top, there is a header 'Certification' and an information icon. Below the name, there is a toggle switch for 'This data source is certified' which is currently turned on. Underneath, it states 'This asset is trusted and recommended.' A text area labeled 'Message (required)' contains the text 'The Baseball Department has approved this data source.' with a character count of '54 / 4,000'. Above the text area are 'Edit' and 'Preview' buttons. At the bottom, there are three buttons: 'Clear Settings', 'Cancel', and 'Save'. An information icon with the text 'Formatting Guide' is located near the bottom right of the text area.

5. Select **Save**.

Customize certification

Beginning with Tableau Cloud June 2023 and Tableau Server 2023.3, using the label manager on the Data Labels page or the REST API, an administrator can change the certification description that users see in the certification dialog. For information, see [Manage Data Labels](#).

Set a Data Quality Warning

Data quality warnings are a feature of Tableau Catalog, part of the Data Management offering for Tableau Server and Tableau Cloud. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

When Tableau Catalog is enabled in your environment, you can set data quality warnings on data assets so that users of that data are aware of issues. For example, you might want to let users know that a data source has been deprecated, or that a refresh has failed for an extract data source, or that a table contains sensitive data.

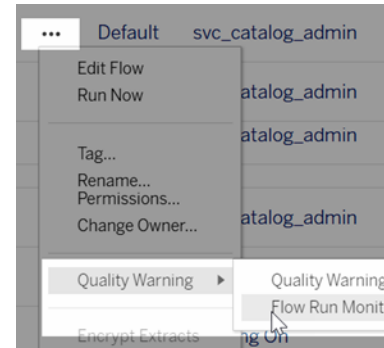

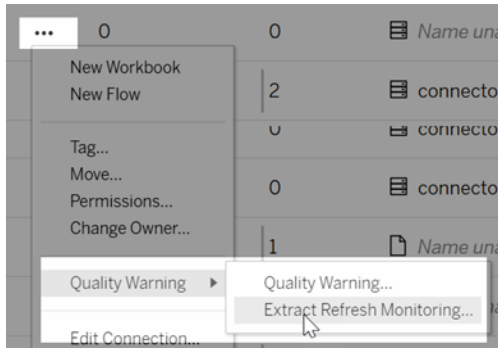

You can set data quality warnings on data sources, databases, tables, flows, virtual connections, virtual connection tables, and columns.

Data quality warnings for data sources, databases, tables, and flows were introduced in version 2019.3 for Tableau Cloud and Tableau Server. Data quality warnings for virtual connections and virtual connection tables were added in Tableau Cloud March 2022 and Tableau Server 2022.1, and for columns in Tableau Cloud October 2022 and Tableau Server 2022.3.

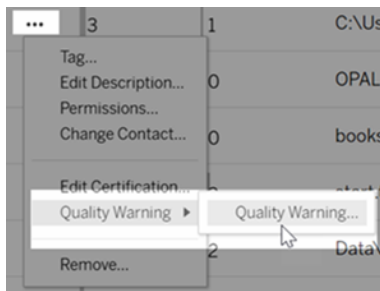

About data quality warnings

There are two kinds of data quality warnings you can set. The first kind is visible to users until you remove it. The second kind is generated by Tableau when you set Tableau to monitor for refresh failures of extract data sources or flow run failures. Starting in Tableau Cloud October 2023 and Tableau Server 2023.3, in addition to setting monitoring warnings at the asset level, you can also turn extract refresh and flow run monitoring on or off for the entire site at once. For information about site-wide monitoring, see [Site-wide monitoring for extract refresh and flow run failures](#).

For extracts and flows, you can set one data quality warning of each kind per asset.

For databases, tables, columns, virtual connections, virtual connection tables, and live data sources, you can set only one quality warning.

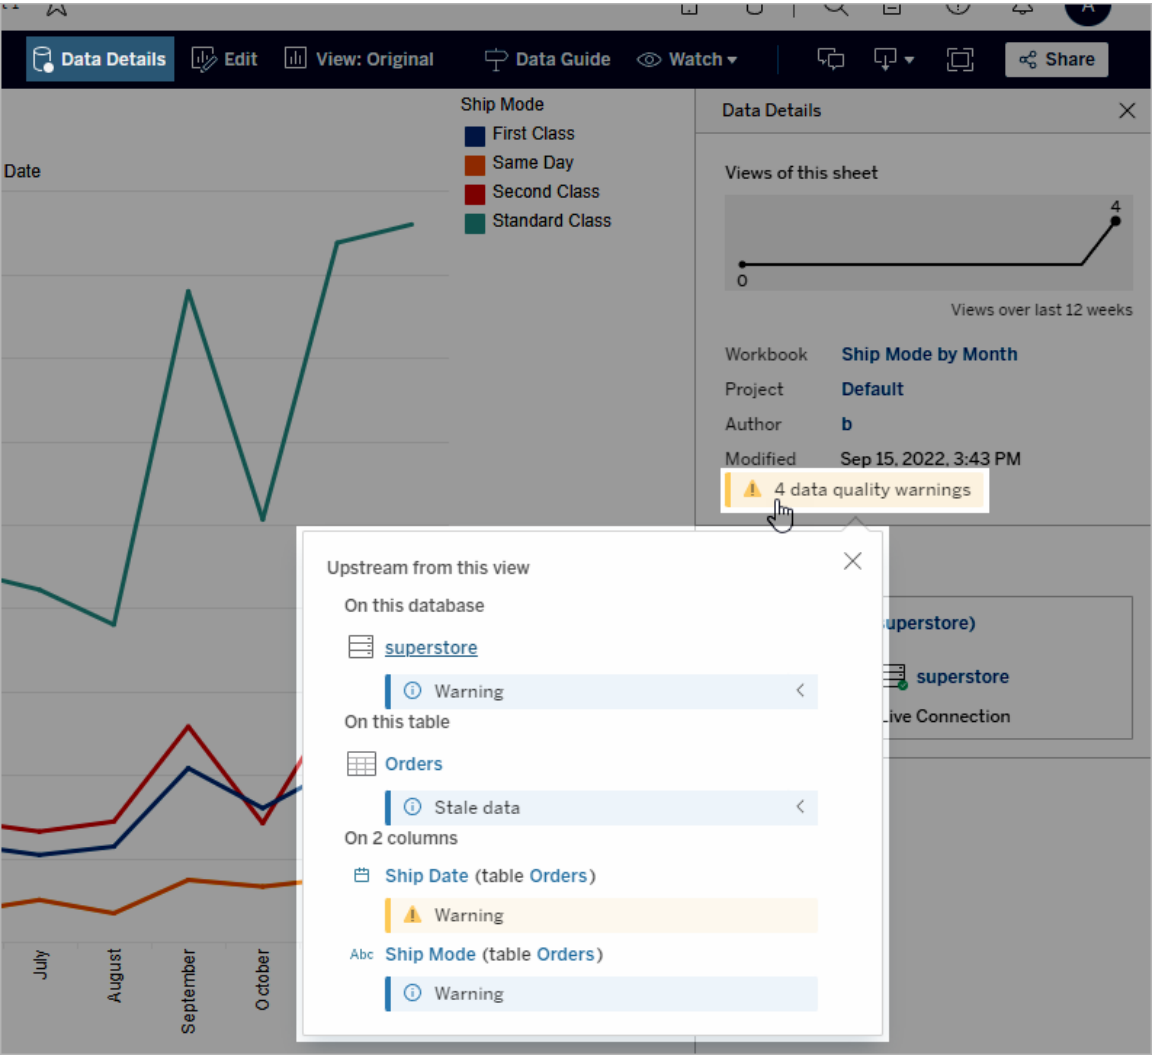

When you set the first kind, it's visible to users until you remove it using the data quality dialog box. You can also use the dialog box to make any updates to the quality warning you set.

When you set Tableau to monitor for extract data source refresh failures or flow run failures, if a warning is generated, it's visible to users until the extract refresh or flow run is successful. You can update or remove a warning by opening and editing the contents in the dialog box.

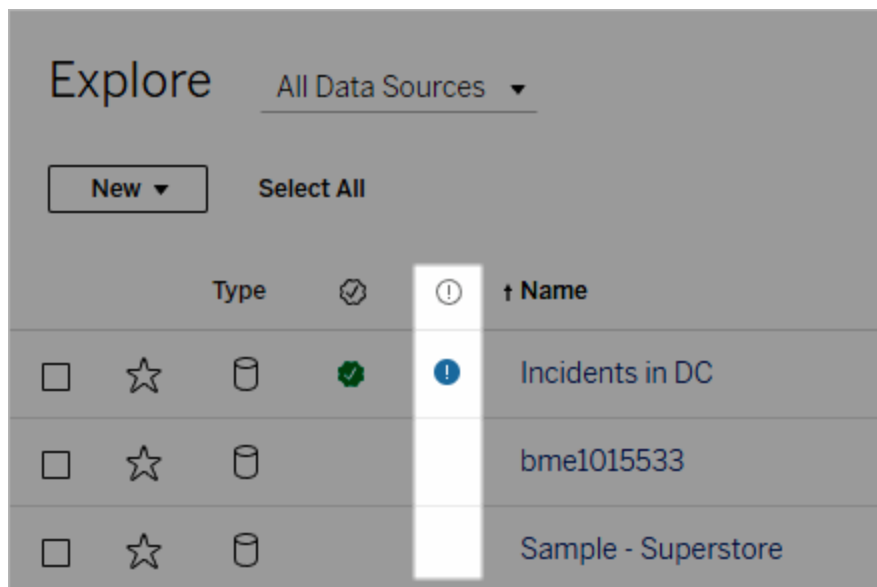

Note: You can set both kinds of data quality warnings and enable high visibility using REST API. For more information, see [Add Data Quality Warning](#) in the Tableau REST API Help.

Who can see the data quality warning

In Tableau Server and Tableau Cloud, when you set a warning on a data source, flow, database, table, column, virtual connection, or virtual connection table, the warning is visible to users of the asset and any assets downstream from it. For example, a warning set on a table is visible to users looking at a dashboard with an upstream dependency on that table - users see a warning icon on the dashboard's Data Details tab and can open the pane to see the details. Warnings are visible elsewhere in Tableau as described in Set high visibility for a data quality warning.

When exploring some types of content using list view, Tableau Server and Tableau Cloud users also see data quality warnings in a column.

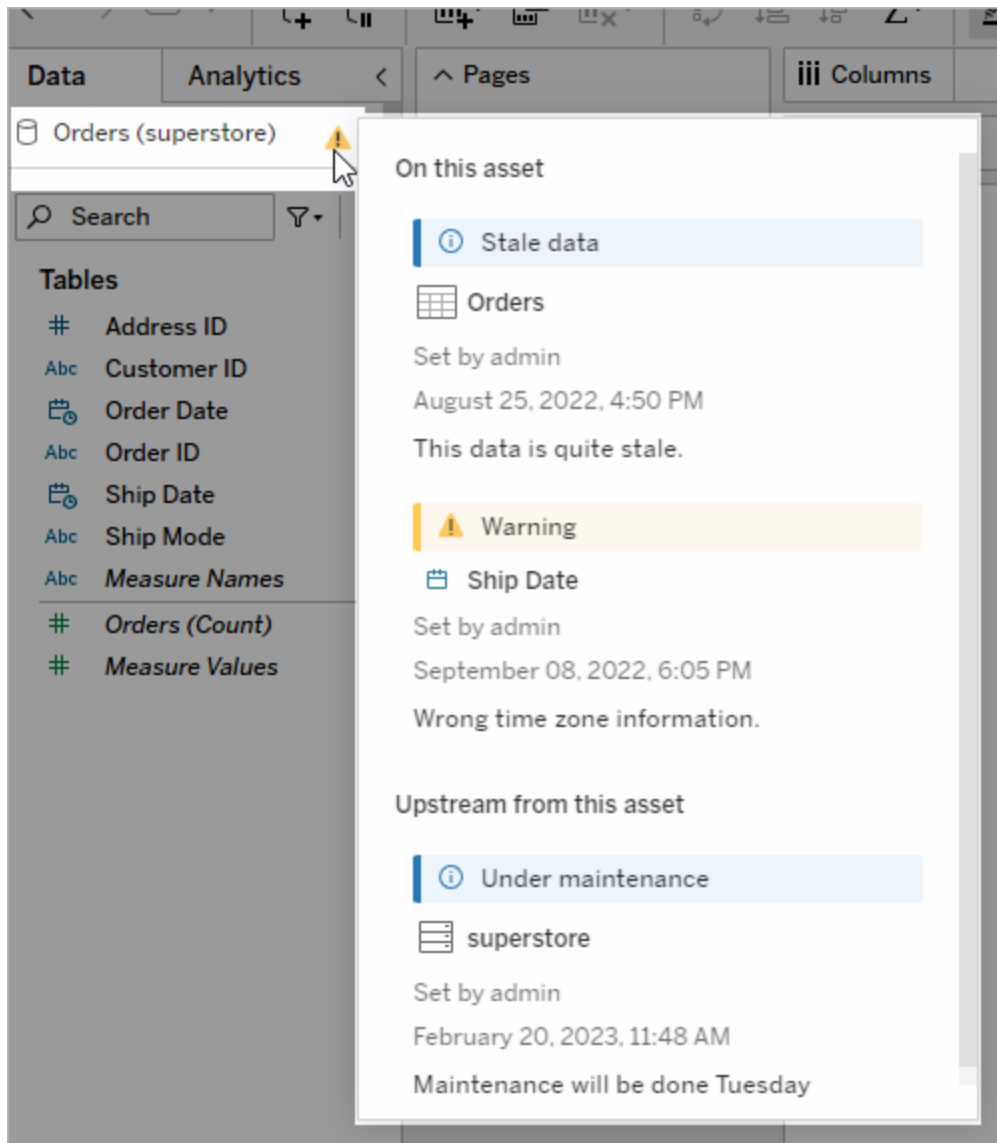

In Tableau Desktop and Tableau Web Authoring, users see a warning icon (either a blue circle or a yellow triangle with an exclamation point) on the Data tab in a workbook sheet when either

- a warning is set on a data source used in the workbook, or
- there is a warning upstream from the data source used in the workbook

Note: Data quality warnings for columns and virtual connections do not appear in Tableau Desktop.

To see the details of the warning, hover over the warning icon with the cursor.

Data quality warnings in subscriptions

Administrators can turn on data quality warnings in email subscriptions so that when users subscribe to a view, the email they get includes high visibility data quality warnings associated with that view. Emails with high visibility data quality warnings contain:

- Links to relevant views or workbooks with their **Data Details** pane open.
- Links to relevant upstream assets, such as data sources, tables, or databases.

Administrators can turn on data quality warnings in email subscriptions by selecting the **Data Quality Warnings in Subscriptions** option on the Tableau Server or Tableau Cloud site settings page. For more information, see [Data Quality Warnings in Subscriptions in the Site Settings Reference](#).

How to set a quality warning

You can set one of several different data quality warnings on an asset. Starting in Tableau Cloud June 2023 and Tableau Server 2023.3, an administrator can add to the list of available data quality warnings by [customizing data labels](#). The following data quality warnings are built-in:

- Warning
- Deprecated
- Stale data
- Under maintenance

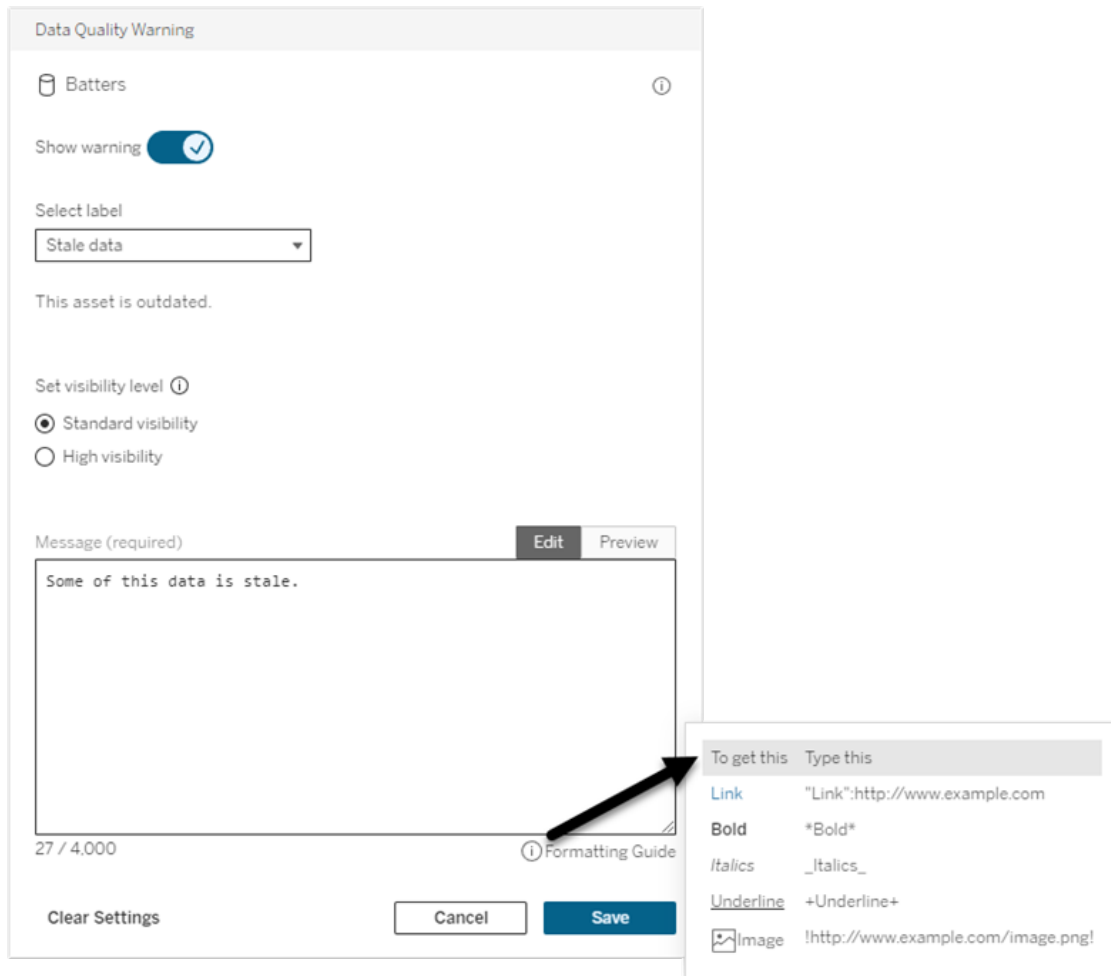

Beginning in Tableau Cloud June 2023 and Tableau Server 2023.3, "Sensitive data" is no longer a data quality warning, but is a sensitivity label instead. See [Sensitivity Labels](#) for information. In Tableau Server 2023.1 and earlier, "Sensitive data" remains a data quality warning.

In addition to showing the data quality warning, you can include an optional message with more details about the warning.

To set a data quality warning:

1. Navigate to the asset you want to create a quality warning for. This step depends on the type of asset:
 - Data source or virtual connection - on the **Explore** page, select **All Data Sources** or **All Virtual Connections**.
 - Virtual connection table - on the **Explore** page, select **All Virtual Connections**, and select the virtual connection that contains the virtual connection table you want to certify. Then select the virtual connection table.

- Database or table - on the **Explore** page, navigate to the database or table. Or on the **External Assets** page, select **Databases and Files** or **Tables**.
 - Column - on the **Explore** or External Assets page, navigate to the table that contains the column.
2. Select the actions menu (. . .) next to the asset, and then select **Quality Warning**. (For columns in Tableau Server 2022.3 and earlier, instead select the column, and then click the actions dropdown and select **Quality Warning**.)
 3. Turn the warning on.
 4. Select the warning label from the dropdown list.
 5. Set the visibility level.
 6. Enter a message that users will see in the warning details. You can format the text in a message with bold, underline, and italics, and include a link or an image. To see text formatting tips, click the information (i) icon above the **Save** button.
 7. Select **Save**.

How to set a monitoring quality warning

You can set Tableau to monitor for two events: extract data source refresh failure and flow run failure. When the event occurs, Tableau generates a quality warning that appears in the same places that a manual quality warning appears.

You can turn on monitoring explicitly on the extract or flow, or, starting in Tableau Cloud October 2023 and Tableau Server 2023.3, you can enable site-wide monitoring for all extract refresh and flow run failures. For information on site-wide monitoring, see [Site-wide monitoring for extract refresh and flow run failures](#).

To explicitly monitor for either an extract refresh or flow run failure:

1. Select the actions menu (. . .) next to the extract data source or flow you want to create a warning for, and then select the appropriate option:
 - In Tableau Cloud and Tableau Server 2023.3 and later:
 - **Data Labels > Extract Refresh Monitoring**
 - **Data labels > Flow Run Monitoring**
 - In Tableau Server 2023.1 and earlier:
 - **Quality Warning > Extract Refresh Monitoring**
 - **Quality Warning > Flow Run Monitoring**
2. Enable the warning.
3. Set the visibility level. (Older versions of the dialogs have a checkbox for high visibility.)
4. (Optional) Enter a message that users will see in the warning details if the extract refresh or flow run fails. You can format the text in a message with bold, underline, and italics, and include a link or an image. To see text formatting tips, click the information (i) icon above the **Save** button.
5. Click **Save**.

Site-wide monitoring for extract refresh and flow run failures

Starting in Tableau Cloud October 2023 and Tableau Server 2023.3, an administrator can turn on site-wide monitoring to add or remove data quality warnings for extract refresh failures

and flow run failures. You can control this feature through the Settings page, under the Extract Refresh and Flow Run Monitoring section:

Extract Refresh and Flow Run Monitoring

- ☒ Turn on extract refresh monitoring for all extracts on this site (recommended)
- ☒ Turn on flow run monitoring for all flows on this site (recommended)

These settings are turned on by default for all new sites. Sites that existed before the change will have the settings turned off, but an administrator can turn them on.

Interaction of site-wide monitoring and explicit monitoring

The interaction of explicit monitoring on assets and site-wide monitoring of all assets is as follows:

- If monitoring is explicitly turned on for an asset *and* site-wide monitoring is turned on, the explicit settings on the asset take precedence over the site setting. This includes properties like visibility level and message.
- When you turn off site-wide monitoring:
 - Assets *with* monitoring explicitly turned on won't be changed.
 - Assets *without* monitoring explicitly turned on will stop monitoring for extract refresh or flow run failures, and warnings that arose from extract refresh or flow run failures on those assets will be removed.
 - Catalog ingestion performance might be temporarily reduced as Catalog re-ingests assets that may no longer have warning labels.

Site-wide monitoring was released in Tableau Cloud October 2023 and Tableau Server 2023.3. There is no interaction of explicit monitoring and site-wide monitoring in earlier versions.

Set high visibility for a data quality warning

There are times when you want to make sure that users of a visualization know important information about the data they're viewing, whether it be that the data is stale, or that the source has been deprecated, or that the flow run has failed. You can do this by setting the

visibility level to high in the Data Quality Warning dialog box, as described in [How to set a data quality warning](#).

When enabled, a notification appears when anyone opens a published view affected by this warning.

High visibility warnings are identified with a yellow warning symbol, which makes them more visible elsewhere in Tableau, as in these examples:

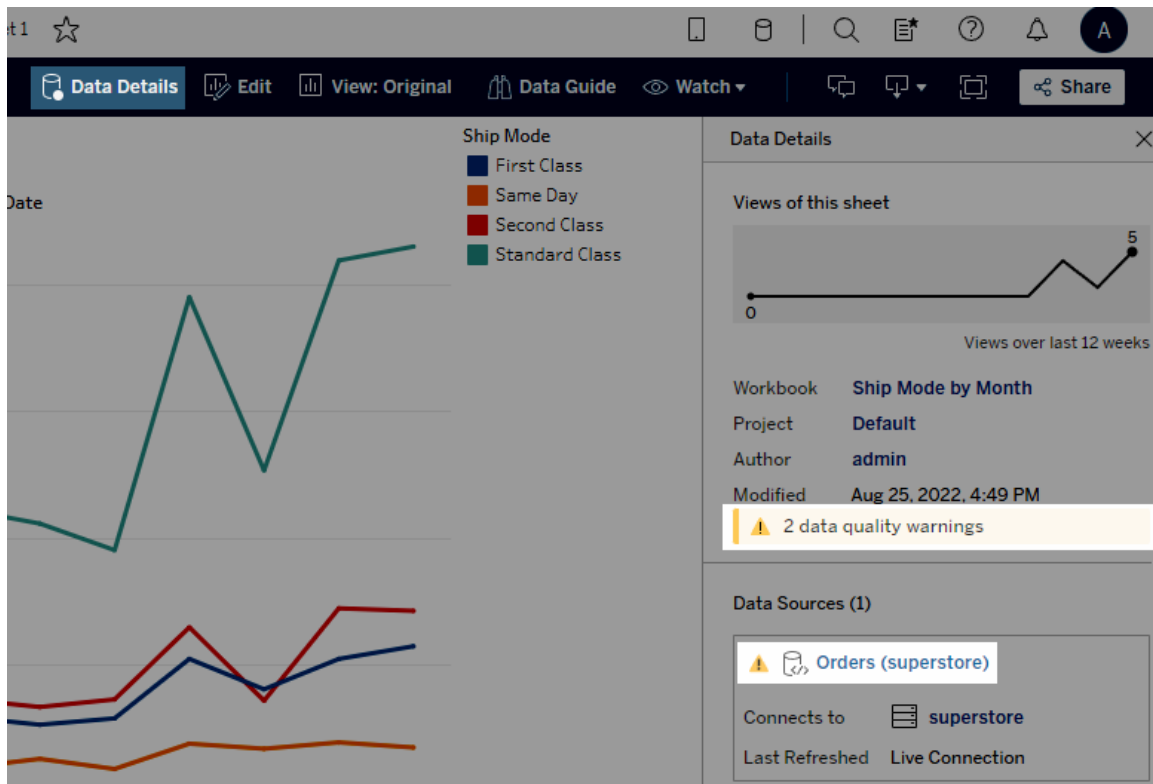

On the External Assets page:

On a database page:

On the Data Details pane:

You can change a high visibility warning to normal visibility by changing the visibility level in the **Data Quality Warning** dialog box.

Remove a data quality warning

When a warning no longer applies, you can remove it by navigating to the data asset with the warning.

1. Navigate to the asset you want to create a quality warning for. This step depends on the type of asset:
 - Data source or virtual connection - on the **Explore** page, select **All Data Sources** or **All Virtual Connections**.
 - Virtual connection table - on the **Explore** page, select **All Virtual Connections**, and select the virtual connection that contains the virtual connection table you want to certify. Then select the virtual connection table.
 - Database or table - on the **Explore** page, navigate to the database or table. Or on the **External Assets** page, select **Databases and Files** or **Tables**.

- Column - on the **Explore** or External Assets page, navigate to the table that contains the column.
2. Select the actions menu (. . .) next to the asset, and then select **Quality Warning**. (For columns in Tableau Server 2022.3 and earlier, instead select the column, and then click the actions dropdown and select **Quality Warning**.)
 3. Turn the warning off.
 4. Select **Save**.

Who can do this

To set a data quality warning, you must either

- be a server or site administrator, or
- have the **Overwrite** capability for the asset.

Customize Data Quality Warnings

Beginning with Tableau Cloud June 2023 and Tableau Server 2023.3, using the label manager on the Data Labels page or the REST API, an administrator can change the data quality warnings that users see in the data quality warning dialog, or create entirely new ones. For information, see Manage Data Labels.

Sensitivity Labels

Some data needs to be handled more carefully. To ensure trust and security, it's important that users know which data that is. Starting in Tableau Cloud June 2023 and Tableau Server 2023.3, if you have a Data Management license, Tableau offers a new category of data label: *Sensitivity labels*. Users can use sensitivity labels to indicate the level of care that should be taken when creating views or sharing information. Furthermore, sensitivity labels can co-exist on the same asset as other labels, such as certification and data quality warnings. And, using the label manager on the **Data Labels** page or the REST API, an administrator can create new sensitivity labels to suit the needs of their organization.

Note: In Tableau Cloud March 2023 and Tableau Server 2023.1 and earlier, data sensitivity was expressed using the "sensitive data" data quality warning. Because only one

data quality warning could be attached to an asset, a "sensitive data" warning couldn't co-exist with other data quality warnings. With the upgrade to Tableau Cloud June 2023 and Tableau Server 2023.3, "sensitive data" data quality warnings were migrated to sensitivity labels.

Sensitivity labels can be attached to the same types of assets that other **data labels** can.

Attach a sensitivity label to an asset

To attach a sensitivity label to an asset:

1. Select the actions menu (. . .) next to the asset, and then select **Data Labels > Sensitivity Label**.
2. Turn the label on using the **Show label** toggle.
3. Select the sensitivity label value from the dropdown list.
4. Enter a message to display to users if desired. You can format the text in a message with bold, underline, and italics, and include a link or an image. To see text formatting tips, hover over the information (i) icon above the **Save** button.
5. Select **Save**.

Remove a sensitivity label from an asset

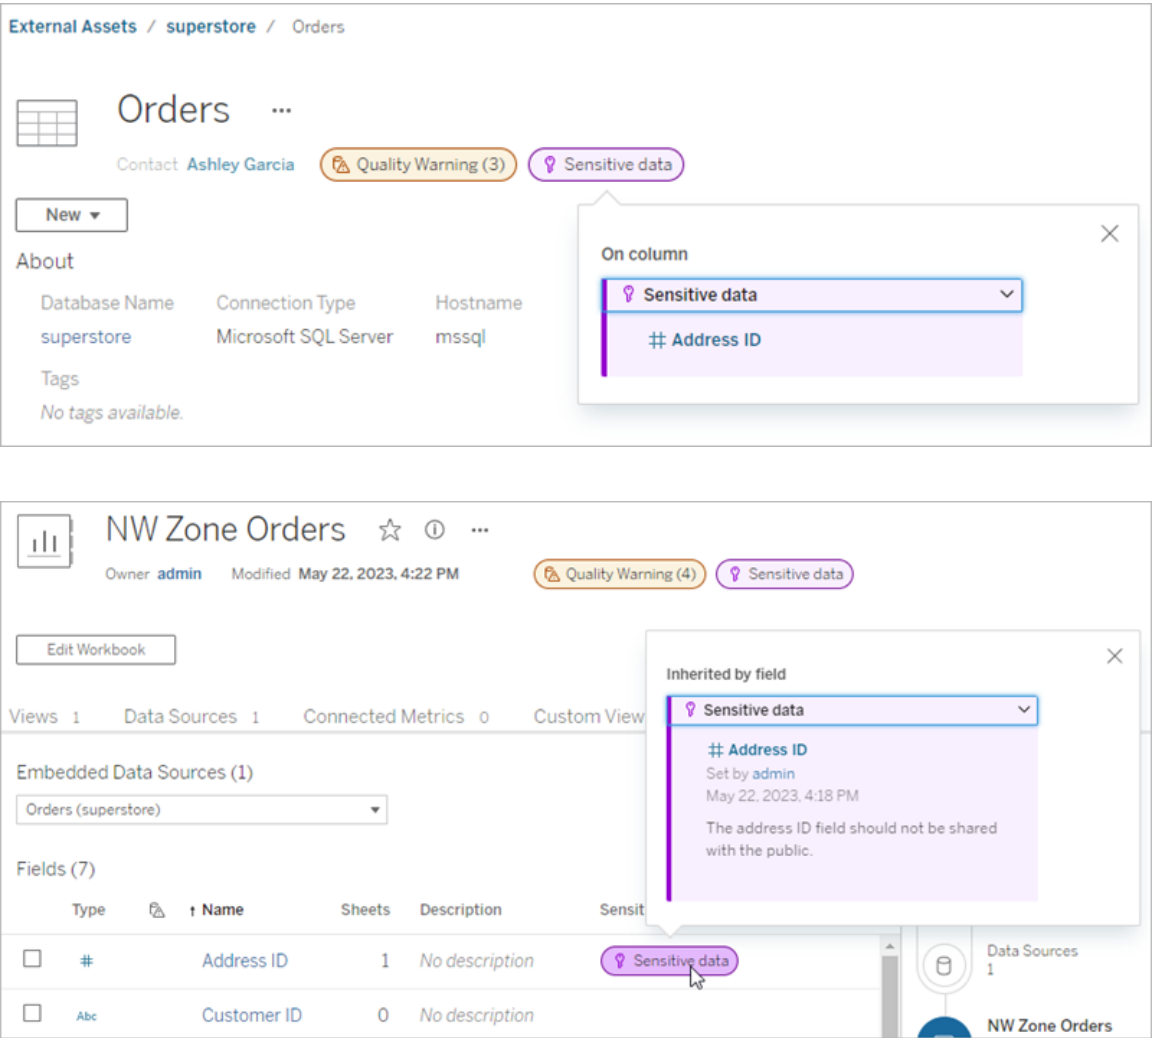

To remove a sensitivity label from an asset:

1. Select the actions menu (. . .) next to the asset, and then select **Data Labels > Sensitivity Label**.
2. Depending on your need, either turn off the label or clear the settings:
 - If you think you might want to save the label and its message for later, turn the label off with the **Show label** toggle.

- To return the label value and message to their defaults, click **Clear Settings**.
3. Select **Save**.

Where sensitivity labels appear

Sensitivity labels appear on assets when navigating Tableau Server. Like data quality warnings, sensitivity labels appear downstream from the assets on which they're attached. For example, a sensitivity label on a column appears in the columns row of the table page, again at the top of the table page, and on the database page.

Visibility

By default, the built-in sensitivity label named "Sensitive data" is high visibility and appears purple. If an administrator has changed the built-in sensitivity label to standard visibility or created other standard visibility sensitivity labels, those will appear gray.

Sensitivity labels in email subscriptions

Administrators can turn on sensitivity labels in email subscriptions so that when users subscribe to a view, the email they get includes high visibility sensitivity labels associated with that view. Emails with high visibility sensitivity labels contain:

- Links to relevant views or workbooks with their **Data Details** pane open.
- Links to relevant upstream assets, such as data sources, tables, or databases.

Administrators can turn on sensitivity labels in email subscriptions by selecting the **Data Quality Warnings in Subscriptions** option on the Tableau Server or Tableau Cloud site settings page. For more information, see Data Quality Warnings in Subscriptions in the Site Settings Reference.

Who can do this

To set a sensitivity label, you must either

- be a server or site administrator, or
- have the **Overwrite** capability for the asset.

Customize sensitivity labels

There is only one built-in sensitivity label: *Sensitive data*. Starting in Tableau Cloud June 2023 and Tableau Server 2023, using the labels manager on the **Data Labels** page or the REST API, an administrator can create new sensitivity label values or change the name and description of an existing one. Typical additions (name and description) might be:

- **Public:** Available to the public to view.
- **Internal:** Restricted to company employees and contractors. This data must not be shared publicly, but it can be shared with customers, partners, and others under a non-disclosure agreement (NDA).

- **Confidential:** Available to an approved group of employees and contractors. This data isn't restricted by law, regulation, or a company master service agreement (MSA). It can be shared with customers, partners, and others under an NDA.
- **Restricted:** Available only to an approved group of employees and contractors. This data is likely restricted by law, regulation, an NDA, or a company MSA.
- **MissionCritical:** Available only to a small group of approved employees and contractors. Third parties who are given access could be subject to heightened contractual requirements. This data is almost always restricted by law, regulation, an NDA, or a company MSA.

For information, see [Manage Data Labels](#).

Labels with Custom Categories

Tableau offers several data labels – certification, quality warnings, and sensitivity labels – that cover a wide variety of ways to classify data. Still, there may be times that users need other labels and categories that match other use cases. Starting in Tableau Cloud October 2023 and Tableau Server 2023.3, users can classify assets using labels with custom categories that an administrator has defined. For example, an administrator could create a category called "Department" with labels for the sales, service, and operations departments ready to be applied to assets.

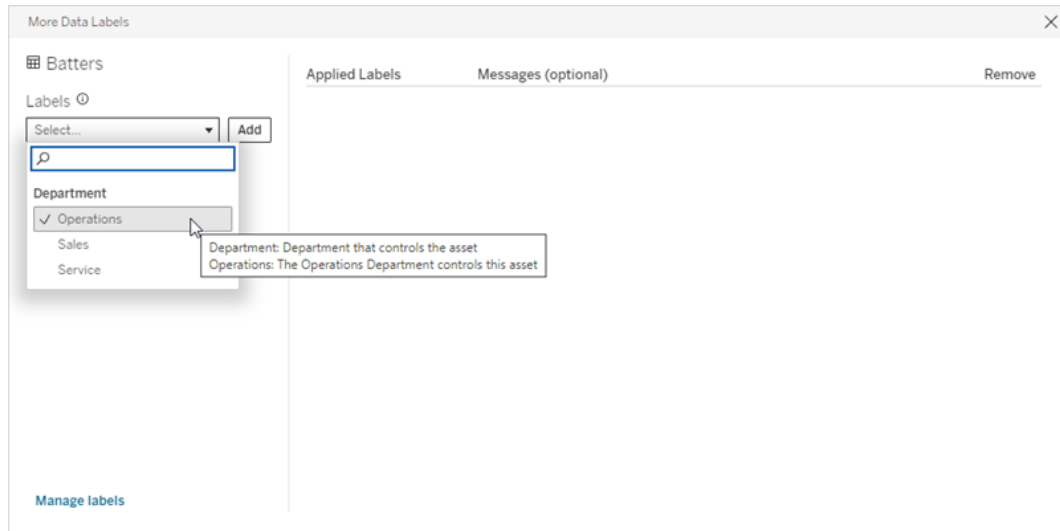

Labels with custom categories require a Data Management license with Tableau Catalog enabled, and can be attached to the same kinds of assets that other data labels can. However, labels with custom categories don't show on downstream assets the way that data quality warnings and sensitivity labels do.

Note: If you're an administrator who wants to create custom categories and labels, see [Manage Data Labels](#).

Attach labels with custom categories to an asset

To attach a label with a custom category to an asset:

1. Open the **More Data Labels** dialog for the asset you want to attach the label to. To do this, select the actions menu (. . .) next to the asset, and select **Data Labels > More Data Labels...**
2. Select the **Labels** dropdown. The label names are arranged by label category, and you can scroll through them.

3. Select the label to attach, then select **Add** next to the **Labels** dropdown. The label appears in the **Applied Labels** list on the right side of the dialog.
4. To add an optional label message on this specific asset, select the pencil in the **Messages (Optional)** column, then select **Save**.

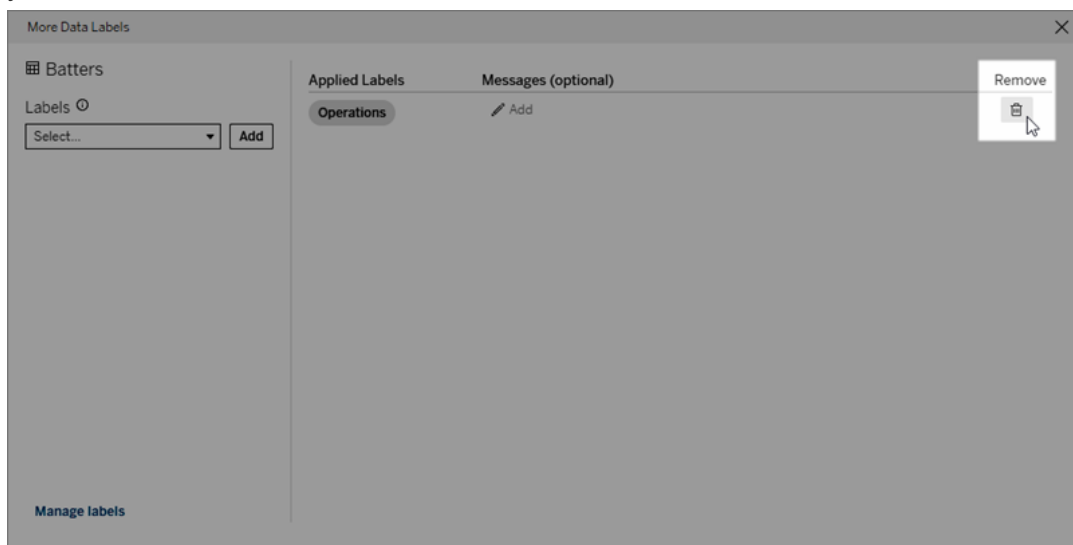

5. Repeat steps 2 through 5 for each label you want to add.

6. When you're finished adding labels, close the dialog. (Select the X in the dialog box's upper right corner or select something outside of the dialog box to close it.)

Remove labels with custom categories from an asset

To remove a label with a custom category from an asset:

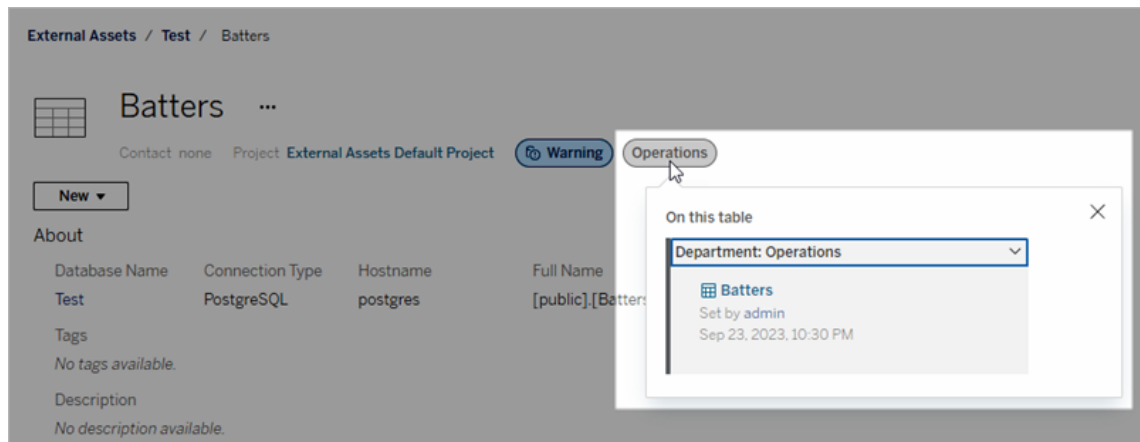

1. Open the **More Data Labels** dialog for the asset you want to attach the label to. To do this, select the actions menu (. . .) next to the asset, and select **Data Labels > More Data Labels....**
2. In the **Applied Labels** section of the dialog, select the trash icon in the row for the label you'd like to remove.

3. Repeat step 2 for each label you want to remove.
4. When you're finished removing labels, close the dialog. (Select the X in the dialog box's upper right corner or select something outside of the dialog box to close it.)

Where labels with custom categories appear

Custom labels appear on assets when navigating Tableau Cloud and Tableau Server.

Unlike quality warnings and sensitivity labels, labels with custom categories do not appear downstream from assets they're attached to. For example, suppose your organization has a custom label category named "Department" to which a custom label named "Sales" belongs. If you attach the "Sales" label to a table called "Orders", the label only appears on the "Orders" table and not on workbooks downstream from it.

Who can do this

To add a label with a custom category to an asset (or to remove one from an asset), you must either

- be a server or site administrator, or
- have the Overwrite capability for the asset.

Customize a label with a custom category

For information on how administrators can create or edit custom categories and labels that appear in the **More Data Labels** dialog, see Manage Data Labels.

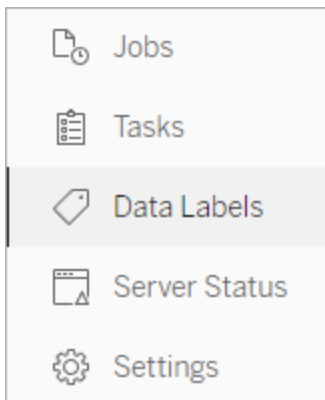

Manage Data Labels

Starting in Tableau Cloud October 2023 and Tableau Server 2023.3, if you have a Data Management license and are an administrator, you can use the label manager to create or edit label names and label categories. These customizations affect the way that labels appear throughout Tableau when users interact with labels.

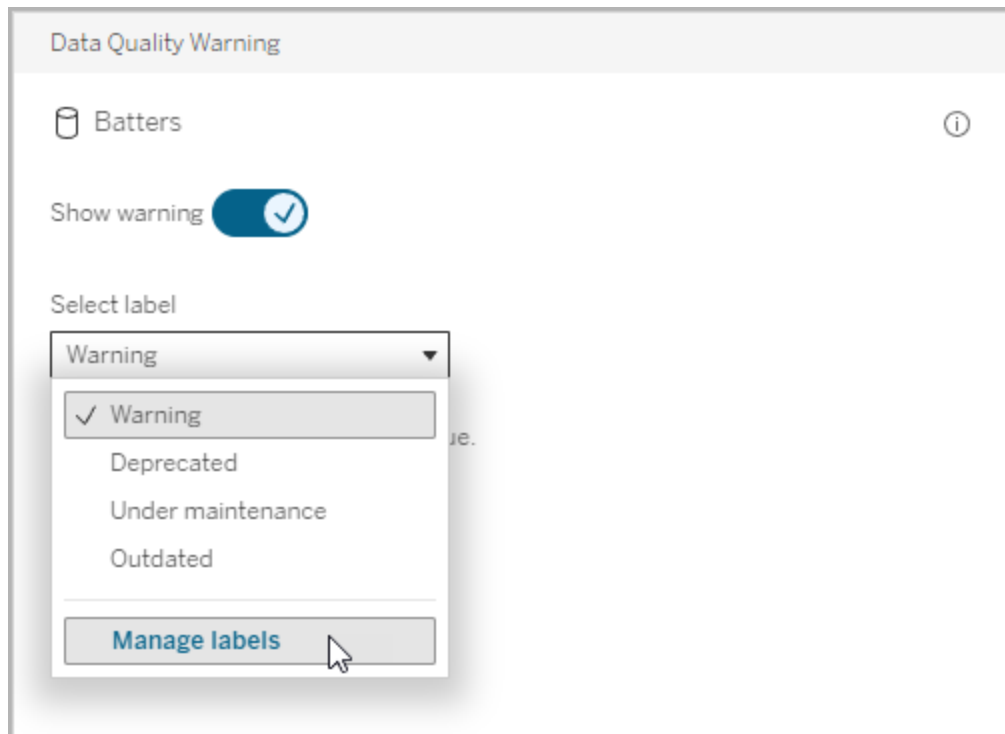

Note: You can also use the REST API's `labelValues` methods and `labelCategories` methods to create and edit labels and label categories. (Tableau Cloud administrators have been able to create and modify label names and descriptions using the `labelValues` methods since Tableau Cloud June 2023.) For information, see the Metadata Methods in the [REST API Reference](#).

Label Manager

To use the label manager, log in as an administrator and select **Data Labels** from the left navigation pane.

Alternatively, if you are logged in as an administrator and you open one of the dialogs for adding labels to an asset (for example, the data quality warning dialog), a **Manage labels** link shows in the selection dropdown or elsewhere in the dialog. The **Manage labels** link leads to the Data Labels page.

The label manager page shows a row for each label, sorted by label category. Each row includes the label category, name (here known as the value), an **Actions** menu (...) to perform actions on that label, visibility, and description.

Data Labels					
Use labels to classify data.					
<input type="button" value="New Label"/> <input type="button" value="Select All"/>					
Category	Value	Actions	Visibility	Description	
<input type="checkbox"/> Certification	 Certified	...	-	This asset is trusted and recommended.	
<input type="checkbox"/> Warning - Extract refresh failed	 Extract refresh failed	...	Standard ⓘ	This asset's most recent extract refresh failed.	
<input type="checkbox"/> Warning - Flow run failed	 Flow run failed	...	Standard ⓘ	This flow's most recent run failed.	
<input type="checkbox"/> Data Quality Warning	 Deprecated	...	High ⓘ	This asset is no longer maintained and shouldn't be used.	
<input type="checkbox"/> Data Quality Warning	 Stale data	...	High ⓘ	This asset is outdated.	
<input type="checkbox"/> Data Quality Warning	 Under maintenance	...	Standard ⓘ	This asset is undergoing maintenance.	
<input type="checkbox"/> Data Quality Warning	 Warning	...	Standard ⓘ	This asset has a general quality issue.	
<input type="checkbox"/> Sensitivity	 Sensitive data	...	High	This asset contains sensitive information.	
<input type="checkbox"/> Department	 Operations	...	-	The Operations Department controls this asset	
<input type="checkbox"/> Department	 Sales	...	-	The Sales Department controls this asset	
<input type="checkbox"/> Department	 Service	...	-	The Service Department controls this asset	

Use the label manager to:

- **Edit built-in labels**
 - Example: You change the name of the built-in "Under maintenance" quality warning to "Maintenance mode".
 - Example: You change the visibility of extract refresh monitoring labels from standard visibility to high visibility so that they show in views.
- **Create new labels that use the existing built-in categories**
 - Example: You add a new sensitivity label called "Confidential".
- **Revert a built-in label to its default name, description, and visibility**
 - Example: You previously changed the "Stale data" quality warning name to "Outdated", and you want to revert it to its default name.
- **Create custom categories**
 - Example: You create a new label category called "Department" with the intention of adding labels for different business units.
- **Create new labels in custom categories**
 - Example: You create new "Sales", "Service", and "Operations" labels for your newly created "Department" category.

Properties of Data Labels

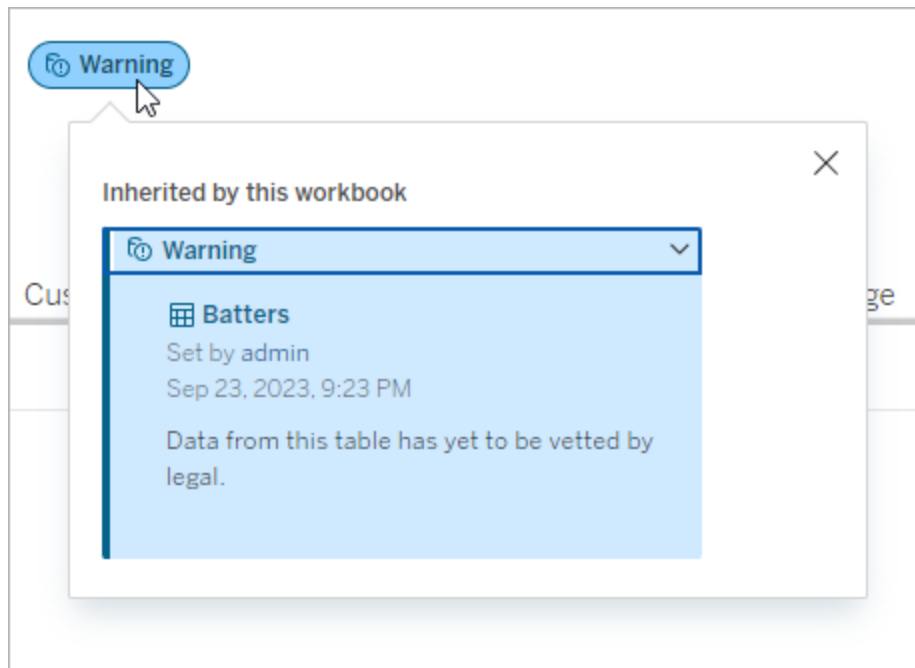

A label has a name, a category, and a description. Labels with a Quality Warning or Sensitivity category also have a visibility level.

Name

The label name is the common name for the label as it appears in various places. For example, here the label name "Warning" is selected in the Data Quality Warning dialog.

Here the label name "Warning" shows in the header of the "Batters" table page, and again in the label details.

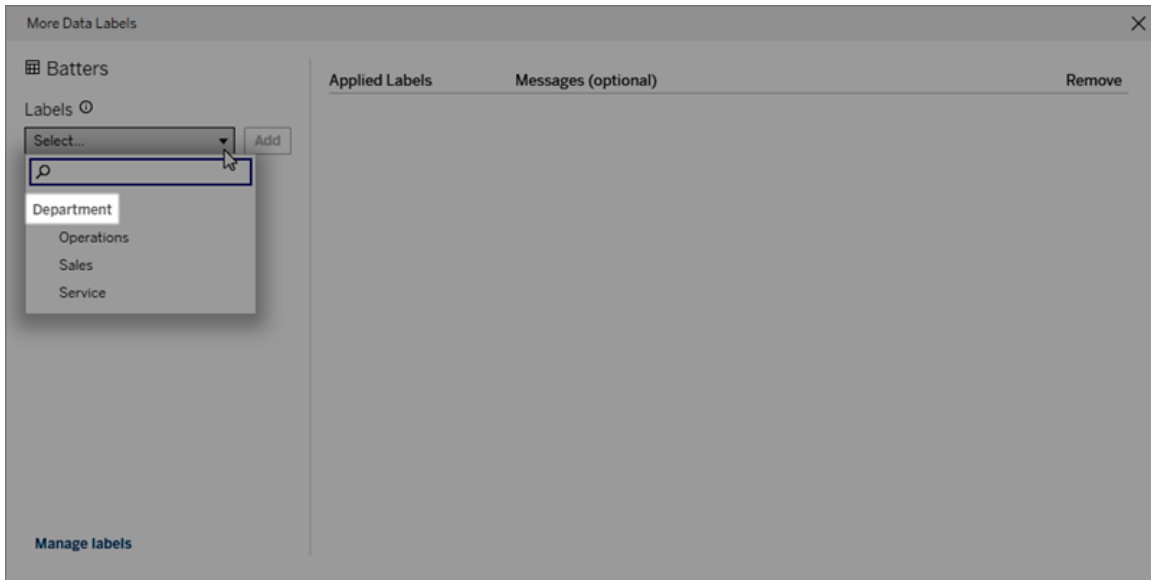

Category

The label category affects where and how the label appears, whether it appears on assets that are downstream from the one it's attached to, and which parts are customizable, among other things. For example, quality warnings and sensitivity labels appear on downstream assets, but other labels with other categories don't. Another example: You can change the description of a certification label, but not the name.

The built-in categories are **certification**, **quality warning**, and **sensitivity**.

For custom categories, users see the category in the **Labels** dropdown of the **More Data Labels** dialog. For example, here the category name "Department" appears above the labels it includes.

Description

The label description appears in various places, including under the dropdown menu for label selection, and helps the user understand what the label is used for. For example, the label description in this Data Quality Warning dialog says "This asset has a general quality issue."

Visibility

The visibility of a label determines its appearance. High visibility labels appear in more places and may appear more urgent to the user. You can only set the visibility level on Quality

Warning or Sensitivity labels. Furthermore, if a label has a category of Quality Warning, users with permissions can override the default visibility on each asset that they attach a Quality Warning label to. For more information, see the [Set a Data Quality Warning and Sensitivity Labels](#) topics.

Create a data label

To create a label:

1. From the **Data Labels** page, select **New Label**.
2. Select a category from the **Label** category dropdown.
3. Enter the label name in the **Label value** field.
4. Enter the label description in the **Label description** field. You can format the text with bold, underline, and italics, and include a link or an image. To see text formatting tips, hover over the information (i) icon above the **Save** button.
5. If the label has a category of Quality Warning or Sensitivity, set the visibility level. For more information, see [Visibility](#).
6. Select **Save**.

Limitations for creating labels

- You can't create a label in the certification category. The certification category allows only the single, built-in label.

- You can't create new monitoring warnings. However, the extract refresh failure and flow run failure warnings can be edited in limited ways, as described in the "Edit a label" section.
- The maximum length for a label name is 24 characters.
- The maximum length for a label description is 500 characters.

Edit a data label

To edit an existing label:

1. From the **Data Labels** page, select the **Actions (...)** menu in the label's row. Or select the row using its checkbox on the left and click the **Actions** dropdown at the top of the label list.
2. Select **Edit**.
3. (Optional) Change the label name using the **Label value** field.
4. (Optional) Change the label description using the **Label description** field.
5. (Optional) If the label has a category of Quality Warning or Sensitivity, set the visibility level. For more information, see [Visibility](#).
6. Select **Save**.

Limitations for editing labels

- You can't change the category on an existing label.
- The maximum length for a label name is 24 characters.
- The maximum length for a label description is 500 characters.

The different label categories allow different degrees of label editing. The following table lists the editable properties of labels with the given categories:

Label category	Can edit label category	Can edit label names	Can edit label descriptions	Can edit label visibility
Certification	No	No	Yes	N/A
Quality Warning	No	Yes ¹	Yes	Yes ²
Sensitivity	No	Yes	Yes	Yes

Custom	No	Yes	Yes	N/A
--------	----	-----	-----	-----

- ¹ You can't edit the label name (label value) of the extract refresh or flow run monitoring warnings.
- ² The visibility level you set for quality warnings is the default visibility. Users with permission can override the default visibility when they attach a quality warning to an asset. For more information, see [Visibility](#).

Delete a data label

To delete an existing label:

1. From the **Data Labels** page, select the **Actions** (...) menu in the label's row. Or select the row using its checkbox on the left and click the **Actions** dropdown at the top of the label list.
2. Select **Delete**.

Limitations for deleting labels

- You can't delete a built-in label. Built-in labels are the default labels in Tableau Server.

Revert a built-in data label to its defaults

If an administrator previously edited a built-in label, the **Actions** menu for that label contains **Revert to default label**. Reverting a label to its defaults returns the label's name (value), description, and visibility to its built-in defaults.

Create a data label category

To create a label category:

1. From the **Data Labels** page, select **New Label**.
2. In the **New Label** dialog, select **New Category**.

3. Enter the category name in the **Category name** field.
4. Enter the category description in the **Category description** field. You can format the text with bold, underline, and italics, and include a link or an image. To see text formatting tips, hover over the information (i) icon above the **Save** button.
5. Select **Save**.

Limitations for creating label categories

- The maximum length for a category name is 24 characters.
- The maximum length for a category description is 500 characters.

Edit a data label category

To edit a label category:

1. From the **Data Labels** page, select the label category, then select the pencil icon. Or from the **New Label** or **Edit Label** dialogs, select the category in the **Label category** dropdown and then select the pencil icon next to **Category description**.

2. (Optional) Change the category name using the **Category name** field.
3. (Optional) Change the category description using the **Category description** field.
4. Select **Save**.

Limitations for editing label categories

- You can't edit a built-in category.
- The maximum length for a category name is 24 characters.
- The maximum length for a category description is 500 characters.

Delete a data label category

Currently, there isn't a method to delete a label category through the regular Tableau Server interface. To delete a category using the REST API, see the [Delete Label Category method](#) in the REST API Reference.

Scenarios for customization

Scenario: Customize a built-in data label

Suppose you decide that the data quality warning called "Warning" could be more specific. As an administrator, you change the label name from the default ("Warning") to something you think is more useful to your organization: "Not approved". The label name "Not approved" now appears in label dialogs when users are selecting labels.

Alternatively, you could change the label description so that the user learns more about the warning in the label dialog. For example: "This asset doesn't meet quality standards required by the marketing department."

Scenario: Create a custom data label

Suppose you want users to have more granular control over classifying the sensitivity of assets. You create two new sensitivity labels with the names "Public" and "PII". The custom label names "Public" and "PII" now appear in the label dialog dropdowns and descriptions, alongside the built-in sensitivity label.

Scenario: Create a new data label category and associated data labels

Suppose you need a way to identify the business units that are responsible for assets. You create a new label category called "Department". Then you create three new labels – "Sales", "Service", and "Operations" – with "Department" as their category. The category "Department" and the three associated labels now appear in the **More Data Labels** dialog for users to attach to assets.

Manage Dashboard Extensions in Tableau Server

Dashboard extensions are web applications that run in custom dashboard zones and can interact with the rest of the dashboard using the [Tableau Extensions API](#). Dashboard extensions give users the ability to interact with data from other applications directly in Tableau.

Note: You must be a server administrator to enable dashboard extensions on the server, or to block specific extensions from running. You must be a server administrator to add extensions to the safe list and to control the type of data the extensions can access. The server administrator can also configure whether users on the site will see prompts when they add or view extensions in a dashboard. For information about extension security and recommended deployment options, see [Extension Security - Best Practices for Deployment](#)

For information about using dashboard extensions in Tableau, see [Use Dashboard Extensions](#).

Looking for Tableau Cloud? See [Manage Dashboard Extensions in Tableau Cloud](#).

Before you run extensions on Tableau Server

Tableau supports two types of dashboard extensions: Network-enabled extensions, which can be hosted on web servers located inside or outside of your local network and have full

access to the web, and Sandboxed extensions, which run in a protected environment without access to any other resource or service on the web.

Note: Beginning with version 2021.1.0 Tableau supports integration with Einstein Discovery through the Einstein Discovery Dashboard extension. This is a special extension that has access to data in Salesforce.com and is allowed by default. It is not considered a Network-enabled extension or a Sandboxed extension. For more information on Einstein Discovery integration, see [Tableau Server Release Notes](#).

Sandboxed extensions are hosted by Tableau and employ W3C standards, such as Content Security Policy (CSP), to ensure the extension can't make network calls outside of the hosting Tableau Server. A Sandboxed extension can query data in the dashboard, but it can't send that data anywhere outside of the sandbox. Sandboxed Extensions are supported in Tableau 2019.4 and later. By default, Sandboxed extensions are allowed to run if extensions are enabled for the site.

Network-enabled dashboard extensions are web applications and could be running on any computer set up as a web server. This includes local computers, computers in your domain, and third-party web sites. Because Network-enabled extensions could be hosted on third-party sites and could have access to the data in the dashboard, you want to only allow the extensions you trust. See [Test Network-enabled extensions for security](#).

For security, you can use the settings for dashboard extensions on Tableau Server to control and limit the dashboard extensions that are allowed to run.

- By default, Sandboxed extensions are allowed to run if extensions are enabled for the site.
- By default, no Network-enabled extensions are allowed unless they have been explicitly added to the safe list.

- By default, only extensions that use the HTTPS protocol are allowed, which guarantees an encrypted channel for sending and receiving data (the only exception is for `http://localhost`).
- If the Network-enabled extension requires full data (access to the underlying data) the extension will not be able to run on Tableau Server unless you explicitly add the extension to the safe list and grant the extension access to full data.

Control dashboard extensions and access to data

Server administrators can control a global setting to allow extensions for all sites on the server. Server administrators can also put extensions, including Sandboxed extensions, on a global block list to prevent them from running (see Block specific extensions). By default, all Sandboxed extensions are enabled on the server, but site administrators can choose to override the default and prohibit Sandboxed extensions for the site.

Change the global setting enabling extensions on the server

1. To change this setting for the server, go to **Manage All Sites > Settings > Extensions**. If the server just has a single site, the global controls appear on the settings page for the site.
2. Under Dashboard Extensions, select or clear the **Let users run extensions on this server** checkbox. If this option is not selected, extensions are not allowed to run. This global setting overrides the **Let users run extensions on this site** settings for each site.

Change the default settings for a site

Server administrators can control whether to enable extensions for the site and whether to allow Sandboxed extensions on the site. That is, if extensions are enabled on the server, the default site settings allow Sandboxed extensions to run on the site, provided the extension is not specifically blocked on the server. The default site settings allow Network-enabled extensions to run that appear on the safe list for the site. Individual Sandboxed extensions can also be added to the safe list, if Sandboxed extensions are not allowed by default.

1. To change these settings for the site, go to **Settings > Extensions**.
2. Under Dashboard Extensions, configure these options:
 - **Let users run extensions on this site**
 - **Let Sandboxed extensions run unless they are specifically blocked by a server administrator**

Server administrators can add or remove Network-enabled and Sandboxed extensions from the safe list for a site. When you add an extension to the safe list, you can control whether to allow the extension to have access to full data. See [Add extensions to the safe list and configure user prompts](#).

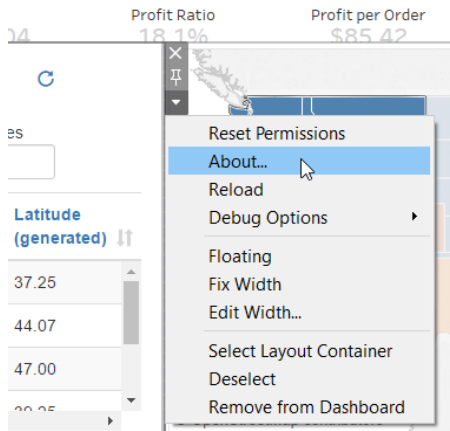

Identifying an extension

As a web application, an extension is associated with a URL. You use this URL to test and verify the extension. You also use the URL to add the extension to the safe list to allow full data access, or to the block list to prohibit any access.

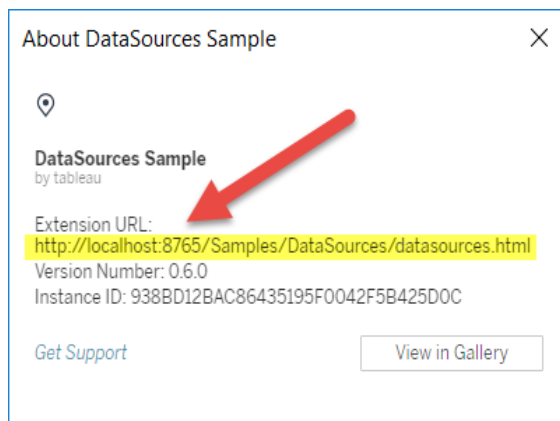

If you have the extension manifest file (.trex), an XML file that defines properties for the extension, you can find the URL from the `<source-location>` element.

```
<source-location>  
  <url>https://www.example.com/myExtension.html</url>  
</source-location>
```

If you have added the extension to the dashboard, you can find the URL from the extension properties. From the **More Options** menu, click **About**.

The About dialog box lists the name of the extension, the author of the extension, the web site of the author, along with the URL of the extension.

Add extensions to the safe list and configure user prompts

To ensure that users can use Network-enabled extensions that are trusted, you can add them to the safe list for the site. You can also add Sandboxed extensions to the safe list, if Sandboxed extensions aren't enabled by default on the site.

On the safe list, you can control whether to grant the extension full data access. By default, when you add an extension to the safe list, the extension only has access to the summary (or aggregated) data. You can also control whether users will see a prompt asking them to allow the extension access to data. You might want to add an extension to the safe list (for example,

a Sandboxed extension) so that you can configure whether or not users see the prompts. When you hide the prompt from users, the extension can run immediately.

1. Go to **Settings > Extensions**.
2. Under **Enable Specific Extensions**, add the URL of the extension. See Identifying an extension.
3. Choose to **Allow** or **Deny** the extension **Full Data Access**.

Full data access is access to the underlying data in the view, not just the summary or aggregated data. Full data access also includes information about the data sources, such as the names of the connection, fields, and tables. In most cases, if you are adding an extension to the safe list so that it can run, you will also want to allow the extension to have access to full data, if the extension requires it. Before adding extensions to the safe list, be sure to Test Network-enabled extensions for security.

4. Choose to **Show** or **Hide** the **User Prompts**.

Users see the prompts by default when they are adding an extension to a dashboard, or when they are interacting with a view that has an extension. The prompt tells users details about the extension and whether the extension has access to full data. The prompt gives users the ability to allow or deny the extension from running. You can hide this prompt from users, allowing the extension to run immediately.

Block specific extensions

The default global policy allows all Sandboxed extensions and those Network-enabled extensions that appear on the safe list for a site. Server administrators can keep specific extensions from running by adding them to the block list for the server. If an extension is on the global block list it overrides any settings for the extension on the safe list for a site.

1. To add an extension to the blocked list for the server, go to **Manage All Sites > Settings > Extensions**. On single-site installations, the block list is on the site **Extensions** settings page.

2. Under **Block Specific Extensions**, add the URL of the extension. See Identifying an extension.

Test Network-enabled extensions for security

Dashboard extensions are web applications that interact with data in Tableau using the Extensions API. Network-enabled dashboard extensions could be hosted on web servers inside or outside of your domain, and can make network calls and have access to resources on the Internet. Because of this and the potential vulnerabilities, such as cross-site scripting, you should test and vet Network-enabled dashboard extensions before users use them in dashboards on Tableau Desktop, and before you allow the extensions on Tableau Server.

Examine the source files

Dashboard extensions are web applications and include various HTML, CSS, and JavaScript files, and an XML manifest file (*.trex) that defines the properties in the extension. In many cases, the code for a dashboard extension is publicly available on GitHub and can be examined there or downloaded. In the manifest file (*.trex), you can find the source location, or URL indicated where the extension is hosted, the name of the author, and the web site of the author or company to contact for support. The `<source-location>` element specifies in the URL, the `<author>` element, specifies the name of the organization and the web site to contact for support (`website="SUPPORT_URL"`). The web site is the **Get Support** link user see in the **About** dialog box for the extension.

Many dashboard extensions reference external JavaScript libraries, such as the jQuery library or API libraries for third parties. Validate that the URL for external libraries points to a trusted location for the library. For example, if the connector references the jQuery library, make sure that the library is on a site that is considered standard and safe.

All extensions are required to use HTTPS protocol (`https://`) for hosting their extensions. You should examine the source files for the extension to ensure that any reference to external libraries is also using HTTPS or is hosted on the same web site as the extension. The one exception to the requirement of HTTPS is if the extension is hosted on the same computer as Tableau (`http://localhost`).

To the extent possible, make sure you understand what the code is doing. In particular, try to understand how the code is constructing requests to external sites, and what information is being sent in the request. In particular, check if any user-supplied data is validated to prevent cross-site scripting.

Understand data access

The Tableau Extensions API provides methods that can access the names of the active tables and fields in the data source, the summary descriptions of the data source connections, and the underlying data in a dashboard. If an extension uses any of these methods in a view, the extension developer must declare that the extension requires full data permission in the manifest file (`.trex`). The declaration looks like the following.

```
<permissions>
  <permission>full data</permission>
</permissions>
```

Tableau uses this declaration to provide a prompt to users at run time that gives them the option of allowing this access or not. If the extension uses any one of these four methods, without declaring full-data permission in the manifest file, the extension will load but the method calls will fail.

For information about how an extension accesses data from the dashboard, and the JavaScript methods used, see [Accessing Underlying Data](#) in the Tableau Extensions API. To get a better understanding about what the extension can find out about the data, you can use the [DataSources](#) sample dashboard extension (available from the [Tableau Extensions API GitHub repository](#)) to see what data is exposed when the `getDataSourcesAsync()` method is called.

Test the extension in an isolated environment

If possible, test the dashboard extension in an environment that is isolated from your production environment and from user computers. For example, add a dashboard extensions to a safe list on a test computer or virtual machine that's running a version of Tableau Server that is not used for production.

Monitor traffic created by the dashboard extension

When you test a Network-enabled dashboard extension, use a tool like [Fiddler](#), [Charles HTTP proxy](#), or [Wireshark](#) to examine the requests and responses that the extension makes. Make sure that you understand what content the extension is requesting. Examine the traffic to be sure that the extension is not reading data or code that is not directly related to the purpose of the extension.

Configure Connections with Analytics Extensions

Tableau supports a set of functions that your users can use to pass expressions to analytics extensions for integration with R, Python, and Einstein Discovery.

Note: You can use R and Python scripts to perform complex cleaning operations in your Tableau Prep flows, but configuration and functionality supported can be different. For information see [Use R and Python Scripts in your Flow](#) in the Tableau Prep help.

This topic describes how to configure sites on Tableau Server with analytics extensions.

Because Tableau Server provides an authentication mechanism, it can be more secure to expose analytics extensions functionality to users through Tableau Server than in Tableau Desktop.

For more information about user scenarios and configuring Tableau Desktop, see [Pass Expressions Analytics Extensions](#), in the *Tableau Desktop and Web Authoring Help*.

The configuration steps in this article are specific to Workbooks. For information about how you can use R and Python scripts to incorporate predictive modeling data into your flow, see [Use R and Python scripts in your flow](#) in the *Tableau Prep Help*.

Feature change history:

- 2021.2 — You can configure multiple analytics extension connections for each site. (You are limited to a single Einstein Discovery connection per site.)

For information about how to determine analytics extension usage in workbooks, see [Determining analytics extensions usage](#).

- 2021.1 — Einstein Discover is included as an analytics extension option. Einstein Discovery in Tableau is powered by [salesforce.com](#). Consult your agreement with [salesforce.com](#) for applicable terms.
- 2020.2 — You can configure a different analytics extension connection for each site on your server. Prior to this change a single analytics extension configuration applied globally to all sites on the server.
- 2020.1 — This functionality is now called *analytics extensions*. Previously the feature was called "external services."

Server SSL

To configure SSL for analytics extensions, you must install a valid certificate on the computer running Tableau Server. The certificate must be trusted by the computer running Tableau Server. The certificate Subject field or one of the SAN entries on must exactly match the URI of the analytics extensions service configuration.

Enable analytics extensions

Before you configure extensions, you must enable analytics extensions server-wide.

1. Sign in to the Tableau Server Admin Area.
 - If you only have a single site (default) on your server, click **Settings**, and then go to Step 2.
 - If you have multiple sites on your server:
 - a. Under **All Sites**, click **Manage all sites**.
 - b. Click the **Extensions** tab.
2. Scroll to **Analytics Extensions**, select **Enable analytics extensions**, and then click

Save.

Analytics Extensions

Enable and configure analytics extensions on this server. Analytics extensions allow you to extend Tableau dynamic calculations with programming languages like R and Python, and with other external tools and platforms. [Learn more](#)

☒ Enable analytics extensions

Configure analytics extensions settings

1. Sign in to the Tableau Server Admin Area.
2. On the Settings page, click the **Extensions** tab and then scroll to **Analytics Extensions**. (On multi-site deployments of Tableau Server, navigate to the site where you want to configure analytics extensions, and then click **Settings>Extensions**.)
3. **Multi-site deployments only:** you must enable Analytics Extensions on each site. Under Analytics Extensions, select **Enable analytics extensions for site**.
4. Under Analytics Extensions, click **Create new connection**.
5. In the **New Connection** dialog, click the connection type you want to add, then enter the configuration settings for your analytics service:

6. The options you need to configure depend on the connection type you choose:
- For an Einstein Discovery connection, click **Enable**.
 - For TabPy, RServer, and Analytics Extensions API connections, enter the following information:
 - **Connection Name** (Required): Specify the server type you are connecting to. RSERVER supports connections to R using the RServe package. TABPY supports connections to Python using TabPy, or to other analytics extensions.
 - **Require SSL** (Recommended): Select this option to encrypt the connection to the analytics service. If you specify a `HTTPS` URL in the **Host-name** field, then you must select this option.
 - **Hostname** (Required): Specify the computer name or URL where the analytics service is running. This field is case sensitive.
 - **Port** (Required): Specify the port for the service.

- **Sign in with a username and password** (Recommended): Select this option to specify user name and password that is used to authenticate to the analytics service.

7. Click **Create**.

Edit or delete an analytics extension connection

To edit or delete a configuration, navigate to **Analytics Extensions** on the **Extensions** tab of your site.

Click the **Edit** or **Delete** icon and follow the prompts to change the configuration.

Client requirement: Intermediate certificate chain for Rserve external service

As of Tableau Server version 2020.1, you must install a full certificate chain on Tableau Desktop computers (Windows and Mac) that are connecting to a Rserve external connection through Tableau Server. This requirement is due to how Rserve manages the handshake on secure connections.

Importing a root certificate on the Tableau Desktop is not sufficient, the entire certificate chain must be imported onto the client computer.

Script errors

Tableau cannot verify that workbooks that use an analytics extension will render properly on Tableau Server. There might be scenarios where a required statistical library is available on a

user's computer but not on the analytics extension instance that Tableau Server is using.

A warning will be displayed when you publish a workbook if it contains views that use an analytics extension.

This worksheet contains external service scripts, which cannot be viewed on the target platform until the administrator configures an external service connection.

Determining analytics extensions usage

Beginning with version 2021.2, analytics extensions configurations are mapped at the workbook level. This allows administrators to use custom views to query the Tableau Repository and determine which workbooks are using which extensions, and how often they are used.

To do this you need to join the workbook connections table to tables showing workbook usage. For details about creating and using custom administrative views, see [Collect Data with the Tableau Server Repository](#) and [Create Custom Administrative Views](#).

Table Extensions

Table Extensions allow you to create new data tables with an analytics extensions script. You can write a custom TabPy or Rserve script and optionally add one or more input tables. Table extensions are supported by Tableau Cloud, Tableau Server, and Tableau Desktop. This document focuses on Tableau Server.

Note: The data refreshes every time you open up a workbook or refresh a data source.

Benefits

Table Extensions have the following benefits for both new and experienced users.

- Faster data processing
- Low code editor
- Integrates with [Ask Data](#) and [Explain Data](#)

- Integrates with TabPy and Rserve
- Results can be used to construct dashboards or visualizations.

Prerequisites

Before you can use table extensions, you must complete the following list.

- Configure an analytics extension
 - For steps to configure analytics extension connections, see [Configure Connections with Analytics Extensions..](#)
- Publish your workbook.

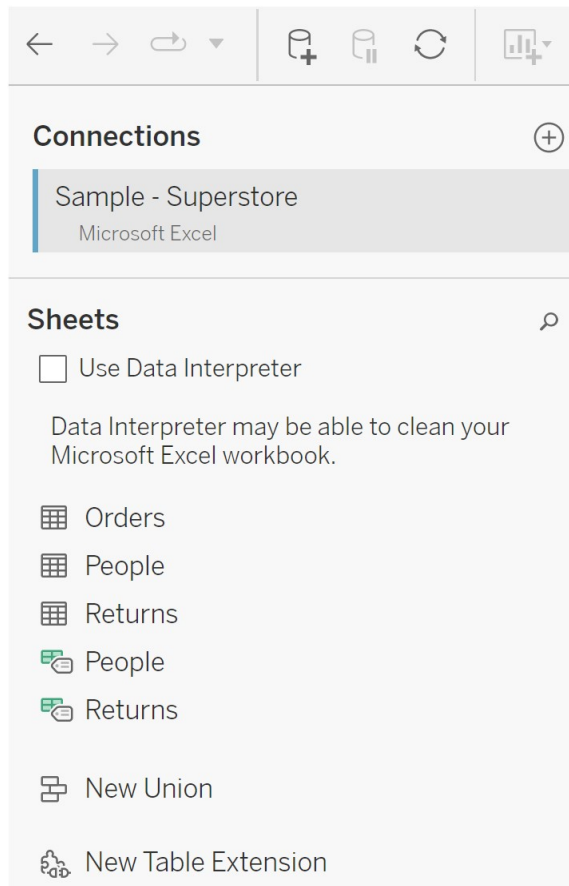

Create a Table Extension

To create a new table extension, complete the steps below.

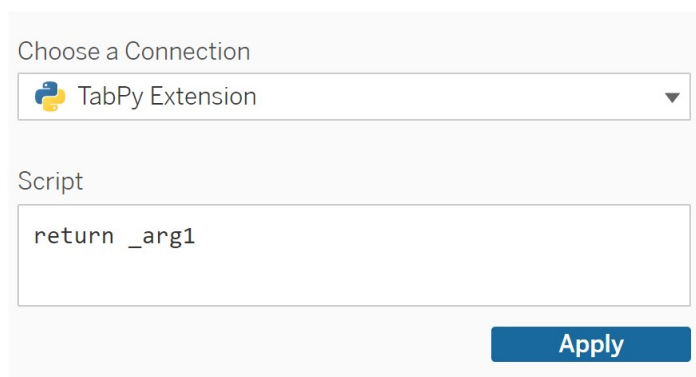

1. Open a published workbook.

Note: The workbook must be published before you can add a table extension.

2. Under **Sheets**, choose **New Table Extension**.

3. (Optional) Drag sheets into the table extension pane.
4. Under **Choose a Connection**, select an analytics extension.

5. In **Script**, enter your script.

6. Select **Apply**.
7. Choose **Update Now** and the results will appear in the **Output Table** tab.

				< Input Table Output Table	
Name Table Extension test					
Fields					
	Type	Field Name	Phys...	Rem...	
	Abc	Catego...	Tablea...	Categ...	
	🌐	City	Tablea...	City	
	🌐	Countr...	Tablea...	Count...	
				Category	City
				Office Supplies	Houston
				Office Supplies	Naperville
				Office Supplies	Naperville
				Office Supplies	Naperville
				Office Supplies	Philadelphia

8. In the **Name** field, enter a unique name for your new table extension.
9. Go to the sheet tab and publish the workbook to save it.

Note: If you edit the input table you have to press **Apply** again before you can see or use the updated output table data.

Troubleshooting tip: If your table extension is hitting an error, try using the circular **Refresh Data Source** button, located next to the **Save** button.

Table Extensions vs Analytics Extensions

Tableau has a few different features with "extension" in the name. While some of these products aren't related, table extensions and analytics extensions are. The table extensions feature relies on a connection with a analytics extensions to work. Let's break down each feature.

Table Extensions

The table extensions feature lets you create workbook calculations that send data and a processing script to your analytics extension. The returned results are displayed as a table on the Data Source tab and as measures and dimensions in the workbook.

Analytics Extensions

The analytics extensions feature allows you to extend Tableau dynamic calculations with programming languages like Python, external tools, and external platforms. After you create a connection to an analytics extension, you can communicate with your external server through calculated fields. For more information, see [Configure Connections with Analytics Extensions](#).

Configure Einstein Discovery Integration

Beginning with version 2021.1.0, Tableau Server supports integration with Einstein Discovery, making Einstein Discovery predictions available to authors and viewers of workbooks and dashboards. Starting in version 2021.2.0, Einstein Discovery predictions is also now available when authoring flows on the web.

Einstein Discovery in Tableau is powered by [salesforce.com](#). Consult your agreement with [salesforce.com](#) for applicable terms.

To integrate Einstein Discovery with Tableau Server, there are several necessary configuration steps, including some in Tableau Server, and some in the Salesforce org running Einstein Discovery. This overview outlines these steps for Dashboard extensions, Analytics extensions, and Tableau Prep extensions, and provides links to specific topics with steps for completing the server configuration.

For details on how to use Einstein Discovery predictions in Tableau, including licensing and permission requirements, see [Integrate Einstein Discovery Predictions in Tableau](#) in the Tableau Desktop and Web Authoring Help. For information about adding predictions in flows, see [Add Einstein Discovery Predictions to your flow](#).

Einstein Discovery dashboard extensions

The Einstein Discovery dashboard extension allow workbook authors to surface real-time predictions in Tableau. The dashboard extension delivers predictions interactively, on-demand, using source data in a Tableau workbook and an Einstein Discovery-powered model deployed in Salesforce.

To configure Tableau Server for the Einstein Discovery dashboard extension you need to do the following:

1. In Tableau Server:
 - a. Enable saved OAuth tokens for data connections and extensions in Tableau Server. Allow Saved Access Tokens
 - b. Enable Dashboard extensions for the server. See: Manage Dashboard Extensions in Tableau Server
2. In Salesforce, in the organization running Einstein Discovery:
 - a. Configure CORS in Salesforce.com for Einstein Discover Integration in Tableau Server.
 - b. In Salesforce, in the organization running Tableau CRM, create a connected app. See Step 1: Create a Salesforce connected app.
3. In Tableau Server, configure server for saved SF OAuth credentials using information from the connected app. Step 2: Configure Tableau Server for Salesforce.com OAuth

Einstein Discovery analytics extensions

The Einstein Discovery analytics extension gives your users the ability to embed predictions directly in Tableau calculated fields. A table calc script requests predictions from a model deployed in Salesforce by passing its associated prediction ID and input data that the model requires. Use Model Manager in Salesforce to auto-generate a Tableau table calculation script, and then paste that script into a calculated field for use in a Tableau workbook.

To configure Tableau Server for either the Einstein Discovery analytics extension you need to do the following:

1. In Tableau Server:
 - a. Enable saved OAuth tokens for data connections and extensions in Tableau Server. Allow Saved Access Tokens
 - b. Enable analytics extensions for the server and configure a connection type. See: Configure Connections with Analytics Extensions
2. In Salesforce, in the organization running Einstein Discovery, create a connected app. See Step 1: Create a Salesforce connected app.
3. In Tableau Server, configure server for saved SF OAuth credentials using information from the connected app. Step 2: Configure Tableau Server for Salesforce.com OAuth

Einstein Discovery Tableau Prep extensions

Supported in Tableau Server and Tableau Cloud starting in version 2021.2.0

The Einstein Discovery Tableau Prep extension enables users to embed Einstein predictions directly in their flows when authoring flows on the web.

To configure Tableau Server or Tableau Cloud for the Einstein Discovery Tableau Prep extension you need to do the following:

1. In Tableau Server:
 - a. Enable saved OAuth tokens for data connections and extensions in Tableau Server. See [Allow Saved Access Tokens](#)
 - b. Enable Tableau Prep Extensions for the server. See [Enable Tableau Prep Extensions](#).
2. In Salesforce, in the organization running Einstein Discovery, create a connected app. See [Step 1: Create a Salesforce connected app](#).
3. In Tableau Server, configure server for saved SF OAuth credentials using information from the connected app. [Step 2: Configure Tableau Server for Salesforce.com OAuth](#)

Configure External Actions Workflow Integration

Note: External Actions in Tableau rely on functionality provided by Salesforce Flow. The feature sends your selected data to Salesforce Flow, which runs on separate Salesforce infrastructure. Use of Salesforce Flow and other Salesforce products and services is subject to your agreement with Salesforce.

For more information on how to use External Actions, see [Integrate External Actions](#).

Editions, site roles, and permissions requirements

To configure and use External Actions workflows, you and anyone who will be using workflows must have certain site roles and permissions in editions of Salesforce and Tableau that

support External Actions.

Product	Editions	Site Roles and Permissions
Tableau	Tableau Cloud, Tableau Desktop, or Tableau Server versions 2022.3 or later	<p>To create or edit a workflow: Creator or Explorer (can publish) site role, and permissions to edit and save workbooks (Linux Windows)</p> <p>To use a workflow: Any site role</p>
Salesforce	Essentials, Professional, Enterprise, Performance, Unlimited, or Developer edition (see Salesforce Editions)	<p>To create or edit a flow: Manage Flows permission</p> <p>To use a flow: Run Flows permission or Flow User setting on the user detail page or Override default behavior and restrict access to enabled profiles or permission sets setting in Flow node (See How Does Flow Security Work?)</p>

Deployment requirements for External Actions

To use the External Actions workflow extension, the Salesforce administrator must **create a connected app** in Salesforce for Tableau Server.

Also, the domain for the Tableau Server or Tableau Cloud site where the extension will be deployed must be added to the **Salesforce Cross-Origin Resource Sharing (CORS) allowlist**.

Turn External Actions On or Off

In Tableau 2022.3 and later, the Tableau External Actions feature is turned on by default. To turn off the feature, you can use the Tableau Services Manager (TSM) command line interface (CLI) or configure site-level settings.

Use the TSM CLI

Use the TSM CLI to set the value for the `vizqlserver.workflow_objects_enabled` configuration key to `tsm configuration set -k vizqlserver.workflow_`

Tableau Server on Windows Help

```
objects_enabled -v false.
```

After changing the configuration key value, be sure to apply the change using the `tsm pending-changes apply` command. If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there's no restart. You can suppress the prompt using the `--ignore-prompt` option, but this option doesn't change the restart behavior. If the changes don't require a restart, the changes are applied without a prompt. For more information, see [tsm pending-changes apply](#).

Modify Site-Level Settings

For more information on how to customize site-level settings in Tableau Server, see [Site Settings Reference](#).

Integrate Tableau with a Slack Workspace

Beginning with version 2021.3, Tableau Server and Tableau Cloud support integration with the Tableau App for Slack, so your team can collaborate-share Tableau snapshots, search for Tableau content, and receive notifications about Tableau data—right where they're working in a Slack workspace.

The Tableau App for Slack lets you connect your Tableau site with a Slack workspace. After it's enabled, Tableau users can:

- See notifications in Slack when teammates share content with them, when they're mentioned in a comment, or when data meets a specified threshold in a data-driven alert. If a site administrator in Tableau Cloud or a server administrator in Tableau Server enables notifications on a site, users can control which notifications they receive in Slack by configuring their [Account Settings](#).
- See a preview of a viz when a Tableau URL is pasted into Slack, allowing users to share data-related content with context directly in Slack.
- Search for Tableau views or workbooks in Slack DMs and channels.
- Access Recents and Favorites from the Tableau App for Slack.

For more information, see [Receive Notifications, Search, and Share Using the Tableau App for Slack](#).

Note: Some notifications preferences might not be available if the features are turned off for your site. For example, if the User Visibility setting is set to Limited, notifications are turned off. For more information, see [Site Settings Reference and Manage Site User Visibility](#).

To integrate Slack with your Tableau site, there are a few necessary configuration steps, including some in your Tableau site, and some in the Slack workspace you want to connect. This overview outlines these steps for both Tableau site administrators on Tableau Cloud or a Tableau Server Administrator on Tableau Server, and Slack workspace administrators.

Requirements

Enabling Tableau in Slack requires both a Slack workspace administrator and either a Tableau site administrator in Tableau Cloud, or a Tableau server administrator in Tableau Server.

Connect a Tableau Server site to a Slack workspace

A Tableau Server administrator can connect a Slack workspace to one Tableau Server site. Connecting your Tableau site to a Slack workspace consists of three tasks:

- **Slack workspace administrator:** Create a private Slack application on the Slack API platform.
- **Tableau server administrator:** Use the app information to add an OAuth client.
- **Tableau server administrator:** Connect your Tableau site to Slack.

Each Tableau site can connect to one Slack workspace per Tableau site. For information about creating Slack apps, see Slack's [Best practices and guidelines for Slack platform](#).

Note: If using a proxy server, make sure you've followed proxy settings guidance in [Configuring Proxies and Load Balancers for Tableau Server](#) before you begin.

Additionally, for **Windows**:

- Make sure that the Windows environment variables already have `http_proxy` and `https_proxy` specified. For more information and instructions on specifying environment variables, see [Configuring Proxies and Load Balancers for Tableau Server](#).
- Add the Slack domains [in this list](#) to the allowlist. For more information, see [Communicating with the Internet](#).

Step 1: Create a Tableau App for Slack

Slack workspace administrator:

1. Go to Slack's [API documentation](#) and select **Create New App**
2. Select **From Scratch**, then add an app name and the workspace for the app to exist within. Select **Create New App**.
3. Give your app a name and select a Slack workspace.
4. You'll be taken to the app's basic information settings. From here, you can modify the app's privileges, description, and more.
5. Select **Bots** from the Add features and functionality section, then select **Review Scopes to Add**.
6. Under Bot Token Scopes, add these scopes:
 - `chat:write`
 - `files:write`
 - `users:read`
 - `users:read.email`
7. Select **OAuth & Permissions** from the navigation menu.

Important: Opting in to token rotation for your Tableau App for Slack will cause notifications to stop working in Slack. Token rotation can't be removed after it's added.

8. Select **Add New Redirect URL**.
9. Add a fully qualified URL `https://<Tableau Server URL>/auth/add_oauth_token`
10. Select **Basic Information** from the navigation menu.
11. Give the Client ID, Client Secret, and Redirect URL to the Tableau server administrator.
12. Add the Tableau App for Slack into the Slack workspace by selecting Basic Information from the Settings menu, then **Install**.

Note: Administrators can share their app with other Slack workspaces by activating a distribution option. For more information, see [Manage Distribution](#) in Slack's documentation.

Step 2: Add an OAuth client to the Tableau site

Tableau server administrator:

The Tableau server administrator will add the OAuth client from the Slack workspace administrator, then connect the Tableau site to Slack.

1. Sign in to the site you'd like to connect to Slack. On the Settings page of your site, select the **Integrations** tab.

2. Under Slack Connectivity, select **Add OAuth Client**.
3. Add the **Client ID**, **Client Secret**, and **Redirect URL** from the Slack workspace administrator, then select **Add OAuth Client** in the dialog.
4. The connection type and Client ID will appear in the table.

Step 3: Finalize the connection

Tableau server administrator:

When the OAuth client is added under Slack Connectivity:

1. Select **Connect to Slack**.
2. Follow the prompt to sign in to your Slack workspace.
3. Select **Allow** to give your Tableau site access to the Slack workspace.

The Tableau site and Slack workspace are now connected. In the Slack workspace, licensed Tableau users can receive Slack notifications when someone shares Tableau content, when a data-driven alert is triggered, or when someone is @mentioned in a comment on a view or workbook.

Disconnect a Tableau site from Slack

As a site admin, you can disconnect a Tableau site from a Slack workspace by selecting **Disconnect from Slack** in the **Integrations** tab of site settings. Users continue to receive notifications for some time. The OAuth client information you added in Step 2 is retained and can be used to connect to a new workspace, if needed.

As a Slack user, you can disconnect from Slack by selecting **Disconnect from Tableau** from the **Home** tab in the Tableau App for Slack.

Update your Tableau App for Slack

When a new version of the Tableau App for Slack is available, Tableau recommends updating the application to maintain app performance and use new features.

To update the Tableau App for Slack:

1. From the **Settings** page of your site, select the **Integrations** tab.

2. Under **Slack Connectivity**, select **Connect to Slack**.
3. Select **Update**.

Note: App updates applied by any Tableau admin affect all Tableau sites connected to the same workspace.

Troubleshoot the Tableau App for Slack

It's a best practice to [Manage app approvals for your Slack workspace](#). However, if your Slack workspace allows users who aren't admins to remove apps, it's possible that a user can remove the Tableau App for Slack for the site. In this scenario, other users will see the Tableau App for Slack, but its features won't work as expected. To resolve this issue, have your Slack admin uninstall and reinstall the Tableau App for Slack. Then, have your admin follow the steps to connect Slack with your Tableau site.

Creators: Connect to Data on the Web

Before you can create a workbook and build a view on the web to analyze your data on the web, you must connect to your data. Tableau supports connecting to data sources on the web published through Tableau Desktop, or, connecting to data directly through Tableau Cloud, Tableau Server, or Tableau Public.

Starting in 2019.3, Tableau Catalog is available as part of the Data Management offering for Tableau Server and Tableau Cloud. When Tableau Catalog is enabled in your environment, in addition to navigating and connecting to data from Explore, you can navigate and connect to more kinds of data, like databases and tables, from Tableau Catalog. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help. Starting in 2021.4, Data Management includes virtual connections, a central access point to data. For more information, see "About Virtual Connections and Data Policies" in the [Tableau Server](#) or [Tableau Cloud](#) help.

Open the Connect to Data page

On the web, you use the Connect to Data page to access data to connect to. After you sign in to Tableau Server or Tableau Cloud, you can open this page two ways:

- **Home > New > Workbook**
- **Explore > New > Workbook**

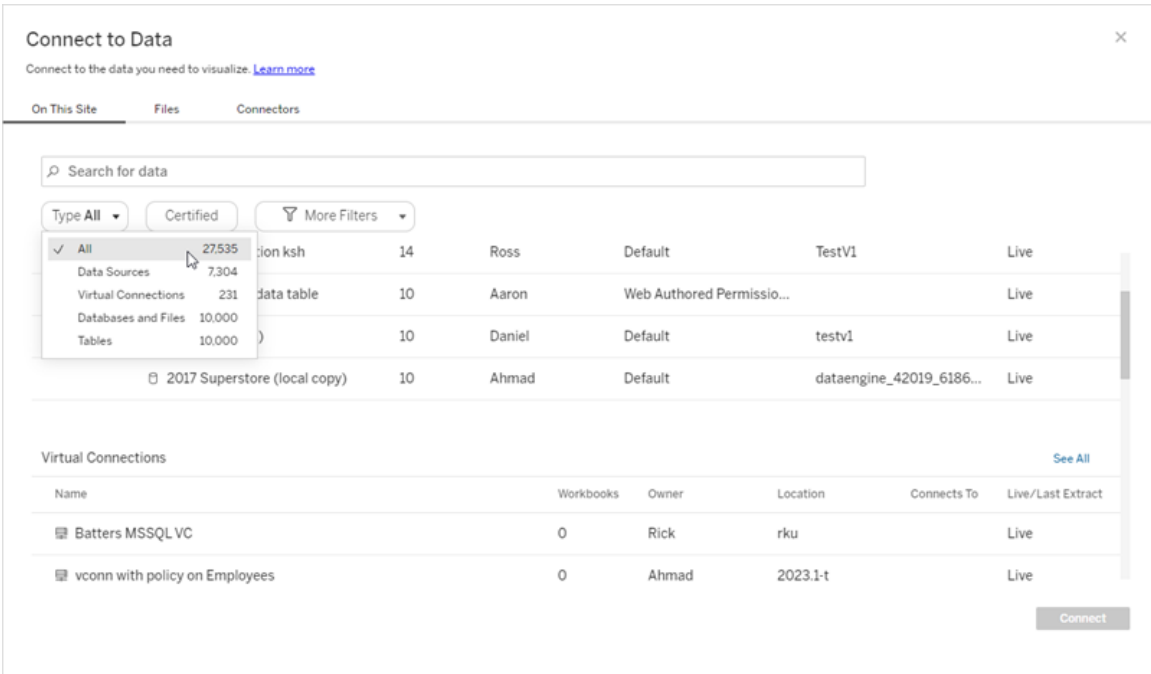

If you're on Tableau Public, you can open this page from your author profile:

- **My Profile > Create a Viz**

The **Connect to Data** dialog displays a scrollable list of mixed content that's popular. If you have a Data Management license, you can connect to data with a virtual connection, and if you have Data Management with Tableau Catalog enabled, you can also connect to external assets, like databases, files, and tables.

The responsive search field shows a list of suggestions that updates as you enter text. Filter search results by type of data, certification status, or other filters that depend on the type of data selected. For example, some types of data may allow you to filter based on tags,

connection type, data quality warnings, or other criteria. Older versions of the dialog look and function slightly differently, but the overall function is similar.

On the Connect to Data page, the tabs you see depend on the product you have.

Tableau Server

On Tableau Server, select from the following tabs to connect to data: On this site, Files, and Connectors.

Connect to data On this site

1. Select **On this site** to browse to or search for published data sources.
2. Select the data source under **Name** and click the **Connect** button.

Note: In addition to connecting to data sources, when you have Data Management, you can use **On this site** to connect to data using a virtual connection. When Tableau Catalog is enabled you can also connect to databases, files, and tables.

Connect to files

Tableau supports uploading Excel, text-based data sources (.xlsx, .csv, .tsv), and spatial file formats that only require one file (.kml, .geojson, .topojson, .json, and Esri shapefiles and Esri File Geodatabases packaged in a .zip) directly in your browser. In the **Files** tab of the **Connect to Data** pane, connect to a file by dragging and dropping it into the field or clicking **Upload from Computer**. The maximum file size you can upload is 1 GB.

Use connectors

From the **Connectors** tab, you can connect to data housed in a cloud database or on a server in your enterprise. You must supply connection information for each data connection that you make. For example, for most data connections, you must supply a server name and your sign-in information.

[Supported Connectors](#) has information on how to connect Tableau to each of these connector types to set up your data source. If the connector you need doesn't appear in the Connectors tab, you can connect to data through Tableau Desktop and publish your data source to Tableau Cloud or Tableau Server for web authoring. Learn more about how to [Publish a Data Source](#) in Tableau Desktop.

When Tableau successfully connects to your data, the Data Source page opens so that you can prepare the data for analysis and begin building your view. To learn more, see [Creators: Prepare Data on the Web](#).

***Teradata web authoring currently doesn't support query banding functionality. See [Teradata](#) for details.

‡Supports virtual connections if you have Data Management. See [About Virtual Connections and Data Policies](#) in the Tableau Server help for details.

Tableau Catalog Supported Connectors

Tableau Catalog supports making a connection with a subset of the data connectors that Tableau Server supports. If a data source, database, file, or table is grayed out, you can't connect from Tableau Server. You can, however, connect from the Tableau Desktop **Connect** pane, if you have the correct permissions.

Tableau Cloud

On Tableau Cloud, select from the following tabs to connect to data: On this site, Files, Connectors, and Dashboard Starters.

Connect to data On this site

1. Select **On this site** to browse to or search for published data sources.
2. Select the data source under **Name** and click the **Connect** button

Note: In addition to connecting to data sources, when you have Data Management, you can use **On this site** to connect to data using a virtual connection. When Tableau Catalog is enabled you can also connect to databases, files, and tables.

Connect to files

Tableau supports uploading Excel or text-based data sources (.xlsx, .csv, .tsv) directly in your browser. In the **Files** tab of the Connect to Data pane, connect to an Excel or text file by dragging and dropping it into the field or clicking **Upload from Computer**. The maximum file size you can upload is 1 GB.

Use connectors

From the **Connectors** tab, you can connect to data housed in a cloud database or on a server in your enterprise. You must supply connection information for each data connection that you make. For example, for most data connections, you must supply a server name and your sign-in information.

[Supported Connectors](#) has information on how to connect Tableau to your data using connectors. If the connector you need doesn't appear in the Connectors tab, you can connect to data through Tableau Desktop and publish your data source to Tableau Cloud or Tableau Server for web authoring. Learn more about how to [Publish a Data Source](#) in Tableau Desktop.

Note: If you're unable to connect to your data from Tableau Cloud, check to see if the database is publicly accessible. Tableau Cloud can only connect to data that's accessible from the public internet. If your data is behind a private network, you can connect using Tableau Bridge. To learn more, see [Publishers: Use Tableau Bridge to Keep Tableau Cloud Data Fresh](#).

**Teradata web authoring currently doesn't support query banding functionality. See [Teradata](#) for details.

Tableau Server on Windows Help

‡Supports virtual connections if you have Data Management. See [About Virtual Connections and Data Policies](#) in the Tableau Cloud help for details.

§Tableau Cloud doesn't support SSL using Google Cloud SQL.

Tableau Catalog Supported Connectors

Tableau Catalog supports making a connection with a subset of data connectors that Tableau Cloud supports. If a data source, database, file, or table is grayed out, you can't connect from Tableau Cloud. You can, however, connect from the Tableau Desktop **Connect** pane, if you have the correct permissions.

Use Dashboard Starters

On Tableau Cloud, you can author and analyze data from LinkedIn Sales Navigator, Oracle Eloqua, Salesforce, ServiceNow ITSM, and QuickBooks Online using Dashboard Starters. On the **Dashboard Starter** tab, from the list of pre-built designs, select an option and click **Use Dashboard**. See [Dashboard Starters for Cloud-based Data Sources](#) for details.

Tableau Public

On Tableau Public, you can connect to data by uploading a supported file.

Connect to files

Tableau supports uploading Excel or text-based data sources (.xlsx, .csv, .tsv) directly in your browser. In the **Files** tab of the Connect to Data pane, connect to an Excel or text file by dragging and dropping it into the field or clicking **Upload from Computer**. The maximum file size you can upload is 1 GB.

If you don't have a data set, check out the free [sample data sets](#) on the Tableau Public website.

Use connectors

From the **Connectors** tab, you can connect to data housed in a cloud database. You must supply connection information for each data connection that you make. For example, for most data connections, you must supply your sign-in information.

Supported Connectors has information on how to connect Tableau to your data using connectors. If the connector you need doesn't appear in the Connectors tab, you can connect to data through Tableau Desktop and create an data extract.

Note: If you're unable to connect to your data from Tableau Public, check to see if the database is publicly accessible. Tableau Public can only connect to data that's accessible from the public internet.

Tableau Public Connectors

Google Drive

OData

After you connect

When Tableau connects to your data, the Data Source page opens so that you can prepare the data for analysis and begin building your view. To learn more, see [Creators: Prepare Data on the Web](#).

Keep data fresh in web authoring

Update uploaded files in Tableau Cloud or Tableau Server: If you manually upload a file (Excel or text) for web authoring, Tableau can't refresh the file automatically. To update your data, select "Edit Connection" to upload a new version of the file.

In Tableau Public, go to your viz and click **Request Update**. You can also keep your data fresh automatically by selecting "Keep this data in sync" in Tableau Desktop Public Edition.

Update file-based published data sources in Tableau Cloud: If you have a published data source in Tableau Cloud (published through Tableau Desktop) that uses file-based data, you can keep it fresh using Tableau Bridge. For more information, see [Expand Data Freshness Options by Using Tableau Bridge](#).

Run Initial SQL

Note: Tableau Prep Builder version 2019.2.2 and later supports using Initial SQL, but doesn't yet support all of the same options supported by Tableau Desktop. For information about using Initial SQL with Tableau Prep Builder, see [Use Initial SQL to query your connections](#) in the Tableau Prep Builder Salesforce Help.

When connecting to some databases, you can specify an initial SQL command that will run or use a cached value when a connection is made to the database, for example, when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server.

Note: Initial SQL is different than a custom SQL connection. A custom SQL connection defines a relation (or table) to issue queries against. For more information, see [Connect to a Custom SQL Query](#).

You can use this command to:

- Set up temporary tables to use during the session.
- Set up a custom data environment.

You have the option to add an initial SQL command in the Server Connection dialog box or on the Data Source page.

Note: If your data source supports running an initial SQL statement, an **Initial SQL** link appears in the lower-left corner of the Server Connection dialog box. For information about your data source, see [Supported Connectors](#).

To use initial SQL

1. In the Server Connection dialog box, click **Initial SQL**. Or, on the Data Source page, select **Data > Initial SQL** or **Data > Query Banding and Initial SQL** depending on the database you connect to.
2. Enter the SQL command into the Initial SQL dialog box. You can use the **Insert** drop-down menu to pass parameters to your data source.

Note: Tableau doesn't examine the statement for errors. This SQL statement is sent to the database when you connect.

Your software license may restrict you from using initial SQL with your connection. If you publish to Tableau Server, the server must be configured to allow Initial SQL statements. By

default, the server software is configured to allow these statements to run when the workbook is loaded in a web browser.

Administrators can configure the server to ignore initial SQL statements by using the `tsm configuration set` command:

```
tsm configuration set -k vizqlserver.initialsql.disabled -v true
```

If the server doesn't allow initial SQL statements, the workbook opens, but the initial SQL commands aren't sent.

For more information about the `tsm configuration set` command, see the [Tableau Server Help](#).

Parameters in an initial SQL statement

You can pass parameters to your data source in an initial SQL statement. The following list has several benefits of using parameters in a initial SQL statement.

- You can configure impersonation using the **TableauServerUser** or **Tableau-ServerUserFull** parameters.
- If your data source supports it, you can set up row-level security (for example, for Oracle VPD or SAP Sybase ASE) to make sure that users see only the data that they're authorized to see.
- You can provide more details in logging, for example, the Tableau version or the workbook name.

The following parameters are supported in an initial SQL statement:

Parameter	Description	Example of returned value
TableauServerUser	The username of the current server user. Use when setting up impersonation on the server. Returns an	jsmith

	empty string if the user isn't signed in to Tableau Server.	
TableauServerUserFull	The username and domain of the current server user. Use when setting up impersonation on the server. Returns an empty string if the user isn't signed in to Tableau Server.	domain.lan\jsmith
TableauApp	The name of the Tableau application.	Tableau Desktop Professional Tableau Server
TableauVersion	The version of the Tableau application.	9.3
WorkbookName	The name of the Tableau workbook. Use only in workbooks with an embedded data source.	Financial-Analysis

Warning: Tableau Desktop doesn't include domain. You can include it if you aren't using delegation and you set tsm configuration set -k DelegationUseFullDomainName=-v true--force-keys

The following examples show different ways you can use parameters in an initial SQL statement.

- This example sets the security context on Microsoft SQL Server:

```
EXECUTE AS USER = [TableauServerUser] WITH NO REVERT;
```

- This example shows how, on a DataStax data source, you can use parameters to add detail to logging or to set up a session variable to track the data:

```
SET TABLEAUVERSION [TableauVersion];
```

- This example can be used to help set up row-level security for Oracle VPD:

```
begin

    DBMS_SESSION.SET_IDENTIFIER([TableauServerUser]);

end;
```

Note: Oracle PL/SQL blocks require a trailing semicolon to terminate the block. Consult Oracle documentation for the proper syntax.

Defer execution to the server

You can defer an initial SQL statement so that it's executed only on the server. One reason to defer execution to the server is if you don't have permission to execute the commands that set up impersonation. Use `<ServerOnly>` tags to enclose the commands to be executed only on the server.

Example:

```
CREATE TEMP TABLE TempTable(x varchar(25));
INSERT INTO TempTable VALUES (1);
<ServerOnly>INSERT INTO TempTable Values(2);</ServerOnly>
```

Security and impersonation

When you use the **TableauServerUser** or **TableauServerUserFull** parameter in an initial SQL statement, you'll create a dedicated connection that can't be shared with other users. This can also restrict cache sharing, which can enhance security, but may also slow performance.

Troubleshoot 'create table' for MySQL and Oracle connections

For MySQL connections, tables aren't listed after using initial SQL to create a table

After you connect to MySQL and run an initial SQL statement, the tables might not show because of the way Tableau constructs the query.

```
CREATE TABLE TestV1.testtable77(testID int);
```

To resolve this issue, add `IF NOT EXISTS` to the SQL statement:

```
CREATE TABLE IF NOT EXISTS TestV1.TestTable(testID int);
```

For Oracle connections, using initial SQL to create a table causes Tableau to stall

After you connect to Oracle and run an initial SQL statement, Tableau is stalled with a spinning wheel because of the way Tableau constructs the query.

```
CREATE TABLE TEST_TABLE (TESTid int)
```

To resolve this issue, use the following SQL statement:

```
BEGIN
EXECUTE IMMEDIATE 'create table test_table(testID int)';
EXCEPTION
WHEN OTHERS THEN NULL;
END;
```

Create and Interact with Flows on the Web

Starting in version 2020.4, you can create and interact with flows on Tableau Server to clean and prepare your data. Connect to your data, build a new flow, or edit an existing flow and your work is automatically saved every few seconds as you go. Create draft flows that are only available to you or publish your flow to make it available for others. Run your individual flows right from the web or run your flows automatically on a schedule using Tableau Prep Conductor if Data Management is licensed. For more information, see [Tableau Prep on the Web](#).

For more information about configuring the Tableau Prep Flow Authoring process on Tableau Server, see [Tableau Prep Flow Authoring](#).

Complete the tasks described in this article to enable web authoring for flows and other flow features on the web.

Turn flow web authoring on or off for a site

Enabled by default, this option controls whether users can create and edit flows on Tableau Server or Tableau Cloud

1. In a web browser, sign in to the server as an administrator, go to the site and click **Settings**.
2. In the **Web Authoring** section, clear or select **Flows. Let users edit flows in their browser.** to turn the functionality off or on.

3. If you want the change to take effect immediately, restart the server. Otherwise, the change takes effect after server session caching expires or the next time users sign in after signing out.

Enable linked tasks

Supported in Tableau Cloud and Tableau Server version 2021.3 and later.

Use the **Linked Tasks** option to schedule up to 20 flows to run sequentially, one after the other. Linked tasks can only be run on schedules with the **Linked Tasks** option selected. For more information about setting up linked tasks, see [Schedule linked tasks](#).

Starting in version 2022.1, **Linked Tasks** is enabled by default on the **Server Settings** and for any new flow schedules that you create. In prior versions, administrators must first enable the option.

If you have multiple sites, you can turn off **Linked Tasks** for individual sites by clearing the check boxes described below.

If the setting is turned off after linked tasks are scheduled, any tasks that are running will complete and the scheduled linked tasks are hidden and no longer show on the **Scheduled Tasks** tab.

Enable Linked Tasks (version 2021.4 and earlier)

1. In a web browser, sign in to the server as an administrator and go to the site in which you want to enable **Linked Tasks** for flows. In that site, click **Settings**.
2. In the **Linked Tasks** section, select **Let users schedule linked tasks** to enable administrators to configure schedules to run linked tasks.
3. Select **Let users run linked tasks manually using Run Now** to enable users to run linked flow tasks using **Run Now**.

Enable flow parameters

Enable users to schedule and run flows that include parameters. Parameters enable users to scale their flows by building them once, then changing the parameter values to accommodate different data scenarios.

Parameters can be entered in an input step for file name and path, table name, or when using custom SQL queries, in an output step for file name and path and table name, and in any step type for filters or calculated values.

Starting in Tableau Prep Builder and Tableau Cloud version 2023.2, you can add system parameters to flow output names to automatically include the flow run start date and time.

Flow parameter settings can be applied at the server level to include all sites on Tableau Server. The settings can be disabled at the site level to include only specific sites.

For more information about using parameters in flows, see [Create and Use Parameters in Flows](#) in the Tableau Prep help.

1. In a web browser, sign in to the server as an administrator and go to the site in which you want to enable **Flow Parameters**. In that site, click **Settings**.
2. In the **Flow Parameters** section, select **Let users run and schedule flows that use parameters** to enable the functionality.
3. (version 2023.2 and later) Select **Allow system generated parameters like timestamps to be applied to output names** to enable users to add a date or time stamp to the flow output name at runtime for file and published data source output types.
4. Select **Allow parameters that can accept any input** to enable anyone running the flow to enter any parameter value in the flow at run time.

Important: Setting this option enables any flow user to enter any value in a parameter, potentially exposing data that the user should not have access to.

If this option is not selected, users can only select from predefined list of parameter values and any flows that include parameters that accept any value cannot be run or scheduled to run.

Enable Tableau Prep Conductor

If Data Management is licensed, enable this option to let users schedule and track flows in Tableau Server and Tableau Cloud. For information about the additional configuration

requirements for Tableau Prep Conductor, see [Tableau Prep Conductor](#).

1. In a web browser, sign in to the server as an administrator and go to the site in which you want to enable Tableau Prep Conductor. In that site, click **Settings**.
2. In the **Tableau Prep Conductor** section, select **Let users schedule and monitor flows** to enable the functionality.

Enable Run Now

Control whether users or only administrators can run flows manually using the **Run Now** option. Data Management is not required to run flows manually.

1. In a web browser, sign in to the server as an administrator and go to the site in which you want to enable Run Now for flows. In that site, click **Settings**.
2. In the **Run Now** section, select **Let users run jobs manually using Run Now** to enable the functionality.

Clear the check box if only Server Administrators can run flows manually.

Flow Subscriptions

Control whether users can receive flows notifications about scheduled tasks for successful flow runs. Data Management is required to enable notifications.

1. In a web browser, sign in to the server as an administrator and go to the site in which you want to enable flow subscriptions. In that site, click **Settings**.
2. In the **Flow Subscriptions** section, select **Let users send or receive emails that include flow output data** to enable the functionality.

Flow Subscriptions

Flow owners can schedule and send emails with flow output data to themselves and others. [Learn more](#)

☒ Let users send or receive emails that include flow output data

☐ Attach .csv and .xlsx flow output files. This option sends data outside of Tableau and is not recommended

Note: The option to attach either a .csv or .xlsx file type to the email is only available for on-premise environments.

Enable Tableau Prep Extensions

Supported in Tableau Server and Tableau Cloud starting in version 2021.2.0

Set this option to control whether users can connect to Einstein Discovery to run predictive models against data in their flow.

You can use Einstein Discovery-powered models to bulk score predictions for the data in your flow when authoring flows on the web. Predictions can help you make better informed decisions and take actions to improve your business outcomes.

You'll need to configure additional settings to include predictions in our flow. For more information, see [Add Einstein Discovery Predictions to your flow](#) and [Configure Einstein Discovery Integration](#).

1. In a web browser, sign in to the server as an administrator and go to the site in which you want to enable Tableau Prep Extensions. In that site, click **Settings > Extensions**.
2. In the **Tableau Prep Extensions** section, select **Let users connect to Einstein Discovery** to enable the functionality.

Turn autosave off or on

Enabled by default, this feature automatically saves a user's flow work every few seconds.

While not recommended, administrators can disable autosave on a site using the Tableau Server REST API method "Update Site" and `flowAutoSaveEnabled` setting. For more information, see [Tableau Server REST API Site Methods: Update Site](#). For more information about autosave on the web, see Turn autosave off or on.

For more information about configuring site settings, see [Site Settings Reference](#) in the Tableau Server help.

Tableau Prep on the Web

Internet Explorer 11 on Windows and compatibility mode for Internet Explorer is not supported.

Starting in version 2020.4, Tableau Prep supports web authoring for flows. Now you can create flows to clean and prepare your data using Tableau Prep Builder, Tableau Server, or Tableau Cloud. You can also manually run flows on the web and the Data Management is not required.

While most of the same Tableau Prep Builder functionality is also supported on the web, there are a few differences when creating and working with your flows.

Important: To create and edit flows on the web you must have a Creator license. Data Management is only required if you want to run your flows on a schedule using Tableau Prep Conductor. For more information about configuring and using Tableau Prep Conductor, see Tableau Prep Conductor in the [Tableau Server](#) or [Tableau Cloud](#) help.

Installation and Deployment

To enable users to create and edit flows on the web, you'll need to configure several settings on your server. For more information about each of these settings, see [Create and Interact with Flows on the Web](#).

- **Web Authoring:** Enabled by default, this option controls whether users can create and edit flows on Tableau Server or Tableau Cloud.
- **Run Now:** Controls whether users or only administrators can run flows manually using the **Run Now** option. The Data Management isn't required to run flows manually on the web.
- **Tableau Prep Conductor:** If Data Management is licensed, enable this option to let users schedule and track flows.
- **Tableau Prep Extensions** (version 2021.2.0 and later): Controls whether users can connect to Einstein Discovery to apply and run predictive models against data in their flow.
- **Autosave:** Enabled by default, this feature automatically saves a user's flow work every few seconds.

On Tableau Server, administrators can fine-tune the configuration of the Tableau Prep Flow Authoring processes. For more information, see [Tableau Prep Flow Authoring](#).

Sample data and processing limits

To maintain performance while working with flows on the web, limits are applied to the amount of data you can include in a flow.

The following limits apply:

- When connecting to files, the maximum file size is 1GB.
- The data sampling option to include all data is not available. The default sample data limit is 1 million rows.

- The maximum number of rows that a user can select when using large data sets is configured by the administrator. As a user, you can select the number of rows up to that limit. For more information, see [tsm configuration set Options](#).

For more information about setting your data sample, see [Set your data sample size](#) in the Tableau Prep help.

Available features on the web

When you create and edit flows on the web you may notice a few differences in navigation and the availability of certain features. While most features are available across all platforms, some features are limited or not yet supported in Tableau Server or Tableau Cloud. The following table identifies features where differences might apply.

Feature area	Exceptions	Tableau Prep Builder	Tableau Server	Tableau Cloud
Connect to Data	Some connectors may not be supported on the web. Open the Connect pane on your server to see supported connectors.	✓	✓	✓
Build and Organize your Flow		✓	✓	✓
Set your data sample size	In Tableau Server and Tableau Cloud, the data sample size is subject to limits set by your administrator	✓	✓	✓
Union files and database tables in the input step	Input unions can't be edited or created in Tableau Server or Tableau Cloud. Only in Tableau Prep Builder.	✓	✓	✓
Clean and		✓	✓	✓

Tableau Server on Windows Help

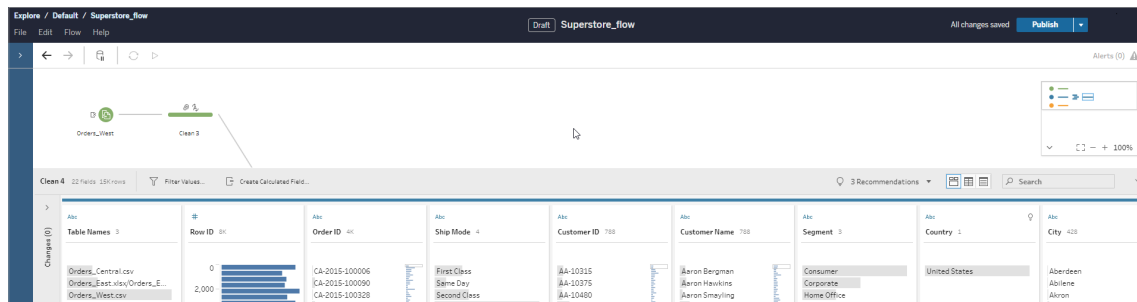

Shape Data				
Copy data grid values	Available in Tableau Prep Builder and Tableau Server starting in version 2022.3 and Tableau Cloud starting in 2022.2 (August)	✓	✓	✓
Aggregate, Join, or Union Data		✓	✓	✓
Use R and Python Scripts in your Flow	Script steps can't be added when creating or editing a flow in Tableau Cloud. This is currently supported only in Tableau Prep builder and Tableau Server.	✓	✓	✗
Create reusable flow steps		✓	✗	✗
Automatically save your flows on the web		Not Applicable	✓	✓

Create an extract to a		✓	✗	✗

Microsoft Excel worksheet				
Connect to a Custom SQL Query		✓	✓	✓
Create a published data source		✓	✓	✓
Save flow output to external databases		✓	✓	✓
Add Einstein Discovery Predictions to your Flow		✓	✓	✓

Autosave and working with drafts

When you create or edit flows on the server, your work is automatically saved as a draft every few seconds so that in the event of a crash, or when closing a tab by accident, you don't lose your work.

Drafts are saved to the server and project you are signed into. You can't save or publish a draft to another server, but you can save the flow to another project on that server using the **File > Publish As** menu option.

Draft content can only be seen by you until you publish it. If you publish changes and need to revert them, you can use the **Revision History** dialog to view and revert to a previously published version. For more information about saving flows on the web, see [Automatically save your flows on the web](#).

Publishing flows on the web

Whether you create a flow from scratch on the web or edit an existing flow, before you can run the flow you'll need to publish it.

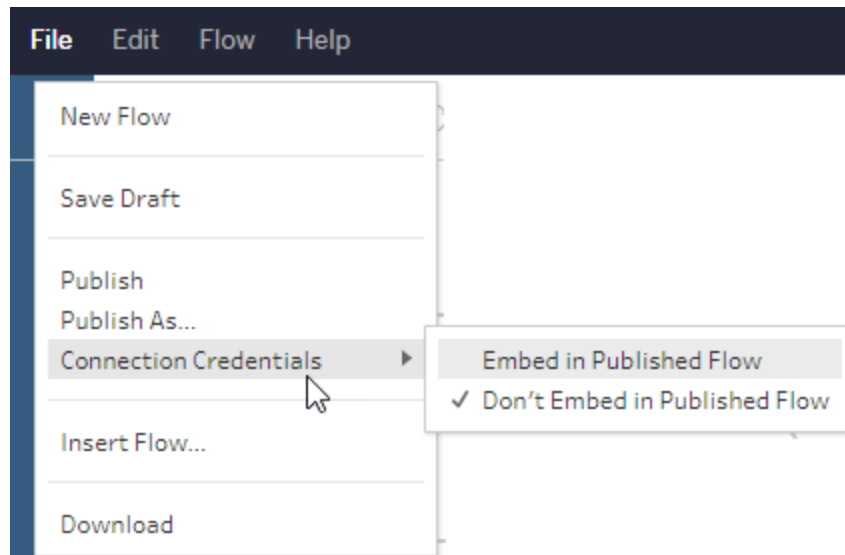

- You can only publish draft flows to the same server you are signed into.
- You can publish a draft to a different project using the **File** menu and selecting **Publish As**.
- You can embed credentials for your flow's database connections to enable the flow to run without having to manually enter the credentials when the flow runs. If you open the flow to edit it, you'll need to re-enter your credentials.

Embed credentials

Embedding credentials only applies to running flows on your server. Currently, you will manually need to enter your credentials when editing a flow connected to a database. Embedding credentials can only be set at the flow level and not at the server or site level.

Do one of the following:

- From the top menu, select **File > Connection Credentials > Embed in Published Flow**.

- When publishing a flow, select the **Embed credentials** check box. This option shows when you select **Publish As** to publish the flow to a new project for the first time or when you are editing a flow that was last published by someone else.

Publish a flow

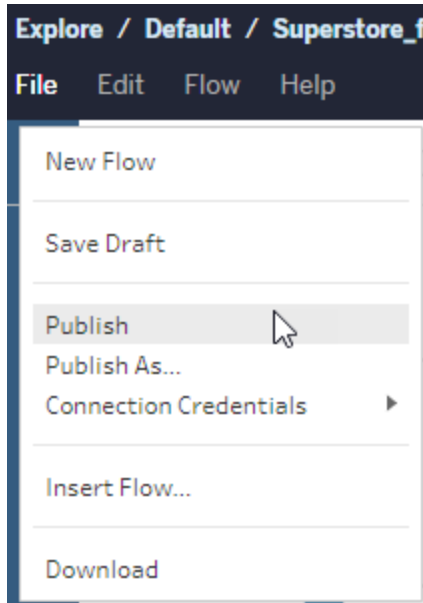

When you publish your flow, it becomes the current version of the flow and can be run and seen by others who have access to your project. Flows that are never published or flow

Tableau Server on Windows Help

changes that you make to a draft can only be seen by you until you publish the flow. For more information about flow statuses, see [Automatically save your flows on the web](#).

To publish your flow, do one of the following:

- From the top menu, select **File > Publish** or **File > Publish As**

- From the top bar, click the **Publish** button or click the drop arrow to select **Publish As**.

Who can do this

- Server Administrator, Site Administrator Creator, and Creator allow full connecting and publishing access.
- Creator can perform web authoring tasks.

Create, Interact with, and Embed Views on the Web

You can create and interact with views on Tableau Server. For more information, see the following topics in the Tableau Help for users.

[Using Tableau on the Web](#)

[Tour your Tableau Site](#)

[Edit Views on the Web](#)

[Join your Data](#)

[Make Workbooks Compatible Between Versions](#)

Alerts and subscriptions

[Troubleshoot Subscriptions](#)

[Send Data-Driven Alerts from Tableau Cloud or Tableau Server](#)

Manage Saved Credentials for Data Connections

Saved credentials enable you to connect to a data source without being prompted for your credentials. The credentials saved for your connection can be OAuth access tokens, or other credentials, such as user name and password. You can manage saved credentials on your account settings page.

On Tableau Server, if your server administrator has allowed you to save credentials, you can find and manage them in the **Saved Credentials** section on your My Account Settings page.

Notes:

- If you don't see the Saved Credentials section, consult with your admin about allowing saving credentials.
- When editing Tableau Prep flows on the web, you may still be prompted to reauthenticate.

Test connections using saved credentials

If the connector supports test functionality, you can test the connection using saved credentials.

1. While you're signed in to Tableau Server or Tableau Cloud, display your Account Settings page.
2. In the Saved Credentials section, select the **Test** link next to the stored connection that you want to test.

This test confirms that Tableau Cloud or Tableau Server can access your account using this corresponding saved credential. If the test succeeds, but you can't access your data through this managed connection, confirm that the credentials you provided for this connection can access your data.

For example, if you accidentally created the connection using your personal Gmail account, but you use a different account to access a Google Analytics database, you'll need to delete the saved credentials and sign in to the data using the appropriate Gmail account.

Update saved credentials

To help ensure uninterrupted data access from existing Tableau content after a custom OAuth client has been configured for your site, we encourage you to update your saved credentials. To update saved credentials, you can delete the previous saved credentials for a particular connector and then add it again.

When you add saved credentials again, both new and existing Tableau content will access the data using the custom OAuth client configured by your server administrator. For more information about custom OAuth clients, see [Configure custom OAuth for a site](#).

1. Sign in to Tableau Server and navigate to your **My Account Settings** page.
2. Under **Saved Credentials for Data Sources**, do the following:
 1. Click **Delete** next to the saved credentials for a connector.
 2. Next to the same connector, click **Add** and follow the prompts to 1) connect to the custom OAuth client that your site admin notified you about and 2) save the latest credentials.

Clear all saved credentials

When you select **Clear All Saved Credentials**, the following items are removed from your user account:

- All saved credentials for connections that are stored in your account.

Caution: If any of these saved credentials are stored with published workbooks or data sources, deleting them also removes access to the data source from those locations. Effectively, this is like "changing the locks" anywhere the affected saved credentials are used.

- Passwords you've used to access published data extracts or workbooks that connect to them.

Remove saved credentials

To remove Tableau access to data, delete the associated saved credentials for that data from your account. After you delete the credentials, you'll need to sign in to the data the next time you access it. This creates new saved credentials.

Your administrator might choose for all users to use the same shared credentials for connecting to a data source. If this is the case, the saved credential is associated with the data connection for all users, and it doesn't appear under Saved Credentials on your Account Settings page.

Note: If you're a Tableau Server user and can't delete saved credentials, ask your administrator if they've cleared the Allow users to save data source access tokens option in the server settings.

Create and Edit Private Content in Personal Space

Personal Space is a private location for all Explorers and Creators to save content to when working in a Tableau Site. Content saved in Personal Space can't be shared with other users but can be moved to a project when you're ready for others to see it. Within Personal Space, you can create a new workbook or save a workbook to Personal Space as a separate copy. You can also move existing content you own into Personal Space for editing, then move it back to a project later. Explorers can download workbooks in Personal Space, including all data included in the workbook.

Privacy in Personal Space

Content saved to your Personal Space is only visible to you and site administrators. Site administrators can't directly access any user's Personal Space or edit content in someone else's Personal Space, but they can view and manage Personal Space workbooks. Personal Space workbooks appear in administrator search results and as a workbook location on the Explore page. In addition, the permissions menu is unavailable when a workbook is in Personal Space because the workbook is private.

Tableau Catalog and Personal Space

Starting in 2019.3, Tableau Catalog is available with Data Management in Tableau Server and Tableau Cloud. For more information, see "About Tableau Catalog" in the Tableau Server or Tableau Cloud Help.

When Tableau Catalog is enabled in your work environment, the information about workbooks you save in your Personal Space is indexed by Catalog. These workbooks are included in lineage counts, however, only you can see the workbooks. Furthermore, users who browse through the lineage tool see Permissions required instead of information about workbooks in your Personal Space.

Collaboration tools

When a workbook is in Personal Space, some functionality is disabled, including share, metrics, comments, alerts, and subscriptions. Existing alerts and subscriptions to you will continue running, but alerts and subscriptions to others will fail, since the content is now private. Metrics can't be created in Personal Space but will continue to work if a connected workbook is moved there.

These limitations are removed when the workbook is moved or saved to another location. For example, if a workbook contains comments and moves to Personal Space, existing comments are hidden. Comments restore when the workbook is moved to another location.

Extract refreshes in Personal Space

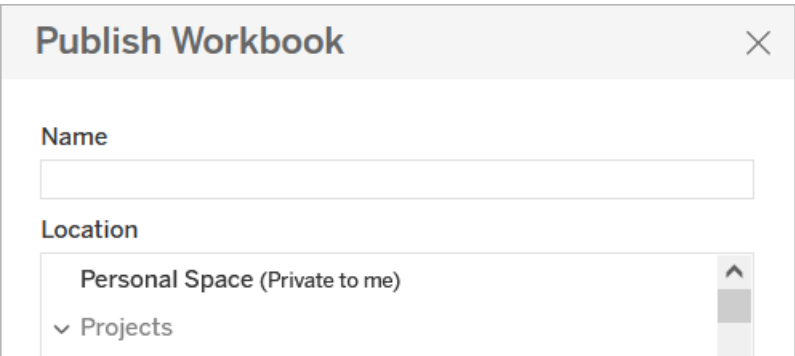

To limit resource consumption, existing extract refreshes continue to run if they've been scheduled, but new extract refreshes can't be scheduled while a workbook is in Personal Space.

Find content in Personal Space

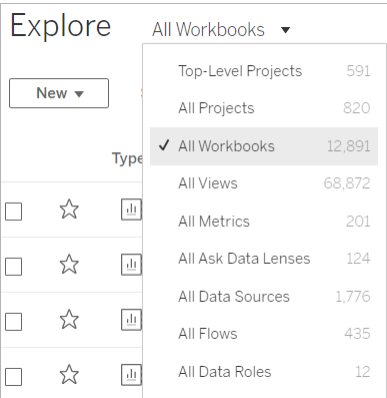

You can access Personal Space from the left navigation menu to see all your Personal Space content or create a new workbook, and you can save to Personal Space when creating or

Tableau Server on Windows Help

editing a workbook anywhere on the site.

You can also see workbooks in Personal Space from the Explore page when All Workbooks is selected, and you can filter down to Personal Space content.

Publish a workbook to Personal Space

Personal Space works much like a private project for you to publish a new or existing workbook to from Tableau Cloud, Tableau Server, or Tableau Desktop.

Publish a workbook to Personal Space on Tableau Server or Tableau Cloud

1. With the workbook open, select **File > Publish As**.
2. Under Location, select **Personal Space**.

Note: Explorers can only save workbooks to Personal Space and may not see a location selection dialog.

Publish a workbook to Personal Space from Tableau Desktop

Starting in 2023.1, you can publish a workbook to Personal Space from Tableau Desktop.

1. With the workbook you want to publish open in Tableau Desktop, select **Server > Publish Workbook**.
2. Under Project, select **Personal Space**.
3. Under Data Sources, select **Edit**.

4. In the Manage Data Sources popup under Publish type, select **Embedded in workbook** for all data sources. You must embed data sources when publishing from Tableau Desktop, because you can't publish data sources separately to Personal Space.
5. Fill out the remainder of the publishing options as usual. For more information, see [Comprehensive Steps to Publish a Workbook](#).

Move workbooks to Personal Space

You can move an existing workbook to Personal Space if you are the owner of the workbook and there is room in your Personal Space. Personal Space storage limits are set by administrators.

To move a workbook to Personal Space:

- Select a workbook, then click the **Actions** drop-down menu.
- Select **Move**.
- Under Location, Select **Personal Space**.

Note: Explorers can only save workbooks to Personal Space and may not see the move action or location selection dialog.

For more information, see [Perform actions](#) in the Manage Web Content help topic.

When you move an existing workbook or data source to Personal Space, tools like share, alerts, and subscriptions become hidden. Existing extract refreshes continue to run if they've been scheduled, but users can't schedule new extract refreshes within their Personal Space.

Existing subscriptions and alerts also continue but can't be edited from Personal Space and will fail if other users are recipients. Existing connected metrics will continue to refresh, but the connected view will not be visible to other users.

Move workbooks from Personal Space

When you move a workbook out of Personal Space, collaboration tools like share, alerts, and subscriptions become visible, and any existing comments reappear.

Use Relationships for Multi-table Data Analysis

Tables that you drag into this canvas use relationships. Relationships are a flexible way to combine data for multi-table analysis in Tableau.

Think of a relationship as a contract between two tables. When you are building a viz with fields from these tables, Tableau brings in data from these tables using that contract to build a query with the appropriate joins.

We recommend using relationships as your first approach to combining your data because it makes data preparation and analysis easier and more intuitive. [Use joins only when you absolutely need to](#). Learn more about the basics of creating relationships in this 5-minute video.

Note: The interface for editing relationships shown in this video differs slightly from the current release but has the same functionality.

Learn more about how relationships work in these Tableau blog posts:

- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)
- [Relationships, part 3: Asking questions across multiple related tables](#)

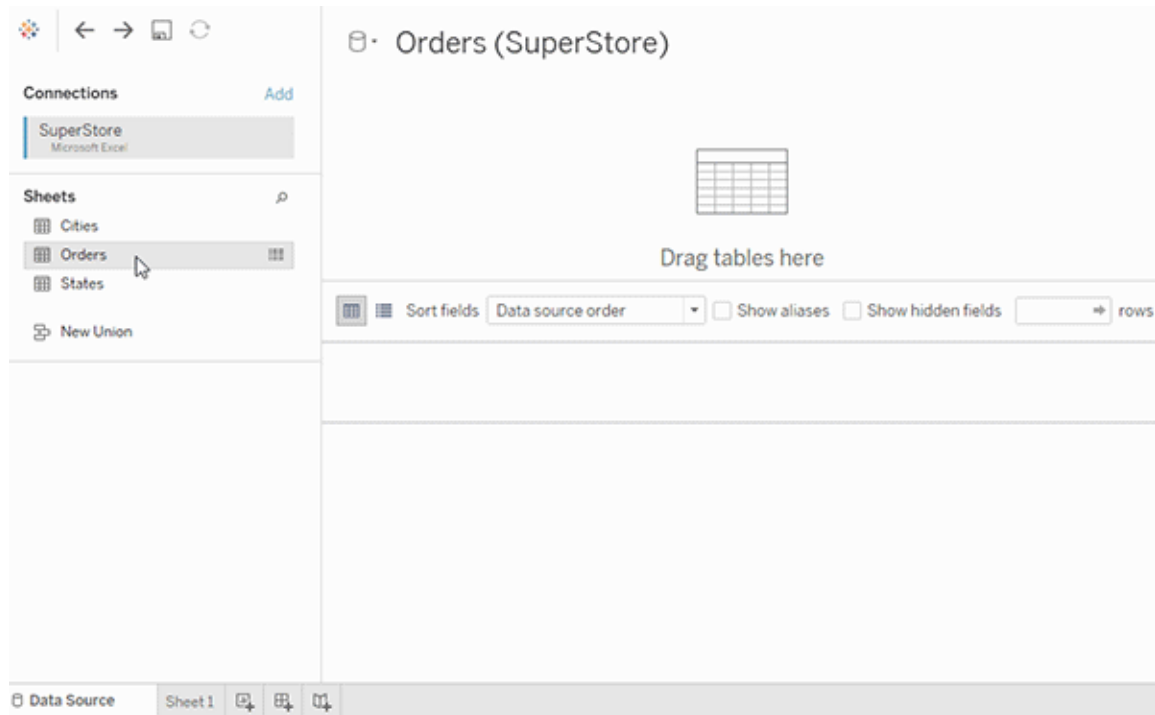

Also see video podcasts on relationships from [Action Analytics](#), such as [Why did Tableau Invent Relationships?](#) Click "Video Podcast" in the [Library](#) to see more.

Are you building a new data source and workbook?

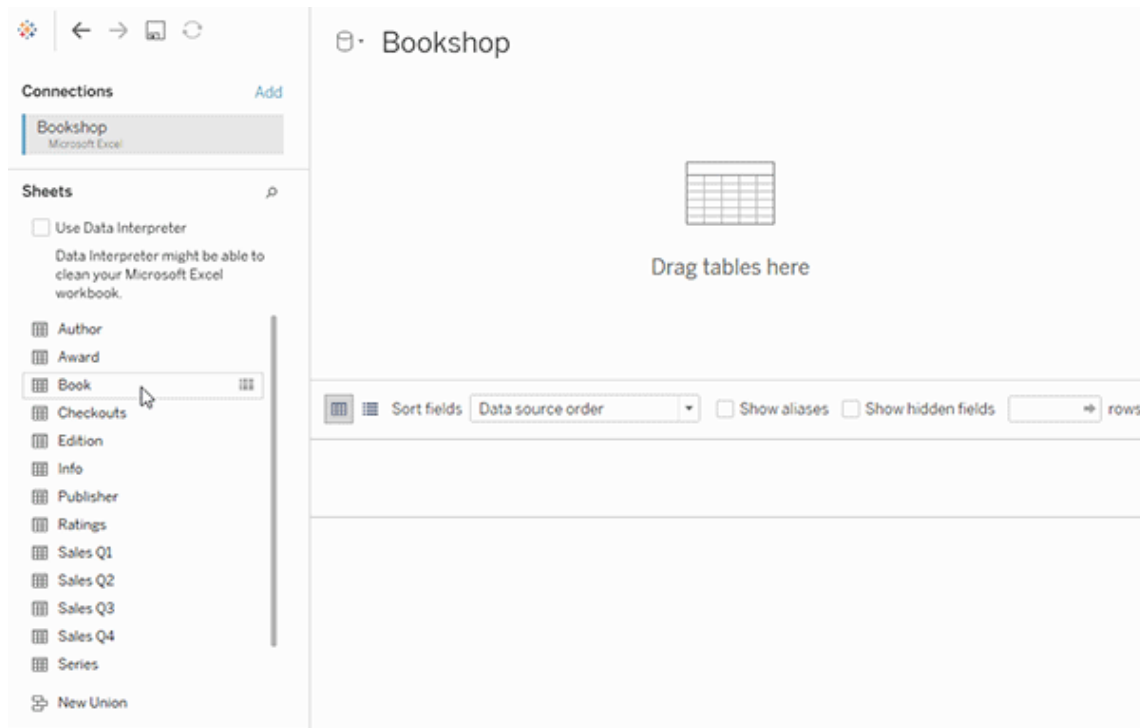

Tableau Server on Windows Help

Drag a table to the Data Source page canvas to start building your data source.

A data source can be made of a single table that contains all of the dimension and measure fields you need for analysis...

Or, you can create a multi-table data source by dragging out more tables and defining their relationships...

Watch this 1-minute video about getting started with using relationships.

Note: The interface for editing relationships shown in this video differs slightly from the current release but has the same functionality.

For more information about using relationships, see [Relate Your Data](#), [How Relationships Differ from Joins](#), [The Tableau Data Model](#), and [Create and define relationships](#).

For more information on changes to data sources and analysis in Tableau 2020.2, see [What's Changed with Data Sources and Analysis in 2020.2](#) and [Questions about Relationships, the Data Model, and Data Sources in 2020.2](#).

Are you opening an older workbook or data source?

Tableau Server on Windows Help

When you open a pre-2020.2 workbook or data source in 2020.2, your data source will appear as a single logical table in the canvas, with the name "Migrated Data" or the original table name. Your data is preserved and you can continue to use the workbook as you did before.

To see the physical tables that make up the single logical table, double-click that logical table to open it in the physical layer. You will see its underlying physical tables, including joins and unions.

For more information on changes to data sources and analysis in Tableau 2020.2, see [What's Changed with Data Sources and Analysis in 2020.2](#) and [Questions about Relationships, the Data Model, and Data Sources in 2020.2](#).

The Tableau Data Model

Every data source that you create in Tableau has a data model. You can think of a data model as a diagram that tells Tableau how it should query data in the connected database tables.

The tables that you add to the canvas in the **Data Source** page create the structure of the data model. A data model can be simple, such as a single table. Or it can be more complex, with multiple tables that use different combinations of relationships, joins, and unions.

The data model has two layers:

- The default view that you first see in the Data Source page canvas is the *logical layer* of the data source. You combine data in the logical layer using relationships (or noodles). Think of this layer as the Relationships canvas in the Data Source page. For more information, see [Use Relationships for Multi-table Data Analysis](#).
- The next layer is the *physical layer*. You combine data between tables at the physical layer using **joins** and unions. Each logical table contains at least one physical table in this layer. Think of the physical layer as the Join/Union canvas in the Data Source page. Double-click a logical table to view or add joins and unions.

Logical Layer

Noodles = Relationships

Physical Layer

Venn diagram = Joins

The top-level view of a data source with multiple, related tables. This is the logical layer. Logical tables can be combined using relationships (noodles). They don't use join types. They act like containers for physical tables.

Double-click a logical table to open it and see its physical tables. Physical tables can be combined using joins or unions. In this example, the Book logical table is made of three, joined physical tables (Book, Award, Info).

Logical Layer	Physical Layer
Relationships canvas in the Data Source page	Join/Union canvas in the Data Source page
Tables that you drag here are called logical tables	Tables that you drag here are called physical tables
Logical tables can be related to other logical tables	Physical tables can be joined or unioned to other physical tables
Logical tables are like containers for physical tables	Double-click a logical table to see its physical tables
Level of detail is at the row level of the logical table	Level of detail is at the row level of merged physical tables
Logical tables remain distinct (normalized), not merged in the data source	Physical tables are merged into a single, flat table that defines the logical table

Layers of the data model

The top-level view that you see of a data source is the **logical layer** of the data model. You can also think of it as the Relationships canvas, because you combine tables here using relationships instead of joins.

When you combine data from multiple tables, each table that you drag to the canvas in the logical layer must have a relationship to another table. You do not need to specify join types for relationships; during analysis Tableau automatically selects the appropriate join types based on the fields and context of analysis in the worksheet.

The **physical layer** of the data model is where you can combine data using joins and unions. You can only use pivots in this canvas. You can think of it as the Join/Union canvas. In previous versions of Tableau, the physical layer was the only layer in the data model. Each logical table can contain one or more physical tables.

Important: You can still create single-table data sources in Tableau that use joins and unions. The behavior of single-table analysis in Tableau has not changed. Your upgraded workbooks will work the same as they did before 2020.2.

Learn more: For related information on combining data using relationships, also see these topics and blog posts:

Understanding the data model

In previous versions of Tableau, the data model had only the physical layer. In Tableau 2020.2 and later, the data model has the logical (semantic) layer and a physical layer. This gives you more options for combining data using schemas to fit your analysis.

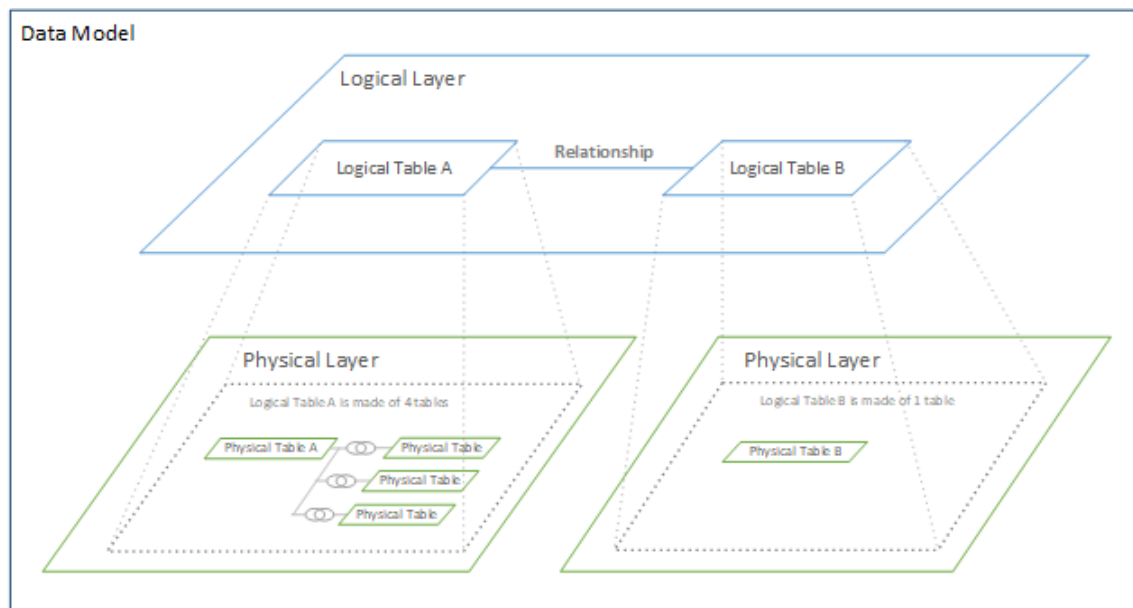

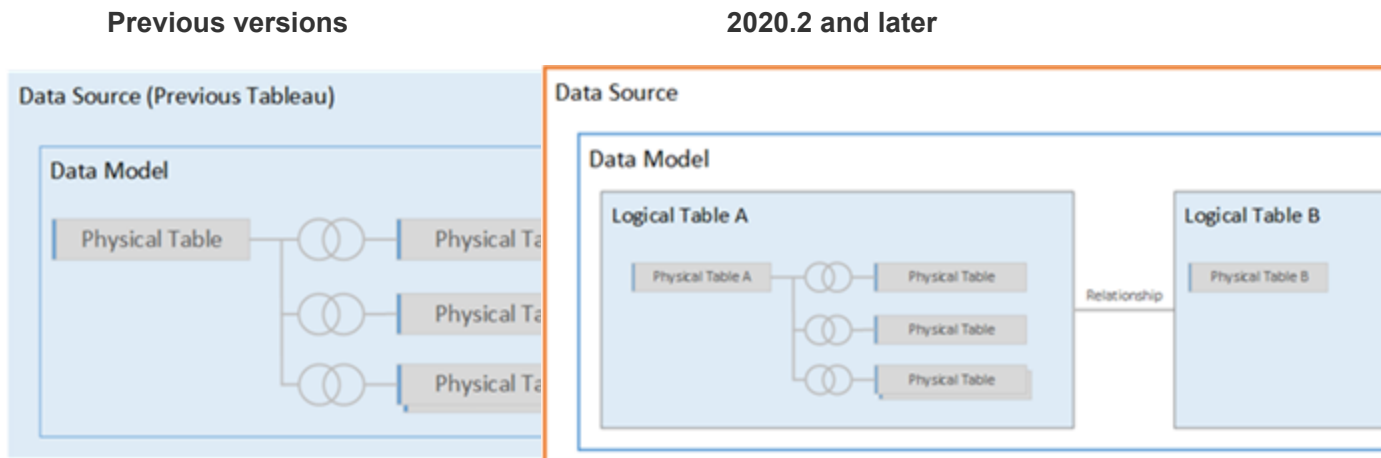

Tableau Server on Windows Help

In Tableau 2020.2 and later, a logical layer has been added in the data source. Each logical table contains physical tables in a physical layer.

In previous versions of Tableau, the data model in your data source consisted of a single, physical layer where you could specify joins and unions. Tables added to the physical layer (joined or unioned) create a single, flattened table (denormalized) for analysis.

In versions of Tableau before 2020.2, the data model has only the physical layer

In 2020.2 and later, the data model has two layers: the logical layer and the physical layer

As of Tableau 2020.2, the data model in your data source includes a new semantic layer above the physical layer—called the logical layer—where you can add multiple tables and relate them to each other. Tables at the logical layer are not merged in the data source, they remain distinct (normalized), and maintain their native level of detail.

Logical tables act like containers for merged physical tables. A logical table can contain a single, physical table. Or it can contain multiple physical tables merged together through joins or unions.

Build a new model

When you add one or more tables to the logical layer, you are essentially building the data model for your data source. A data source can be made of a single, logical table, or you can

drag multiple tables to the canvas to create a more complex model.

- The first table that you drag to the canvas becomes the root table for the data model in your data source.
- After you drag out the root table, you can drag out additional tables in any order. You will need to consider which tables should be related to each other, and the matching field pairs that you define for each relationship.
- If you are creating a star schema, it can be helpful to drag the fact table out first, and then relate dimension tables to that table.
- Deleting a table in the canvas automatically deletes its related descendants as well. If you delete the root table, all other tables in the model are also removed.
- Each relationship must be made of at least one matched pair of fields. Add multiple field pairs to create a compound relationship. Matched pairs must have the same data type. Changing the data type in the Data Source page does not change this requirement. Tableau will still use the data type in the underlying database for queries.
- Relationships can be based on calculated fields.
- You can specify how fields used in the relationships should be compared by using operators when you define the relationship.

For more information about relationships, see [Create and define relationships](#) in [Relate Your Data](#).

Multi-table model

- To create a multi-table model, drag tables to the logical layer of the Data Source page canvas.

Tables that you drag to the logical layer of the Data Source page canvas must be related to each other. When you drag additional tables to the logical layer canvas, Tableau automatically attempts to create the relationship based on existing key constraints and matching fields to define the relationship. If it can't determine the matching fields, you will need to select them.

If no constraints are detected, a **Many-to-many** relationship is created and referential integrity is set to **Some records match**. These default settings are a safe choice and provide the most a lot of flexibility for your data source. The default settings support full outer joins and optimize queries by aggregating table data before forming joins during analysis. All column and row data from each table becomes available for analysis.

You can add more data inside any logical table by double-clicking the table. This opens the physical layer of the Data Source page canvas. If you need to use joins or unions, you can drag the tables you want to join or union into the physical layer canvas. The physical tables are merged in their logical table.

Follow the steps in [Create and define relationships](#) to combine multiple tables.

Single-table model

- To create a single-table model, drag a table into the logical layer canvas of the Data Source page. You can then use the fields from that table in the Data pane for analysis.

Single-table model that contains other tables

You can add more data inside the single, logical table by double-clicking the table. This opens the physical layer of the Data Source page canvas. If you need to use joins or unions, you can drag the tables you want to join or union into the physical layer canvas. The physical tables are merged in their logical table.

This example shows the Book table in the Relationships canvas (logical layer) of the data source. Double-clicking the Book logical table opens the Join/Union canvas (physical layer).

In this example, the joins merge the Award and Info tables with the Book table. In this case, the join between Book and Award will be one-to-many, at the level of detail of awards. This would duplicate measure values for Book and Info. To avoid duplication, you could relate Award and Info to Book instead of joining them inside of the Book logical table.

Supported data model schemas

The data modeling capabilities introduced to Tableau in 2020.2 are designed to make analysis over common multi-table data scenarios—including star and snowflake data models—easy. The following types of models are supported in Tableau data sources.

Single-table

Analysis over a single logical table that contains a mixture of dimensions and measures works just as in Tableau pre-2020.2. You can build a logical table using a combination of joins,

unions, custom SQL, and so on.

Star and snowflake

In enterprise data warehouses, it is common to have data structured in star or snowflake schemas where measures are contained in a central fact table and dimensions are stored separately in independent dimension tables. This organization of data supports many common analysis flows including rollup and drill down.

These models can be directly represented with relationships in the data modeling capabilities available starting with Tableau 2020.2.

Drag the fact table into the model first and then relate the dimension tables to the fact table (in a star schema) or to other dimension tables (in a snowflake).

Typically, in a well-modeled star or snowflake schema, the relationships between the fact table and the dimension tables will be many-to-one. If this information is encoded in your data warehouse, Tableau will automatically use this to set the relationship's Performance Options. If not, you can set this information yourself. For more information, see [Optimize Relationship Queries Using Performance Options](#).

In a well-modeled star or snowflake schema, every row in the fact table will have a matching entry in each of the dimension tables. If this is true and captured in your data warehouse integrity constraints, Tableau will automatically use this information to set the referential integrity setting in Performance Options. If some fact table rows do not have a matching row in a dimension table (sometimes called "late-arriving dimensions" or "early-arriving facts"), Tableau will default to retaining all rows when computing measures, but may drop values when showing dimension headers. For more information, see [Optimize Relationship Queries Using Performance Options](#).

Star and snowflake with measures in more than one table

In some star or snowflake schemas, all the measures for your analysis are contained in the fact table. However, it is often true that additional measures of interest may be related to the dimension tables in your analysis. Even if the dimension tables do not contain measures, it is common in analysis to want to count or otherwise aggregate dimension values. In these cases, the distinction between fact tables and dimension tables is less clear. To create clarity when viewing your data model, we recommended adding the finest grain table to the data source canvas first, and then relating all other tables to that first table.

If you were to join these tables together into a single logical table, the measures in the dimension tables would be replicated, resulting in distorted aggregates unless you took precautions to deduplicate the values using LOD calculations or `COUNT DISTINCT`. However, if you instead create relationships between these tables, Tableau will aggregate measures before performing joins, avoiding the problem of unnecessary duplication. This relieves you of the need to carefully track the level of detail of your measures.

Multi-fact analysis

Tableau's data modeling capabilities support some forms of multi-fact analysis. Additional fact tables (containing measures) can be added to any of the previously mentioned models as long as they only relate to a single dimension table. For example, you can bring two or more fact tables together to analyze a shared dimension, such as in Customer 360-like analyses. These fact tables can be at a different level of detail than the dimension table, or from each other. They can also have a many-to-many relationship with the dimension table. In these scenarios, Tableau will ensure that values are not replicated before aggregation.

If you don't have a shared dimension table that relates your fact tables, you can sometimes dynamically build one using custom SQL or by using joins or unions of other dimension tables.

Two fact tables can be related directly to each other on a common dimension. This type of analysis works best when one of the fact tables contains a superset of the common dimension.

Unsupported models

- **Multiple fact tables related to multiple shared dimension tables.** In some use cases it is common to have multiple fact tables related to multiple shared dimension tables. For example, you might have two fact tables, Store Sales and Internet Sales, related to two common dimension tables, Date and Customer. Typically, such scenarios would require creating a circular relationship in your data model. Circular relationships are not currently supported.

You can approximate this type of model by merging some of the tables in the physical layer. For example, you might be able to union Store Sales and Internet Sales into a single table, which can then be related to Date and Customer. Alternatively, you might be able to cross-join Date and Customer to create a single dimension table which can then be related to Store Sales and Internet Sales.

- **Directly relating 3 or more fact tables on shared dimensions.** While it is possible to build this model in the logical layer, you might see unwanted results, unless you only use dimensions from a single table.

Requirements for relationships in a data model

- When relating tables, the fields that define the relationships must have the same data type. Changing the data type in the Data Source page does not change this requirement. Tableau will still use the data type in the underlying database for queries.
- You can't define relationships based on geographic fields.
- Circular relationships aren't supported in the data model.
- You can't define relationships between published data sources.

Factors that limit the benefits of using related tables

- Dirty data in tables (i.e. tables that weren't created with a well-structured model in mind and contain a mix of measures and dimensions in multiple tables) can make multi-table analysis more complex.
- Using data source filters will limit Tableau's ability to do join culling in the data. Join culling is a term for how Tableau simplifies queries by removing unnecessary joins.
- Tables with a lot of unmatched values across relationships.
- Interrelating multiple fact tables with multiple dimension tables (attempting to model shared or conformed dimensions).

How Relationships Differ from Joins

Relationships are a dynamic, flexible way to combine data from multiple tables for analysis. You don't define join types for relationships, so you won't see a Venn diagram when you create them.

Think of a relationship as a contract between two tables. When you are building a viz with fields from these tables, Tableau brings in data from these tables using that contract to build a query with the appropriate joins.

- **No up-front join type.** You only need to select matching fields to define a relationship ([no join types](#)). Tableau first attempts to create the relationship based on existing key constraints and matching field names. You can then check to ensure they are the fields you want to use, or add more field pairs to better define how the tables should be related.
- **Automatic and context-aware.** Relationships defer joins to the time and context of analysis. Tableau automatically selects join types based on the fields being used in the visualization. During analysis, Tableau adjusts join types intelligently and preserves the native level of detail in your data. You can see aggregations at the level of detail of the fields in your viz rather than having to think about the underlying joins. You don't need to use LOD expressions such as FIXED to deduplicate data in related tables.
- **Flexible.** Relationships can be many-to-many and support full outer joins. When you combine tables using relationships, it's like creating a custom, flexible data source for every viz, all in a single data source for the workbook. Because Tableau queries only tables that are needed based on fields and filters in a viz, you can build a data source that can be used for a variety of analytic flows.

For more information, see [Relate Your Data](#) and [Don't Be Scared of Relationships](#).

Joins are still available as an option for combining your data. Double-click a logical table to go to the join canvas. For more information, see [Where did joins go?](#)

Watch a video: For an introduction to using relationships in Tableau, see this 5-minute video.

Note: The interface for editing relationships shown in this video might differ slightly from the current release but has the same functionality.

Also see video podcasts on relationships from [Action Analytics](#), such as [Why did Tableau Invent Relationships?](#) Click "Video Podcast" in the [Library](#) to see more.

For related information about how relationship queries work, see these Tableau blog posts:

- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)
- [Relationships, part 3: Asking questions across multiple related tables](#)

Characteristics of relationships and joins

Relationships are a dynamic, flexible way to combine data from multiple tables for analysis. We recommend using relationships as your first approach to combining your data because it makes data preparation and analysis easier and more intuitive. [Use joins only when you absolutely need to.](#)

Here are some advantages to using relationships to combine tables:

- Make your data source easier to define, change, and reuse.
- Make it easier to analyze data across multiple tables at the correct level of detail (LOD).
- Do not require the use of LOD expressions or LOD calculations for analysis at different levels of detail.
- Only query data from tables with fields used in the current viz.

Relationships

- Are displayed as flexible noodles between logical tables
- Require you to select matching fields between two logical tables
- Do not require you to select join types
- Make all row and column data from related tables potentially available in the data source
- Maintain each table's level of detail in the data source and during analysis
- Create independent domains at multiple levels of detail. Tables aren't merged together in the data source.
- During analysis, create the appropriate joins automatically, based on the fields in use.

- Do not duplicate aggregate values (when Performance Options are set to Many-to-Many)
- Keep unmatched measure values (when Performance Options are set to Some Records Match)

Joins

Joins are a more static way to combine data. Joins must be defined between physical tables up front, before analysis, and can't be changed without impacting all sheets using that data source. Joined tables are always merged into a single table. As a result, sometimes joined data is missing unmatched values, or duplicates aggregated values.

- Are displayed with Venn diagram icons between physical tables
- Require you to select join types and join clauses
- Joined physical tables are merged into a single logical table with a fixed combination of data
- May drop unmatched measure values
- May duplicate aggregate values when fields are at different levels of detail
- Support scenarios that require a single table of data, such as extract filters and aggregation

Requirements for using relationships

- When relating tables, the fields that define the relationships must have the same data type. Changing the data type in the Data Source page does not change this requirement. Tableau will still use the data type in the underlying database for queries.
- You can't define relationships based on geographic fields.
- Circular relationships aren't supported in the data model.
- You can't define relationships between published data sources.

Factors that limit the benefits of using related tables

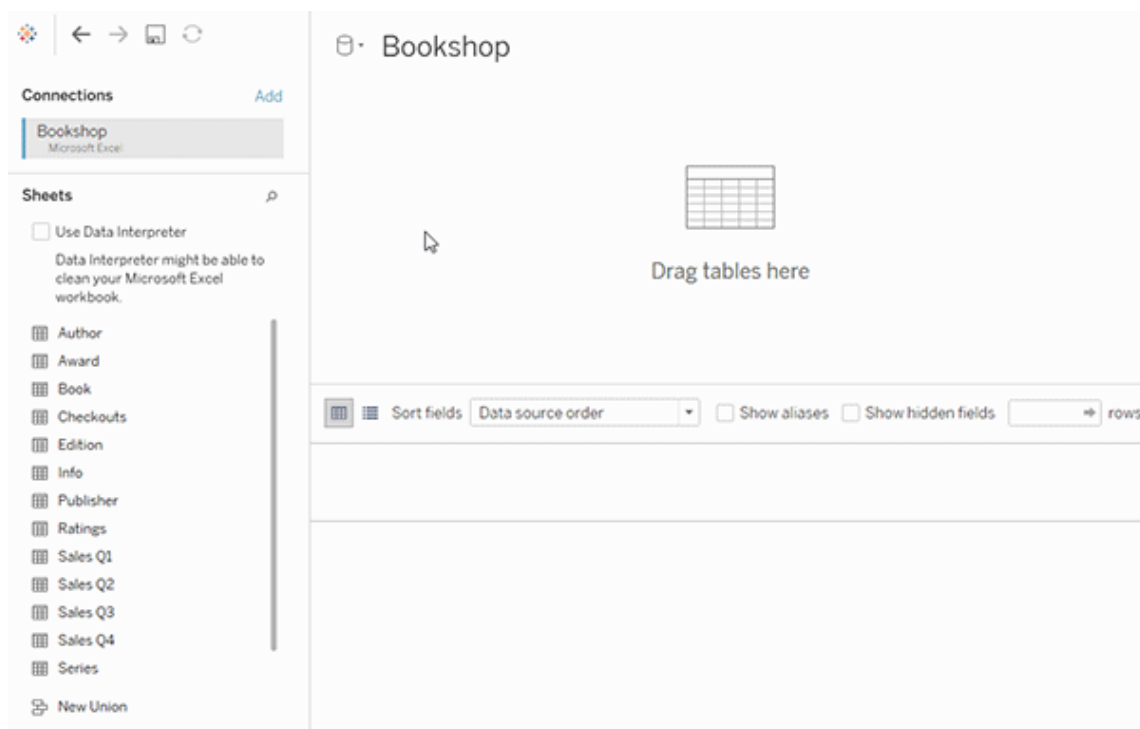

- Dirty data in tables (i.e. tables that weren't created with a well-structured model in mind and contain a mix of measures and dimensions in multiple tables) can make multi-table analysis more complex.
- Using data source filters will limit Tableau's ability to do join culling in the data. Join culling is a term for how Tableau simplifies queries by removing unnecessary joins.
- Tables with a lot of unmatched values across relationships.

- Interrelating multiple fact tables with multiple dimension tables (attempting to model shared or conformed dimensions).

Where did joins go?

You can still specify joins between tables in the physical layer of a data source. Double-click a logical table to go to the Join/Union canvas in the physical layer and add joins or unions.

Every top-level, logical table contains at least one physical table. Open a logical table to view, edit, or create joins between its physical tables. Right-click a logical table, and then click **Open**. Or, just double-click the table to open it.

When you create a data source, it has two layers. The top-level layer is the logical layer of the data source. You combine data between tables in the logical layer using relationships.

The next layer is the physical layer of the data source. You combine data between tables at the physical layer using joins. For more information, see [Logical and physical tables in the data model](#).

Optimize Relationship Queries Using Performance Options

Performance Options are optional settings that define the cardinality (uniqueness) and referential integrity (matching records) between the two tables in a relationship. These settings help Tableau optimize queries during analysis.

- **If you aren't sure what to choose**, use the recommended default settings indicated by Tableau. Using the defaults is safe and will automatically generate correct aggregations and joins during analysis. If you don't know the cardinality or referential integrity, you don't need to change these settings.
- **If you know the shape of your data**, you can optionally change these settings to represent uniqueness and matching between the records in the two tables.

In many analytical scenarios, using the default settings for a relationship will give you all of the data you need for analysis. In some scenarios, you might want to adjust the Performance Options settings to describe your data more accurately. For more details about using relationships to combine and analyze data, see [Relate Your Data](#) and this Tableau blog post: [Relationships, part 1: Introducing new data modeling in Tableau](#).

What the Cardinality and Referential Integrity settings mean

Edit Relationship [X]

Orders	States
Abc State	Abc State Name
+ Add more fields	

^ Performance Options

Cardinality	Referential Integrity
Many ▼	Many ▼
Some records match ▼	Some records match ▼

[Revert to Default](#)

Cardinality options

Cardinality settings determine if Tableau aggregates table data before or after automatically joining the data during analysis.

- Select **Many** if the field values aren't unique, or you don't know. Tableau will aggregate the relevant data before forming joins during analysis.
- Select **One** if field values are unique. During analysis, the relevant data will be joined before aggregation. Setting this option correctly optimizes queries in the workbook when the field values in the relationship are unique. However, selecting **One** when field values aren't unique can result in duplicate aggregate values being shown in the view.

Note: Selecting **One** treats records as if each key value is unique and there is at most only one row with a null value.

Referential Integrity options

Referential Integrity settings determine the type of join used to get the dimension values for a measure during analysis.

- Select **Some Records Match** if some values in the field don't have a match in the other table, or you don't know. During analysis, Tableau uses outer joins to get dimensions values for a measure. All measure values will be shown in the view, even unmatched measures.
- Select **All Records Match** if values in the field are guaranteed to have a match in the other table. This setting generates fewer and simpler joins during analysis, and optimizes queries. You might see inconsistent results during analysis (unmatched values removed or missing in view) if there are unmatched values in this table.

Notes: Selecting **All Records Match** treats records as if no null values exist in the fields used for the relationship. During analysis, Tableau will use inner joins to get dimension values for a measure. By default, Tableau will never join null keys.

For more information about Cardinality and Referential integrity as concepts, see [Cardinality and Referential Integrity](#).

Where did joins go?

You can still specify joins between tables in the physical layer of a data source. Double-click a logical table to go to the join canvas.

Every top-level, logical table contains at least one physical table. Open a logical table to view, edit, or create joins between its physical tables. Right-click a logical table, and then click **Open**. Or, just double-click the table to open it.

When you create a data source, it has two layers. The top-level layer is the logical layer of the data source. You combine data between tables in the logical layer using relationships.

The next layer is the physical layer of the data source. You combine data between tables at the physical layer using joins. For more information, see [Logical and physical tables in the data model](#).

Tips on using Performance Options

If you know the shape of your data, you can use the optional settings in Performance Options to establish the cardinality of the tables to each other (one-to-one, one-to-many, many-to-many) and indicate referential integrity (values from one table will always have match in the other table).

Instead of thinking of the settings in Performance Options as “yes” and “no”, think of them as “yes” and “I don’t know”. If you are sure that a table's values are unique, select **One**. If you are sure that each record in one table matches one or more records in the other table, select **All Records Match**. Otherwise, leave the default settings as they are.

If you aren't sure about the shape of your data, use the default settings. When Tableau can't detect these settings in your data, the default settings are:

- Cardinality: Many-to-Many
- Referential integrity: Some Records Match

If Tableau detects key relationships or referential integrity in your data, those settings will be used and indicated as "detected".

To reapply the default settings, click **Revert to Default**.

Terms defined

Cardinality refers to the uniqueness of data contained in a field (column) or combination of fields. When the tables you want to analyze contain many rows of data, queries can be slow (and performance of the overall data source is affected) so we recommend choosing a method for combining data based on the cardinality of the related columns between tables.

- Low cardinality: When related columns have a lot of repeated data. For example, a table called Products might contain a Category column that contains three values: Furniture, Office Supplies, and Technology.
- High cardinality: When related columns have highly unique data. For example, a table called Orders might contain an Order ID column that contains a unique value for every order of product.

Referential integrity means that one table will always have a matching row in the other table. For example, a Sales table will always have a matching row in the Product Catalog table.

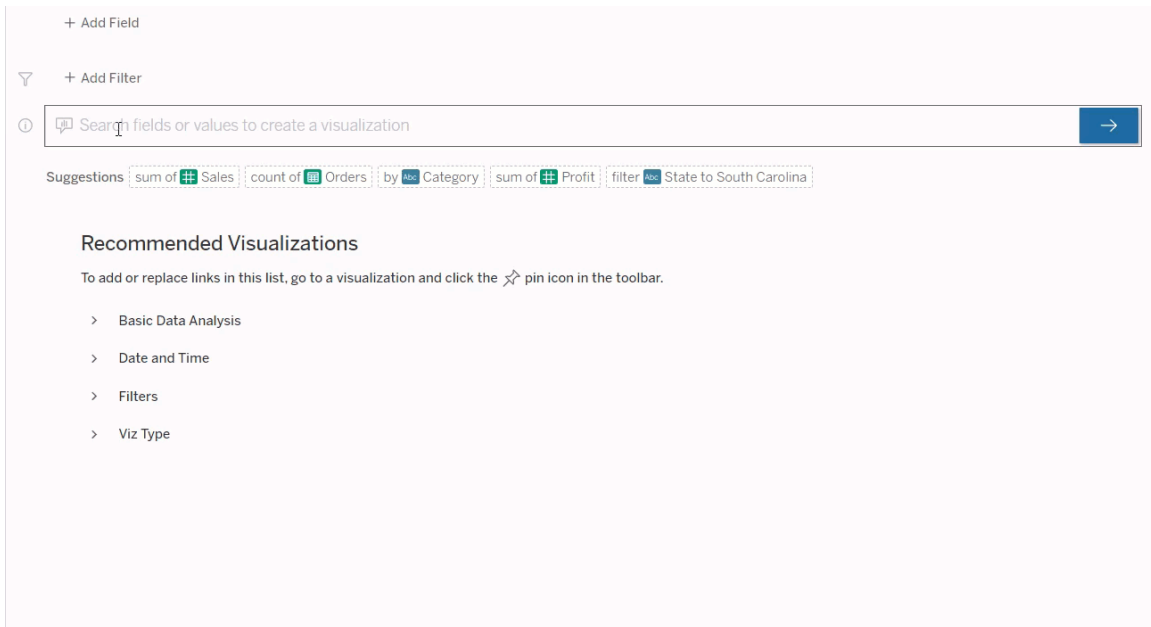

Automatically Build Views with Ask Data

Important changes coming for Ask Data and Metrics

Tableau's Ask Data and Metrics features will be retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau GPT and Tableau Pulse are reimagining the data experience](#).

Ask Data lets you type a question in common language and instantly get a response right in Tableau. Answers come in the form of automatic data visualizations, with no need to manually drag-and-drop fields or understand the nuances of your data's structure.

Ask Data lets you ask sophisticated questions naturally, with support for key analytical concepts such as time series and spatial analysis, and an understanding of conversational phrases such as "last year" and "most popular."

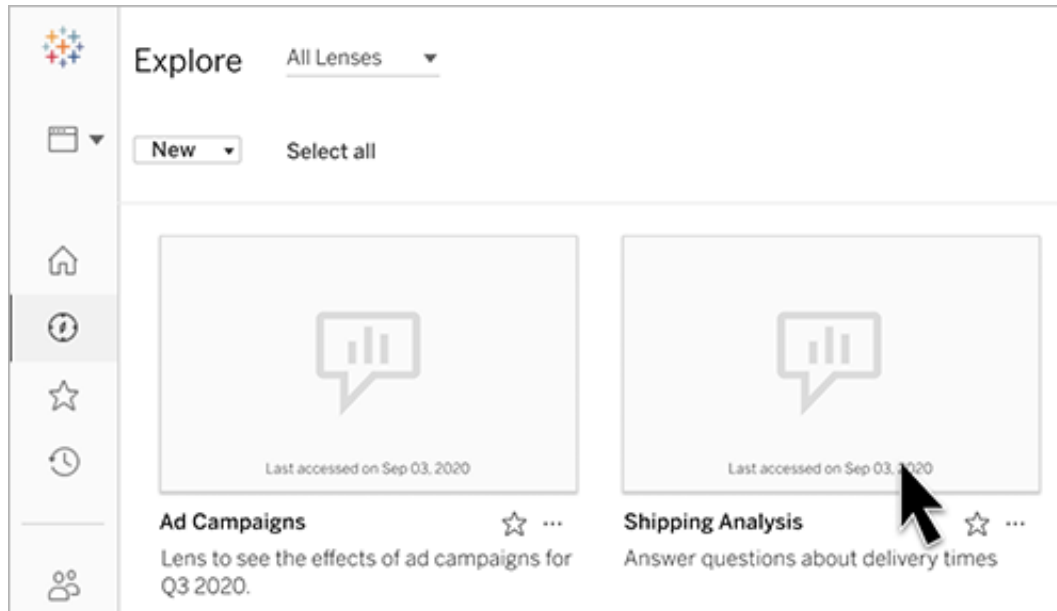

Navigating to Ask Data lenses

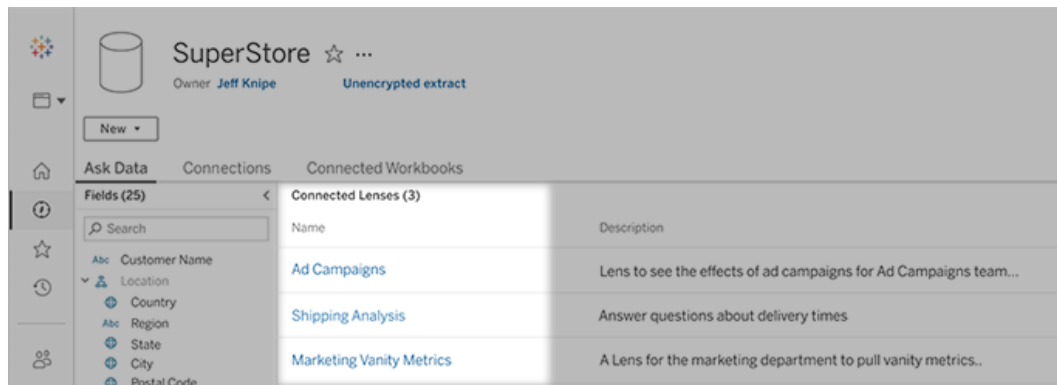

Before you can query a data source with Ask Data, **a Tableau author must first create a lens** that specifies the subset of data fields the lens uses.

In Tableau, here are all the places where you can access an Ask Data lens:

- On the All Lenses page at the top level of your Tableau Cloud or Tableau Server site.

- On the Ask Data tab for a data source for which lenses have been created.

- In an Ask Data object on a dashboard.

Ask Data from a lens page or dashboard object

Navigate to a lens and learn more about its data

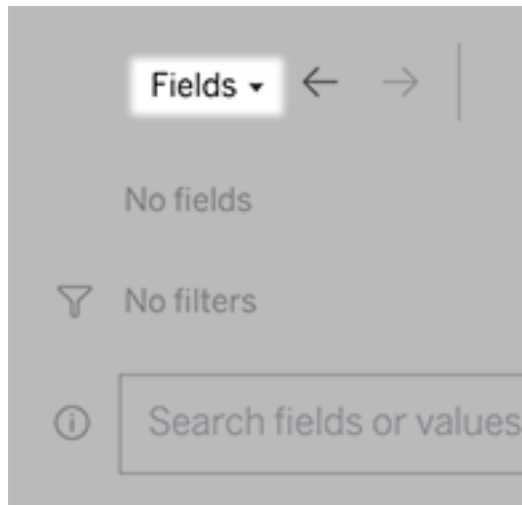

1. Navigate to a lens via the All Lenses page for your Tableau site, the Ask Data tab for a data source, or an Ask Data object on a dashboard.
2. (Optional) Under **Recommended Visualizations**, click an entry to quickly see visualizations the lens author has created for your organization.

If the recommendations don't address your current data analysis needs, [build a query](#) to create your own question.

3. In the Data pane at left, briefly hover over each field to learn more about the data it contains.

In a narrower dashboard object, the Data pane may be hidden, but you can see the same information by clicking the **Fields** drop-down menu.

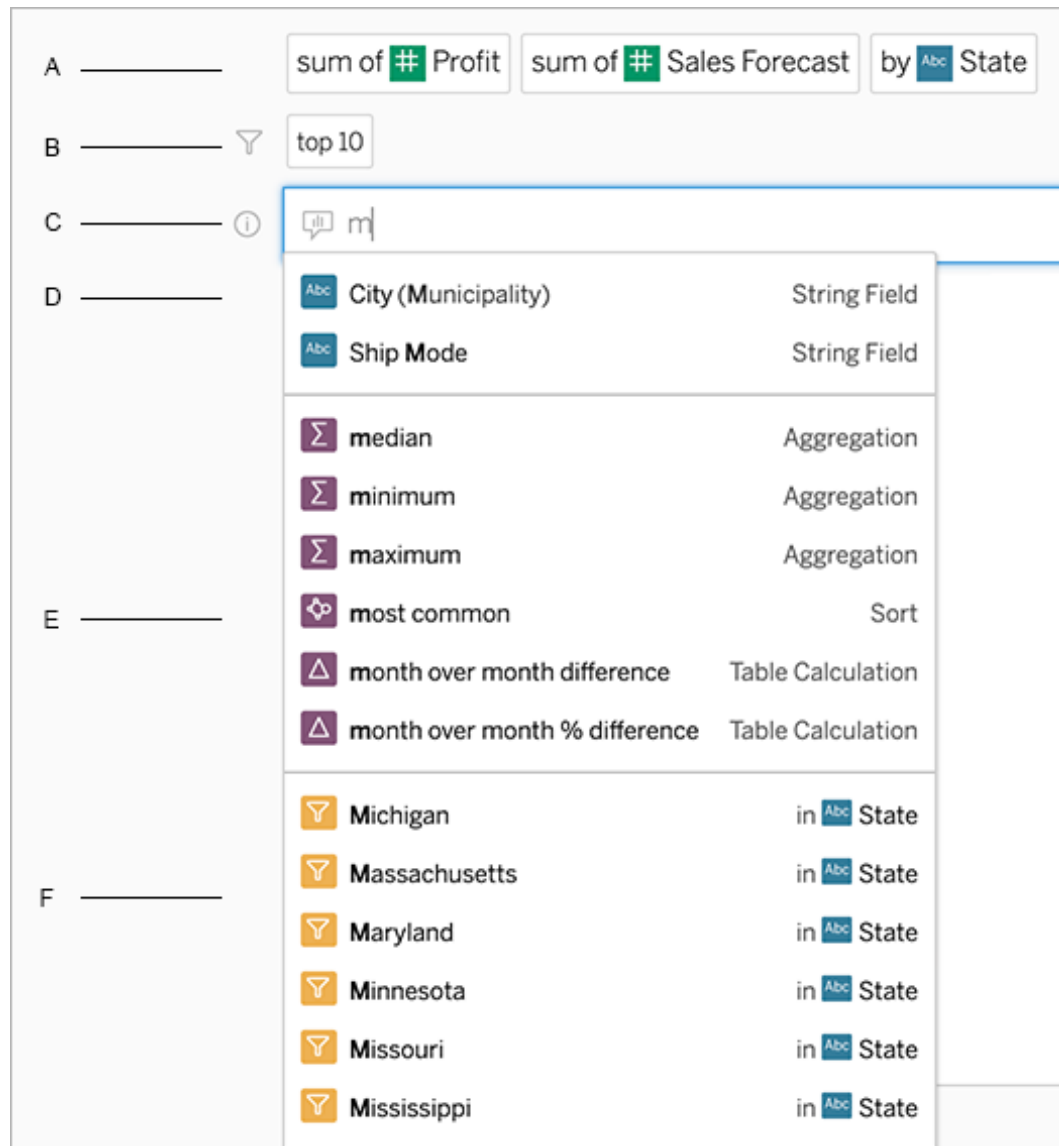

Build queries by entering text

1. Type in the box reading **Search fields or values to create a visualization.**

2. As you type, Ask Data searches data fields, functions, and string values and displays results in a drop-down list. Click items in the list to add them to your current entry, shown above the search box. To automatically create a viz using the current entry, press **Enter** at any time.

Modifying a query by searching for fields and analytical functions

A. Current entry B. Current filters C. Search box D. Returned fields E. Returned analytical functions F. Returned field values

Build queries by adding suggested phrases

Tableau will suggest phrases based on the most common queries asked in your lens and by others in your organization. When you open your lens, you'll notice suggestions that will help

Tableau Server on Windows Help

you get quick answers to common questions.

You can add these suggestions to your query by clicking them. As you add phrases to your query, the suggestions dynamically update with more relevant phrases. The view automatically builds with each selection.

Build queries by adding fields and filters

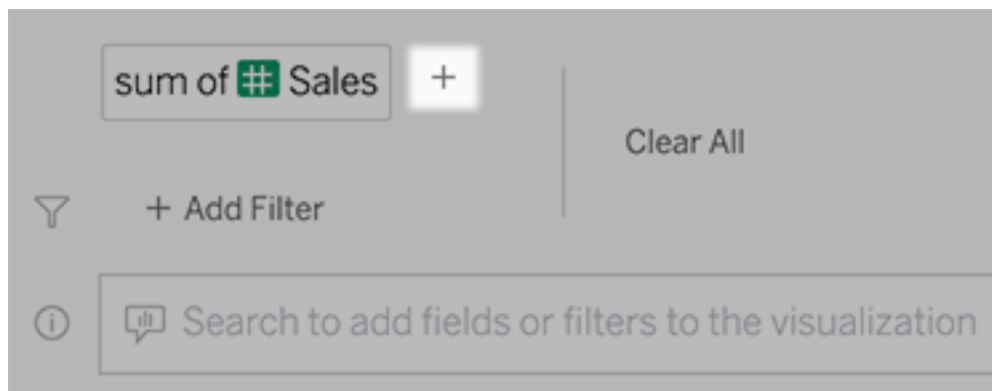

1. Click **Add Field** or **Add Filter**.

2. Click the desired field. (To narrow down a long list, first type in the **Search Fields** box.)

3. Set any sub-options, such as aggregation type for a numeric field, or grouping for string and date fields.
4. To add more fields or filters, click the plus sign.

See how elements of your query are applied

To see how elements of your query are applied, hover over them in the text box or the interpretation above it. Words that aren't used are grayed out, helping you rephrase your query in a way that's clearer to Ask Data.

Rephrase your question

You can rephrase questions by clicking options, data fields, and filters in the user interface.

Change the viz type

If the default viz doesn't fully reveal your data, click the menu at upper right, and choose from these supported viz types:

- Bar Chart
- Gantt Bar
- Heat Map
- Histogram
- Line Chart
- Map
- Pie Chart
- Scatter
- Stacked Bar Chart
- Text Table
- Treemap

Note: To automatically create certain viz types, Ask Data sometimes adds fields such as "Number of Records" to your entries.

Change fields, filters, and displayed data

Ask Data gives you several ways to fine-tune how field values are displayed.

- To switch the fields used for the vertical and horizontal axes, click the Swap Axes button  to the left of the viz selection menu:

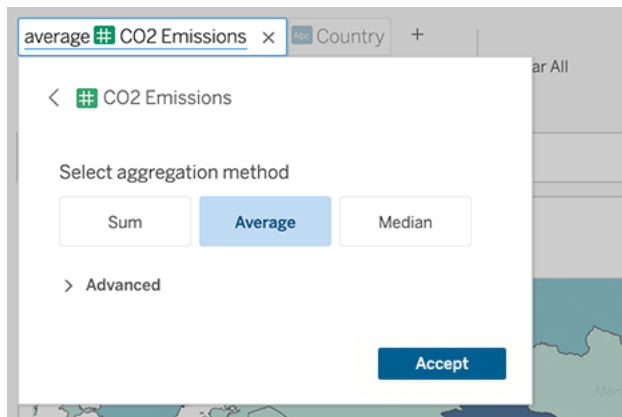

- To change a field, first click it in your query entry, and then click the field name below.
(To change fields used in difference calculations, see Compare differences over time.)

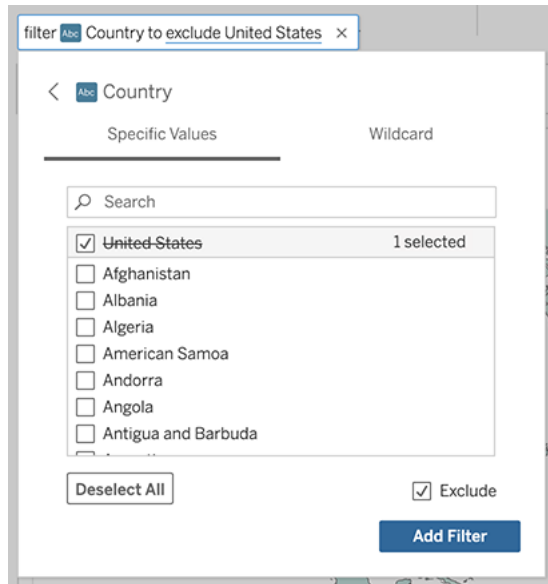

Tableau Server on Windows Help

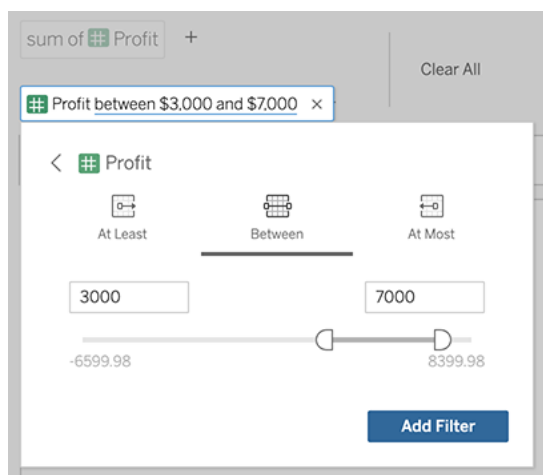

- To change a field's aggregation or grouping type (for example, from average to sum), click the field name in the text box, and then choose a different aggregation or grouping.

- For categorical filters, click values (for example, "exclude United States" in the example below) to change specific values or enter wildcard parameters.

- To adjust a numeric range, click words such as "high" or "cheap."

- To delete a field or filter, hover over it and click the **X**.

Adjust date filters

To adjust a date filter, click words such as "last" or "previous." Then click one of the following:

- **Specific Dates** to enter a specific time period or date value
- **Relative Dates** to show a date range relative to the present day
- **Range of Dates** to enter specific start and end points

Specific Dates offers some unique options in the **Date Detail** menu:

- **Time Period** options show a single continuous date range
- **Date Value** options show ranges that can repeat in multiple time periods. For example, to see combined sales performance for Q1 across multiple years, under Date Value, you would choose Quarters.

Compare differences over time

Ask Data lets you compare time periods with phrases such as "year over year" or "quarter over quarter." The results appear as difference or percent difference table calculations in workbooks you save from Ask Data.

In the text box, click a difference calculation to choose other fields, aggregation methods, and time periods.

Apply simple calculations

Ask Data supports simple calculations between two measures, which you can apply using these symbols:

- + sums the measures
- produces the difference between them
- * multiplies
- / divides

In workbooks you save from Ask Data, these calculations don't become calculated fields but instead ad hoc calculations on the Columns, Rows, or Marks shelves.

Add sheets with other vizzes

To quickly create multiple different vizzes from a lens, add sheets in Ask Data.

At the bottom of the web page, do any of the following:

- Click the **Add Sheet** icon to the right of named sheets.

- Right-click a sheet name, and choose either **Duplicate** or **Delete**.

(To rename sheets from Ask Data, you need to save them in a new workbook.)

Share Ask Data vizzes via email, Slack, or a link

You can quickly share Ask Data vizzes with anyone who has access to a lens.

1. In the upper right corner of the browser, click the Share icon.

2. Do either of the following:
 - To share the viz via email or Slack, enter specific user names in the text box. (Email and Slack integration must previously be configured by your Tableau administrator.)
 - To copy a URL you can paste into custom emails and other messages, click **Copy Link**.

Send feedback to the lens owner

If you have questions about the structure of a lens or how best to use it with Ask Data, you can send feedback directly to the author. (This option is enabled by default, but lens authors may disable it.)

1. To the left of the query box for Ask Data, click the **Ask Data tips** icon.

2. At the bottom of the tips dialog, click **Contact the Lens Author**.

Tips for successful queries

As you structure questions for Ask Data, apply these tips to get better results.

- **Use keywords** — For example, instead of "I want to see all the countries that these airports are in, try "by airport and country."
- **Use exact wording for field names and values** — For example, if your lens includes Airport Code, Airport Name, and Airport Region fields, specify those by name.
- **See a ranked list** — Ask Data maps terms such as "best" and "worst" to Top 1 and Bottom 1, respectively. If you want to see broader rankings, use "high" and "low" instead. For example, enter "houses with low sale prices."
- **Query table calculations** — In query expressions for table calculation fields, note that you can't filter, limit, or include "year over year difference."
- **Surround unusually long values with quotation marks** — To analyze long field values that contain line returns, tabs, or more than ten words, surround them with quotation marks. To improve performance, Ask Data doesn't index fields of that length, or anything beyond the first 200,000 unique field values.

Create Lenses that Focus Ask Data for Specific Audiences

Important changes coming for Ask Data and Metrics

Tableau's Ask Data and Metrics features will be retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau GPT and Tableau Pulse are reimagining the data experience](#).

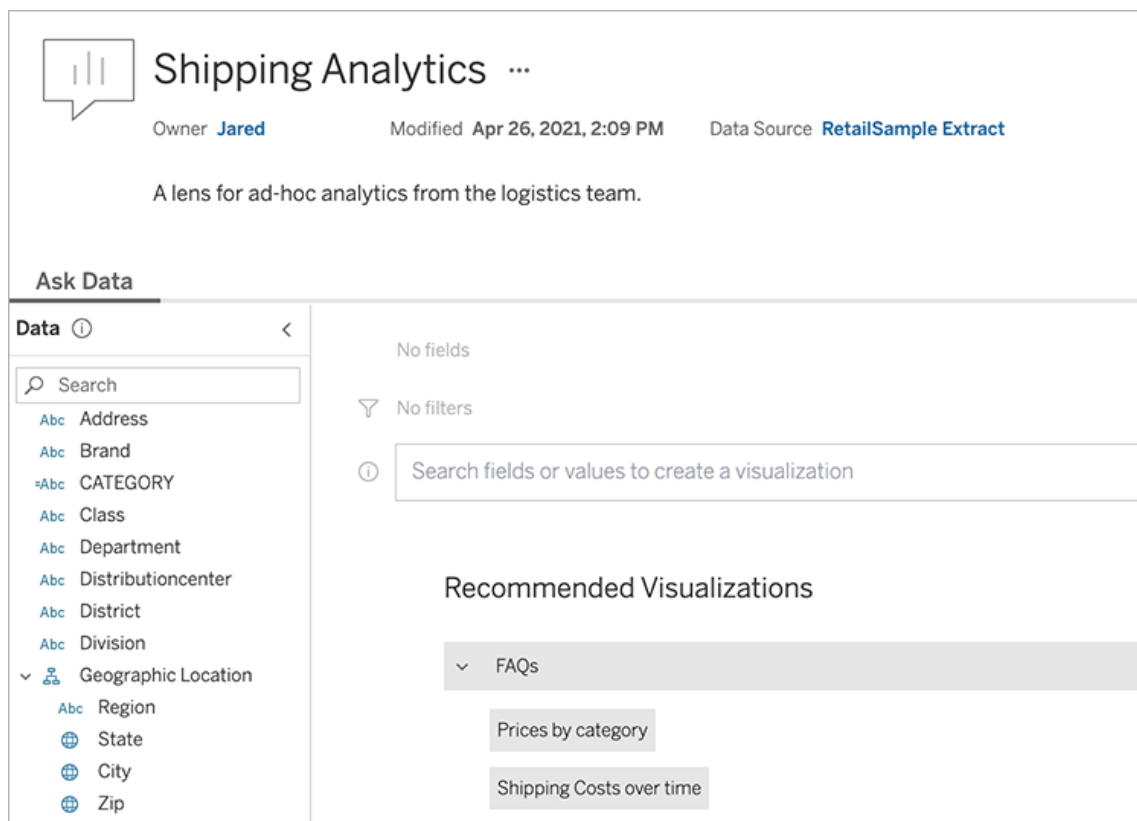

Most people don't need information from an entire data source but instead want data visualizations relevant to their job function, like sales, marketing, or support. To optimize Ask Data for different audiences like these, Tableau authors create separate Ask Data *lenses*, which query a selected subset of fields. For the selected fields, authors can specify synonyms for field names and values, reflecting terms the lens audience uses in common language (for example, "SF" for "San Francisco"). Lens authors then customize the recommended visu-

alizations that appear below the Ask Data query box, which provide answers to users with a single click.

Note: Ask Data lenses can be created only for data sources published separately to a Tableau site. Lenses can't be created for data sources embedded in workbooks or those with a virtual connection.

Create or configure a lens page on your Tableau site

On your Tableau site, each lens has a separate page where users can query Ask Data and authors can configure lens fields, synonyms, and suggested questions.

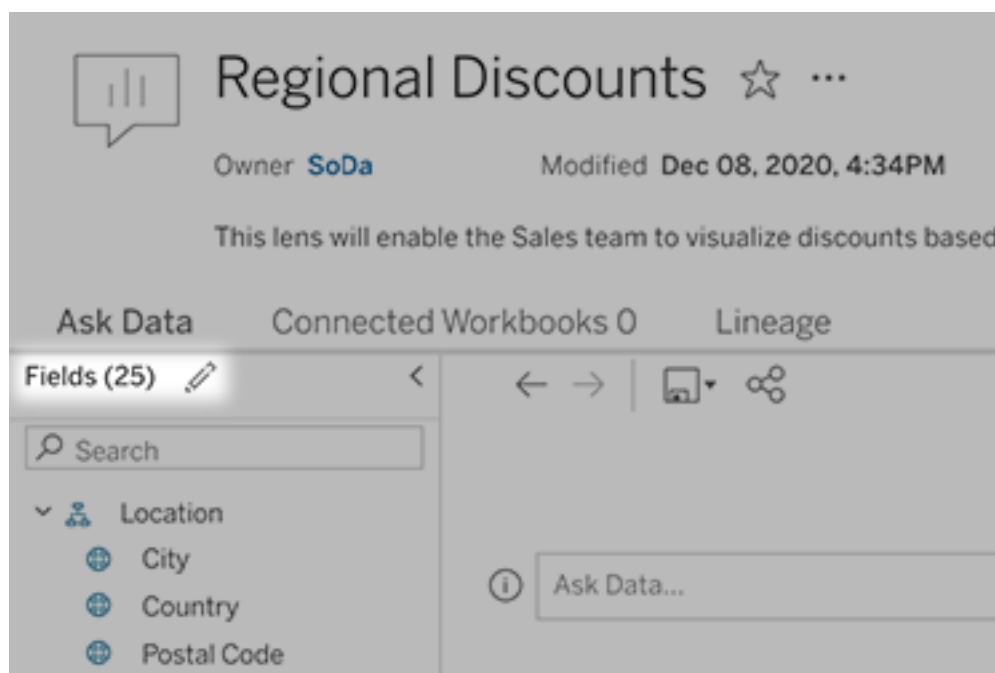

A lens page on a Tableau site

1. To create a lens page on your Tableau site, go to a data source page, and choose **New > Ask Data Lens**.

To configure an existing lens, go to the lens page on your site. (From an Ask Data object in a dashboard, you can click the pop-up menu in the upper corner and choose **Go to Lens Page**.)

2. If you're creating a new lens, enter a name, description, and project location, and then click **Publish Lens**.
3. At the top of the Fields pane at left, click the pencil icon. Then select the relevant fields for lens users, and click **Save**.

4. At left, hover over individual tables or fields, and click the pencil icon:

Then do any of the following:

- Provide a more representative name by clicking the pencil icon to the right.

- Add common synonyms for field names and values that lens users may enter in their queries.
- Edit descriptions that appear when users hover over fields.

Change the list of recommended visualizations

To address common queries from lens users, you can customize the recommended visualizations that appear below the query box.

Add or replace a recommended visualization

1. Enter a query into the text box, and press Enter or Return.
2. After the visualization appears, from the pin icon in the toolbar, choose either **Pin to Recommended Visualizations** or **Replace Recommendation**.

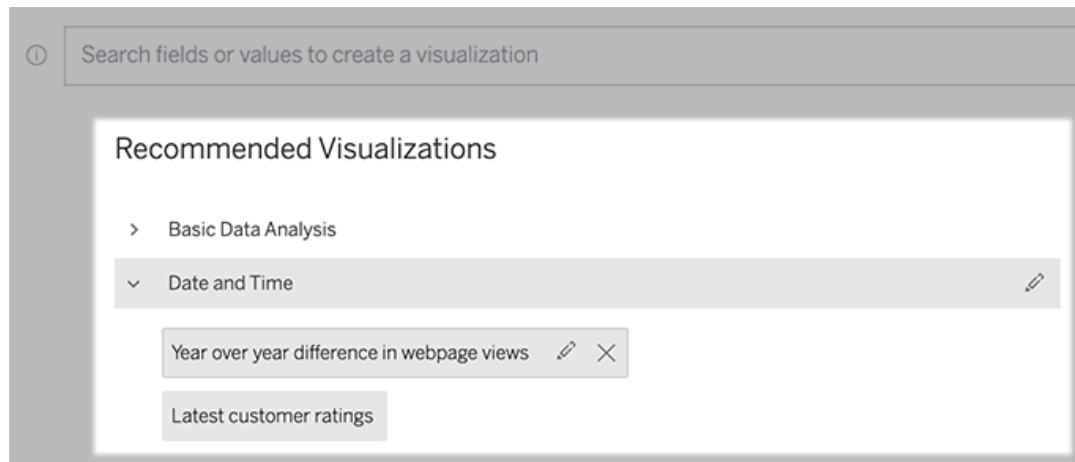

Tableau Server on Windows Help

3. For a new recommendation, enter a name, and choose the section in which you want it to appear. For a replacement recommendation, choose the existing one you want to overwrite.

Edit section titles and recommendation names, or delete recommendations

- To edit a section title, click the pencil icon  to the right of the title.
 - To change the name of a recommendation, hover over it and click the pencil icon .
- To delete a recommendation, click the X.

Add an Ask Data lens to a dashboard

On a dashboard, you can add an Ask Data object that lets users query a published data source via a lens on your Tableau site.

1. While editing a dashboard in Tableau Cloud or Tableau Server, drag the Ask Data object to the canvas.

Note: In Tableau Desktop, you can also drag an Ask Data object to the canvas for placement purposes. But to select a lens, you will need publish to Tableau Cloud or Tableau Server and edit the object there.

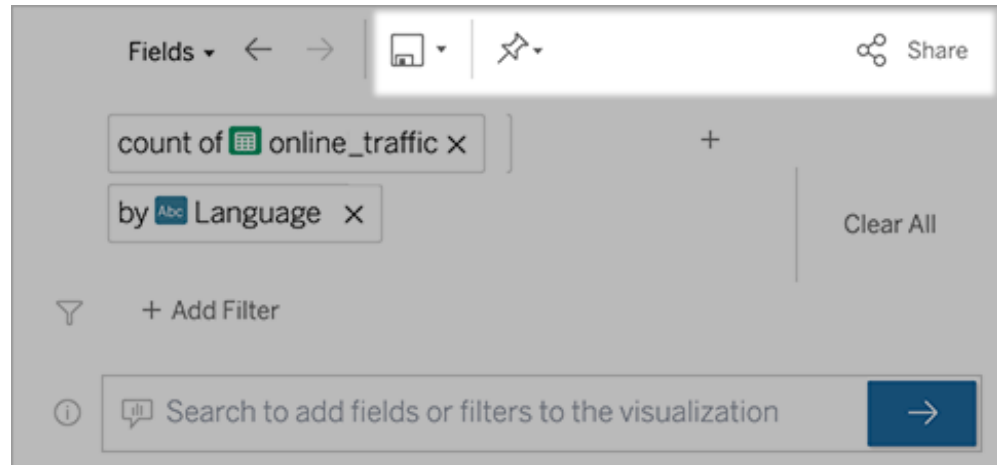

- 2.
3. Select a published data source previously connected to the workbook.
4. To use an existing lens, select it, and click **Use Lens**.

Or, to create a new lens, do one of the following:

- If there are no lenses for the data source, click **Go to Data Source Page**.
 - If lenses already exist, click the data source name at the bottom of the dialog.
5. (New lenses only) Complete the steps in Create or configure a lens page on your Tableau site.
 6. Under **Toolbar Options for Lens Users**, select the buttons you want available to users.
 - **Add Visualization to Pins** lets users [add to the Recommended Visualizations list](#), which appears just below the query box.
 - **Publish as Workbook** lets users [save visualizations as workbook sheets](#) to their Tableau site.
 - **Share Visualization** lets users [share via email, Slack, or a link](#).

In the lens, the publish (save icon), pin, and share options appear in the upper right corner:

7. (New lenses only) After you finish creating the lens, return to the Lens object in your dashboard, and click **Refresh**. Then select the new lens, and click **Use Lens**.

Apply a different lens to an Ask Data dashboard object

1. From the pop-up menu at the top of the object, choose **Configure**.

2. Go to Add an Ask Data lens to a dashboard, and repeat steps 2 onward.

Change a lens name, description, or project location

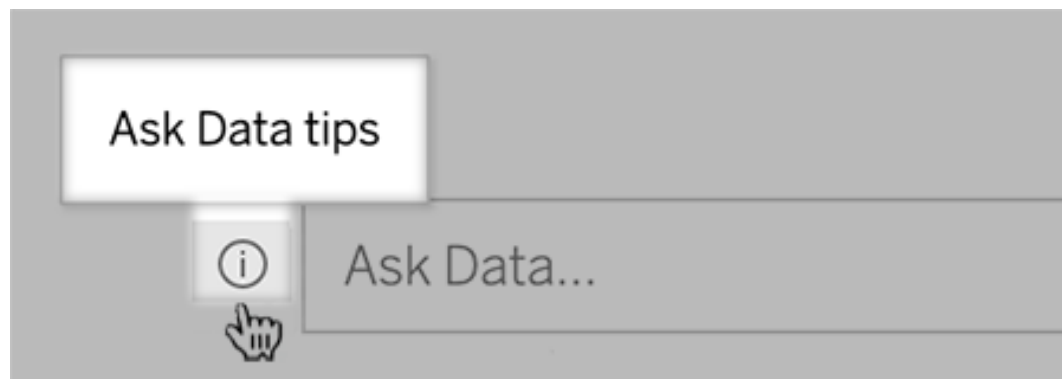

1. Navigate to the lens page on Tableau Cloud or Tableau Server.
2. To the right of the lens name at the top of the page, click the three dots (...), and choose **Edit Workbook**.
3. Click **Edit Lens Details**.

See how people use Ask Data with a lens

For data source owners and lens authors, Ask Data provides a dashboard that reveals the most popular queries and fields, the number of visualization results that users clicked, and other helpful information. Filters let you narrow data down to specific users and time ranges. These stats help you further optimize a lens to increase the success of your users.

Note: If you use Tableau Server, you can access this data in the Tableau Server Repository to create custom dashboards.

1. In Tableau Server or Tableau Cloud, navigate to a lens page.
2. To the left of the Ask Data text box, click the "Ask Data tips" icon.

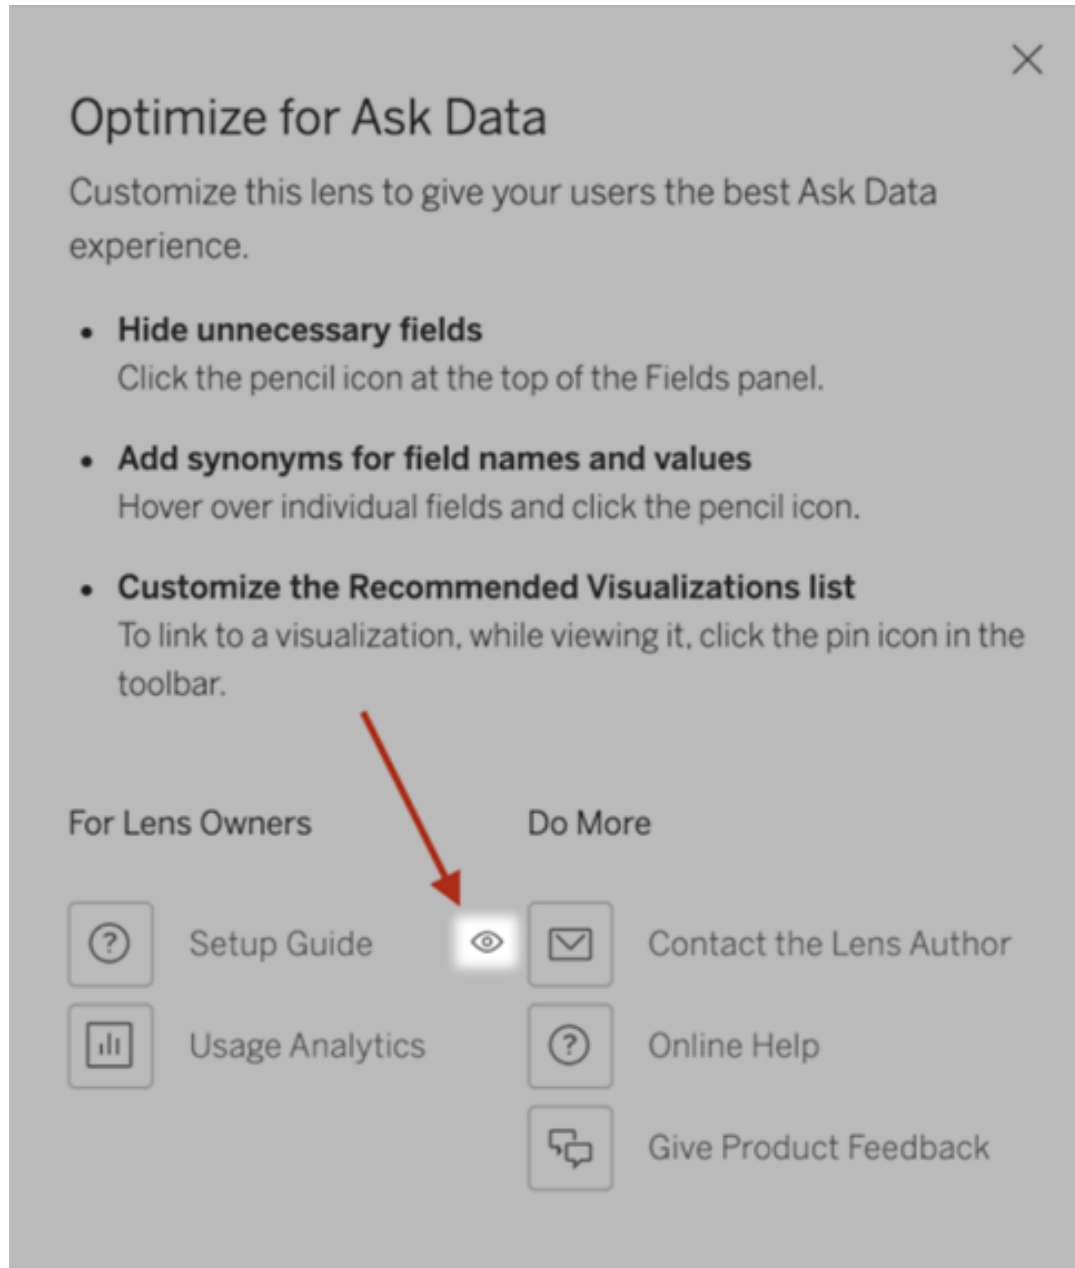

3. In the lower-left corner of the tips dialog, click **Usage Analytics**.

Let users email you questions about a lens

As a lens owner, you can allow users to email you with questions about data structure, expected results, and more. This option is on by default, but you can turn it off using the steps below.

1. In Tableau Server or Tableau Cloud, navigate to a lens page.
2. To the left of the Ask Data text box, click the "i" shown above in See how people use Ask Data with a lens.
3. At the bottom of the tips dialog, click the eye icon next to "Contact the Lens Author" to

enable or disable feedback.

Permissions for publishing and viewing lenses

For Ask Data objects in dashboards, no change to permissions should be required: by default, existing workbook authors can create lenses, and existing dashboard audiences can view

them. But for reference, here's a detailed outline of required lens permissions for both dashboards and direct access via a data source page.

To create and publish a lens, a user needs:

- The Creator or Explorer user role
- Lens Creation permission for the data source (inherited by default from the Connect permission)
- Write permission for the parent project to which the lens is published

To access and interact with a published lens, a user needs:

- The Viewer role or above
- Connect permission for the data source
- View permission for the lens

Note: By default, lens permissions like View reflect a project's permissions for workbooks. If Tableau administrators want to change default lens permissions, they can do so either individually for each project, or in bulk using the permissions API.

Disable or Enable Ask Data for a Site

Important changes coming for Ask Data and Metrics

Tableau's Ask Data and Metrics features will be retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau GPT and Tableau Pulse are reimagining the data experience](#).

Ask Data is enabled for sites by default, but Tableau administrators may disable it.

1. Go to the **General** site settings.
2. (Tableau Server only) In the **Web Authoring** section, select **Let users edit workbooks in their browser**.
3. In the **Availability of Ask Data** section, choose from these options:

- **Enabled** enables creation of Ask Data lenses for all published data sources.
- **Disabled** hides Ask Data throughout the site, while preserving information about previously created lenses so they can be restored if Ask Data is re-enabled.

Note: Beginning with version 2019.4.5, Tableau Server administrators can configure whether or not Ask Data is enabled by default.

Optimize Data for Ask Data

Important changes coming for Ask Data and Metrics

Tableau's Ask Data and Metrics features will be retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau GPT and Tableau Pulse are reimagining the data experience](#).

If you manage and publish data sources, here are some tips to help make users of Ask Data more successful. By spending a little extra time on this process, you'll open up data analysis to a wider range of people at your organization, helping them independently answer questions and gain deeper insights.

Optimize data in Ask Data

In the Data pane on the left of the Ask Data interface, data source owners can add synonyms for fields and exclude irrelevant values.

Changing settings at the data source or lens level

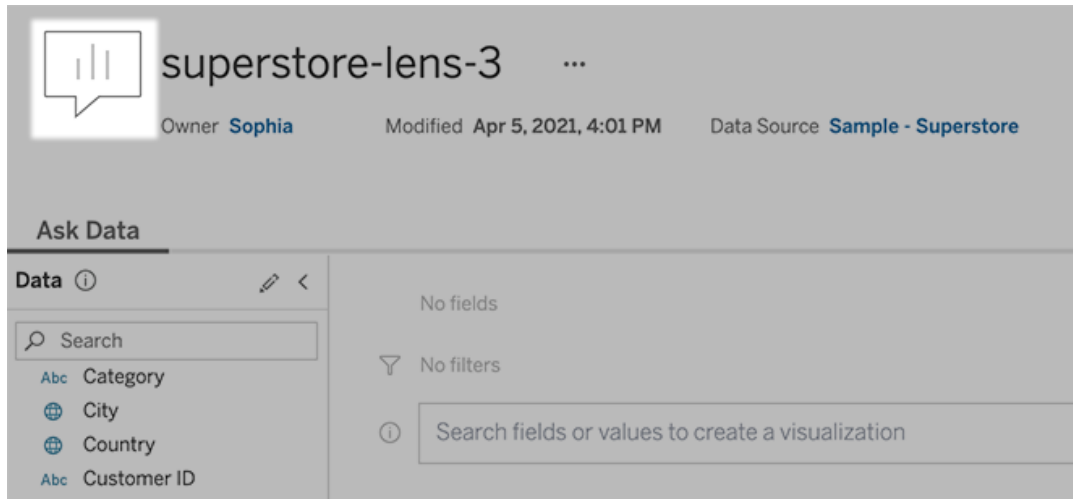

When changing settings in the Data pane for Ask Data, pay close attention to whether you're at the data source or lens level. (For more information, see [Create Lenses that Focus Ask Data for Specific Audiences](#).)

- At the data source level, you'll see the cylindrical data source icon in the upper left corner. Here, changes you make in the Data pane will apply by default to all subsequently created lenses.

Note: For extracts, two cylinders will appear.

- For an individual lens, you'll see the quotation icon in the upper left corner. Here, changes you make in the Data pane will apply to this lens alone.

Add synonyms for field names and values

People may not use the same terminology found in your data source, so data source owners and Tableau administrators can **add synonyms for specific data field names and values**. Synonyms you enter are available throughout your organization, making data analysis quicker and easier for everyone.

Exclude values of specific fields from search results

To improve the usability of search results in Ask Data, you can exclude the values of specific fields from indexing. Though Ask Data doesn't add non-indexed values to search results, the values still appear in visualization results when relevant. For example, if you don't index values from a "Product" field because they add unnecessary detail to search results, Ask Data can still display values such as "iPhone 12" in resulting data visualizations. And users can manually add non-indexed values to queries by surrounding them with quotation marks (for example, "Sales for Product containing "iPhone 12"").

Note: This field-level setting is ignored if **the value indexing setting for the data source** is set to Disabled. Field names and related synonyms are always indexed.

1. Go to the Ask Data tab for a data source or individual lens.
2. Hover over a data source field at left, and click the **Edit Field Details** icon (the pencil).

3. Deselect **Index field values**.

Either click the text box that appears to reindex the data source now, or let it reindex based on its regular indexing schedule.

Optimize data sources

To create the best experience for Ask Data users, optimize the original data source.

Note: Ask Data doesn't support multidimensional cube data sources, or non-relational data sources like Google Analytics, or data sources with a virtual connection.

Optimize indexing for Ask Data

Data source owners can change how often field values are indexed for Ask Data, optimizing system performance.

1. At the top of a data source page, click the Details icon:

2. In the Ask Data section, click **Edit**.

3. Choose an indexing option for field values:

- **Automatic** checks for changes every 24 hours and analyzes the data source if it is live, has had an extract refreshed, or has been republished. Choose this option for a data source frequently used with Ask Data, so it will be ready before users query it.
- **Manual** analyzes the data source only when Tableau creators manually trigger indexing on the data source page. Choose this option if the data source changes frequently but users query it with Ask Data only occasionally.

To trigger manual indexing, go to the data source page, click the circled “i” in the Data pane at left, and then click **Reindex Data Source**.

- **Disabled** analyzes only field names, not values.

4. Click **Save**

Use data extracts for faster performance

For improved performance and support for large data sets, use Ask Data with published extracts rather than live data sources. For more information, see [Create an extract](#).

Ensure that users can access the data source

To use Ask Data, users must have permission to connect to the individual data source. If a data source has row-level permissions, those permissions also apply to Ask Data, which won't recognize secure values or make related statistical recommendations.

Be aware of unsupported data source features

Ask Data supports all Tableau data source features except the following. If your data source contains these, Ask Data users won't be able to query related fields.

- Sets
- Combined fields
- Parameters

Anticipate user questions

Anticipate the kinds of questions your users will ask, and then optimize your data source for those questions using these techniques:

- Clean and shape data in **Tableau Prep** or a similar tool.
- **Join data** to include all fields users may have questions about in one table, improving performance.
- Add **calculated fields** that answer common user questions.
- Create **bins with appropriate sizes** for quantitative variables that users are likely to want to see as a histogram or another binned form.

Simplify the data

To make data easier to understand by both users and Ask Data, simplify the data source as much as possible during the data prep process.

1. Remove any unnecessary fields to improve performance.
2. Give each field a unique and meaningful name.
 - For example, if there are five field names that start with “Sales ...”, better distinguish them so Ask Data can properly interpret the term “sales”.
 - Rename “Number of records” to something more meaningful. For example, use “Number of earthquakes” in a data source where each record is an earthquake.
 - Avoid field names that are numbers, dates, or boolean (“true” or “false”) values.
 - Avoid names which resemble analytical expressions such as “Sales in 2015” or “Average Products Sold”.
3. Create meaningful **aliases for field values**, reflecting terms people would use in conversation.

Set appropriate field defaults

To help Ask Data analyze data correctly, ensure that default field settings reflect the content of each field.

- **Set data types** for text, time, date, geographic, and other values.
- **Assign the proper data role:** dimension or measure, continuous or discrete.
- For each measure, **assign appropriate default settings** in Tableau Desktop, such as color, sort order, number format (percentage, currency, etc.), and aggregation function. For example, SUM may be appropriate for “Sales”, but AVERAGE might be a better default for “Test Score”.

Tip: It's particularly helpful to set a default comment for each field, because these comments appear as informative descriptions when users hover over fields in Ask Data.

Create hierarchies for geographic and categorical fields

For time data, Tableau automatically creates hierarchies, which let users quickly drill up and down in vizzes (for example, from day to week to month). For geographic and categorical data, however, we recommend that you **create custom hierarchies** to help Ask Data produce visualizations that reflect the relationships between fields. Be aware that Ask Data won't show the hierarchies in the data pane.

Ask Data doesn't index hierarchy names, only names of fields within hierarchies. For example, if a geographic hierarchy named “Location” contains “Country” and “City” fields, users should enter “Country” and “City” in their questions for Ask Data.

Create a Tableau Data Story (English Only)

If you've ever written an executive summary of your Tableau dashboard, then you know it can be time-consuming. It takes time to choose which insights to share, and you have to rewrite your summaries each time the data is updated. Tableau Data Stories automatically generates narrative insights within your dashboard, saving time and surfacing relevant insights. As you

explore the vizzes in your dashboard, the stories written by Data Stories adjust, allowing you to dive deeper into data and identify key insights faster.

From where you're already working in Tableau, you can quickly add the **Data Story** object to your dashboard. And you can customize the terms and metrics used in your story, so Data Stories speaks the language used by your business.

Today, you can write and view a Tableau Data Story anywhere you use Tableau. After you create your story, you can also view your Data Story in Tableau Mobile. However, Data Stories aren't included if you export your dashboard, for example to a PDF.

Understand how Data Stories handles data

To write Data Stories, Tableau uses a service hosted in your Tableau Cloud or Tableau Server environment. When you Add a Tableau Data Story to a Dashboard or view a Data Story from a dashboard, Tableau sends associated worksheet data to the environment that you're logged in to (i.e., your Tableau Cloud site or your Tableau Server instance), using the security standards outlined in [Security in the Cloud](#) and [Security in Tableau Server](#). Data Stories can be written and viewed from anywhere you use Tableau.

Learn about how Data Stories are written

Tableau Data Stories is powered by rules-based templated natural language generation (NLG). Data Stories performs automated analytics to determine relevant and accurate facts about the underlying data—from basic calculations to more advanced statistics. To write a story, Data Stories uses a library of predefined language templates to synthesize these facts into natural language insights. Data Stories processes these templates at run-time, using the most up-to-date summary data from the Tableau worksheet it is connected to. You can leverage the [custom language feature](#) to generate your own language templates, add functions, and define business rules, helping you build a more relevant and contextual Data Story.

Note: Data Stories doesn't use generative AI, large language models (LLMs), or machine learning to write insights and stories.

Manage Data Stories for your site

Tableau administrators can choose whether Tableau Data Stories are available for their site. Data Stories are turned on by default.

1. Sign in to your Tableau site.
2. From the left pane, choose **Settings**.
3. From the **General** tab, scroll to the **Availability of Data Stories** section.
4. Choose whether you want to **Turn on** or **Turn off** Data Stories.

Note: If Data Stories are turned off, then turning the feature back on restores Data Stories that were already in dashboards.

Add a Tableau Data Story to a Dashboard

After you [Create a Dashboard](#), you can add the **Data Story** object to your dashboard to display insights about your viz that are written in natural language. Today, Tableau Data Stories are written in English only and are available in Tableau Cloud, Tableau Server (version 2023.1 and later), and Tableau Desktop. There is no data size limit when creating **Data Stories**. However, story generation times out after 45 seconds if it's trying to analyze a lot of data. We recommend using **Data Stories** with visualizations that have 1,000 or fewer data points.

Note: Tableau Data Stories opens in a pop-up window, so be sure to allow pop-ups. If you're using full screen mode, then Data Stories can open in a new tab.

1. Drag the **Data Story** object into your Tableau dashboard. If you haven't already, add a sheet to your dashboard to use Tableau Data Stories.

2. In the Data Story dialog box, configure your story by first choosing the worksheet to write about. When you click **Next**, Tableau sends all associated workbook data to the

Tableau Cloud or Tableau Server instance that you are logged in to.

4. Choose the type of story that best describes your data:

Configure

Views Fields **Story**

Choose the option that best describes your data. You can see a preview in the container.

☒ **Discrete (best fit)** For qualitative values such as names or dates.

☐ **Continuous** For quantitative values over time.

☐ **Percent of Whole** For proportions of a whole.

☐ **Scatter Plot** For relationships between numerical variables.

Back Done

Discrete is best for qualitative values such as names or dates, such as in bar or column charts.

Continuous is best for quantitative values over time, such as a plotted in a line chart.

Percent of Whole is best for proportions of a whole, such as a pie chart.

Scatter Plot is best for relationships between numerical values, such as a scatter plot chart.

5. Click **Done**.

To filter your Data Story by clicking different sections on your visualization, open the menu on your visualization and click **Use as filter**.

After your story is generated, click **Settings** at the top of your **Data Story** object for a guided experience that helps you personalize and contextualize your story. For more information, see [Configure Settings for a Tableau Data Story](#).

Note: If you experience a discrepancy in your Tableau Data Story (for example, if the numbers in your story are different than in your visualization), it may be caused by way your visualization is set up. Try creating a new visualization on a different sheet, and then add a new Data Story with the Use a hidden sheet technique to uncover the underlying issue.

Choose the Right Story Type for Your Tableau Data Story

When you Add a Tableau Data Story to a Dashboard, it's important to choose the right type of story for your data. Do you want your story about trends over time? Or do you want your story about two values that you're comparing? To help you tell the right story, this topic describes the different types of stories, including an example of each story type.

Continuous

Continuous stories are best for analyzing trends or progress over time.

When you create a continuous story, it includes content for performance, segments, volatility, and trend lines. The story also includes contribution analysis and correlation for stories that use more than one dimension. To use a continuous story, your worksheet must have:

- 1 dimension that has between 1-10 measures
- 2 dimensions and up to 3 measures

The following example is a continuous story for a line chart that has a single dimension and multiple measures:

Discrete

Discrete stories are best for comparing values and understanding the distribution of data in each value. When you create a discrete story, the story includes content about the distribution and groupings or clusters across the data. And the story includes contribution analysis for worksheets that use multiple dimensions.

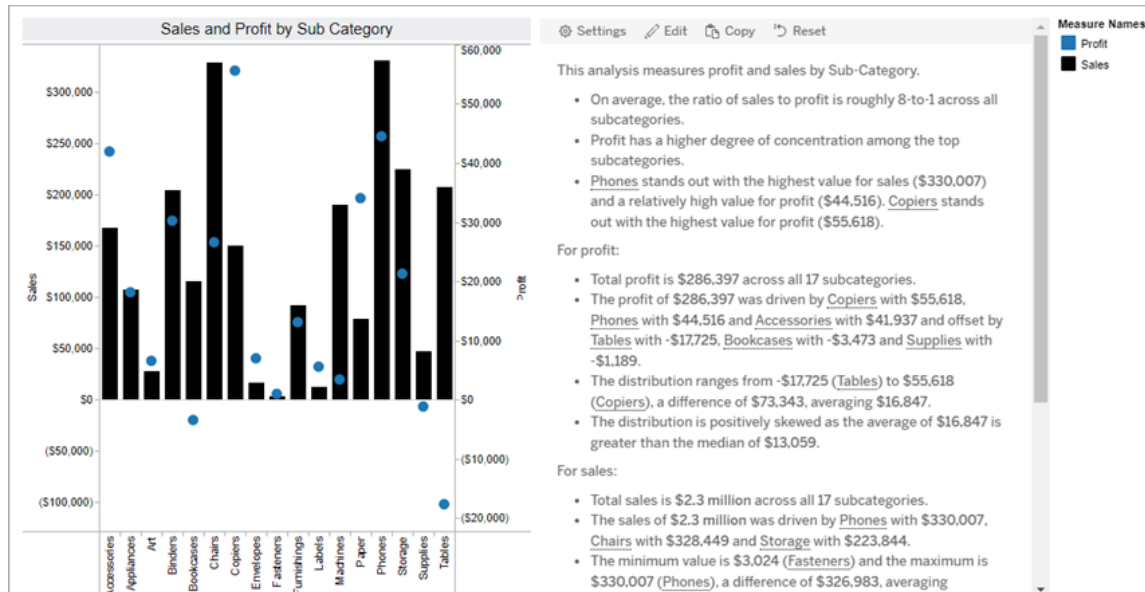

Consider using a discrete story when you want to:

- Understand drivers of your key performance indicators (KPIs) in sales reports.
- Identify and understand outliers quickly during data discovery.
- Identify trends that aren't easily observable in the visual when performing an audit.
- Uncover complex utilization insights instantly for geographic analysis.
- Identify and call out key relationships, for example, between sales and profit.

To use a discrete story, your worksheet must have:

- 1 dimension that has between 1-10 measures
- 2 dimensions and up to 3 measures

The following example is a discrete story for a bar chart that has a single dimension and two measures:

Percent of whole

Percent of whole stories are best for pie charts. To use a percent of whole story, your worksheet must have:

- 1 dimension
- 1 measure

The following example is a percent of whole story that uses a pie chart with a single dimension and a single measure:

Scatter plot

Scatter plot stories are best for understanding the relationship between two measures. When you create a scatter plot story, the story includes content about the relationship (regression) between two measures. And the story includes content about groups (clusters) within the data, when they exist.

Consider using a scatter plot story when you want to:

- Call out relationships between two measures to identify impact (regression analysis).
- Identify and understand outliers that are above or below defined thresholds.
- Analyze how your data is distributed.

To use a scatter plot story, your worksheet must have:

- 1 dimension
- 2 or 3 measures

Note: When you create your scatter plot story, the first measure you select is treated as the independent variable and the second measure is the dependent variable.

The following example is a scatter plot story that uses a scatter plot that has a single dimension and two measures:

Configure Settings for a Tableau Data Story

After you Add a Tableau Data Story to a Dashboard, you can configure and edit your Tableau Data Story so it's tailored to your needs—use language specific to your data, specify which analytics are written about, and customize how your Tableau Data Story is displayed.

Configure Tableau Data Story Settings: Analytics

Within your Tableau Data Story, you can choose which analytics to write about and when those analytics are written about. Different types of analytics are available depending on your story type and how many dimensions and measures your story has. However, analytics aren't currently supported for scatter plot story types. For more information, see [Choose the Right Story Type for Your Tableau Data Story](#).

Configure analytics for your story

1. Add a Tableau Data Story to a Dashboard.
2. From your dashboard, click the **Settings** icon at the top-left corner of your **Data Story** object.
3. In the Data Story dialog box, click the **Analytics** tab.
4. Click the switches to turn on different types of analytics.

5. For **Segments** and **Trend line**, expand **Settings** to set thresholds for performing those analytics.
6. Click **Save**.

Understand different types of analytics

Correlation

Use **Correlation** to identify true statistical correlations between two series. If you have more than two series, then all combinations are analyzed for correlations. For example, you might turn on **Correlation** to identify when two products are often purchased together.

Clustering

Use **Clustering** to identify distinct groups of data points (clusters) using a single statistical analysis. For example, you might turn on **Clustering** to identify when a product is very popular in a specific geographic region.

Distribution

Use **Distribution** to rank data points relative to each other using nonstatistical observations, such as mean, median, skew, etc. For example, you might turn on **Distribution** to identify which product has the highest profit ratio.

Segments

Use **Segments** to highlight noteworthy changes to data points within a series. First, set the minimum percentage of change that you want to be written about in a segment. Changes that fall below your defined threshold aren't written about. For example, if you set your segment threshold for changes that are greater than 60%, then your story doesn't write about a trough in a time series that features a 30% decrease.

After you've set your threshold, choose whether to **Apply formatting**, and set the minimum percentage of change that you want formatted.

Trend line

Use **Trend line** to calculate a linear best fit line and identify data that falls within a defined percentage of confidence. Data that has high variability has a lower confidence level than data that's more consistent, and that confidence level affects whether trend lines are written about. You can use trend lines for stories that have one dimension and one measure, or you can use trend lines in a drilldown. For more information about drilldowns, see [Configure Tableau Data Story Settings: Narrative](#).

Set the minimum percentage of confidence for your trend line. If you set your threshold at 95%, but a trend line could be drawn at 90% confidence, then your story doesn't write about trend lines. After you've set your threshold, choose whether to **Apply formatting**. Then set the minimum percentage of change that you want formatted.

Tableau Data Stories about trend lines communicate the absolute change over a period. The story written about your trend line varies depending on the level of verbosity you set for your story. If your story uses high verbosity, then your story writes about the R-squared value, which is a statistical concept that quantifies how well your data fits the trend line. For more information about verbosity settings, see [Configure Tableau Data Story Settings: Narrative](#).

Within the **Trend line** settings, you can also choose how many periods into the future for which you want your story to write predictions. When you use predictions, your story uses the slope and intercept of the trend line to calculate predicted values for future periods. The confidence of the prediction adds upper and lower bounds to the confidence threshold you set for trend lines. You can use predictions when your story has at least 30 data points that are linear.

Volatility

Use **Volatility** to analyze standard deviations over time. For example, use **Volatility** when you want your story to write about values that fall outside the average range for your data.

Break down how analytics are used to generate stories

At this point, you might be wondering how the analytics for different story types work. Let's take a look at an example for each story type and break down each sentence in the story.

Understand analytics for discrete stories

Because continuous stories measure trends over time, Data Stories writes about performance, progression, averages, totals, streaks, volatility, segments, and predictions.

The following example of a continuous story is about sales per month:

This analysis measures Sales by month.

- Average Sales was **\$47,858** across all **48** months.
- The minimum value was **\$4,520** (February 2014) and the maximum was **\$118,448** (November 2017).
- Sales increased by **489%** over the course of the series but ended with a downward trend, decreasing in the final month.
- The largest single increase on a percentage basis occurred in March 2014 (+**1,132%**). However, the largest single increase on an absolute basis occurred in September 2014 (+**\$53,868**).
- Sales experienced cyclical, repeating each cycle about every **12** months. There was also a pattern of smaller cycles that repeated about every **three** months.
- Sales had a **significant positive peak between October 2014 (\$31,453) and February 2015 (\$11,951), rising to \$78,629 in November 2014.**
- The **overall linear trend of the series rose at \$902 per month** for an absolute change of **\$42,394** over the course of the series.

Example story	Story breakdown
<ul style="list-style-type: none">• Average Sales was \$47,858 across all 48 months.• The minimum value was \$4,520 (February 2014) and the maximum was \$118,448 (November 2017).	The first two sentences use average and range functions to write about the average, maximum, and minimum values across the period you're analyzing.
<ul style="list-style-type: none">• Sales increased by 489% over the course of the series but ended with a downward trend, decreasing in the final month.	The third sentence is about overall performance of the measure over the period. For example, a sentence can be about whether sales increased, decreased, or trended differently during a specific period.

<ul style="list-style-type: none"> The largest single increase on a percentage basis occurred in March 2014 (+1,132%). However, the largest single increase on an absolute basis occurred in September 2014 (+\$53,868). 	<p>The fourth sentence uses progression analysis. This sentence writes about the largest increase and decrease based on the measure during the period using both a percentage basis and absolute basis.</p>
<ul style="list-style-type: none"> Of the three series, the strongest relationship was between Corporate and Home Office, which had a moderate positive correlation, suggesting that as one (Corporate) increases, the other (Home Office) generally does too, or vice versa. 	<p>This sentence is a Correlation insight. This type of analytic insight writes about notable correlations between different series in your data.</p>
<ul style="list-style-type: none"> Sales experienced cyclical, repeating each cycle about every 12 months. There was also a pattern of smaller cycles that repeated about every three months. Sales had a significant positive peak between October 2014 (\$31,453) and February 2015 (\$11,951), rising to \$78,629 in November 2014. 	<p>This sentence is a Segment insight. This type of analytic insight writes about noteworthy increases and decreases over time.</p>
<ul style="list-style-type: none"> The overall linear trend of the series rose at \$902 per month for an absolute change of \$42,394 over the course of the series. If this trend continued for the next one month, Sales is predicted to be about \$69,958. 	<p>This sentence is a Trend line insight. This type of insight writes about how well trends fit your data with a certain percentage of confidence, and trend lines allow you to make predictions based on historic trends.</p>

Understand analytics for discrete stories

Because discrete stories allow you to compare values and understand the distribution of the data, the story writes about distribution, averages, totals, and groupings or clusters across the data.

The following example of a discrete story is about sales by product:

This analysis measures Sales by product.

- Total Sales is **\$2.3 million** across all **17** products.
- The Sales of **\$2.3 million** was driven by Phones with **\$330,007**, Chairs with **\$328,449** and Storage with **\$223,844**.
- The distribution ranges from **\$3,024** (Fasteners) to **\$330,007** (Phones), a difference of **\$326,983**, averaging **\$135,129**.
- The distribution is positively skewed as the average of **\$135,129** is greater than the median of **\$114,880**.
- Sales is somewhat concentrated with **eight** of the **17** products (**47%**) representing **78%** of the total.
- The top **two** products represent over a quarter (**29%**) of overall Sales.
- Phones (**\$330,007**) is more than **two** times bigger than the average across the **17** products.

Example story	Story breakdown
<ul style="list-style-type: none">• Total Sales is \$2.3 million across all 17 products.	The first sentence calculates the total value of your measure.
<ul style="list-style-type: none">• The Sales of \$2.3 million was driven by <u>Phones</u> with \$330,007, <u>Chairs</u> with \$328,449, and <u>Storage</u> with \$223,844.	The second sentence writes about the dimension drivers. In this example, the dimension drivers are the products that contributed the most to total sales.
<ul style="list-style-type: none">• The distribution is positively skewed as the average of \$135,129 is greater than the median of \$114,880.• Sales is relatively concentrated with 78% of the total represented by eight of the 17 products (47%).	The third and fourth sentences analyze the distribution of the data. This analyzes the averages, medians, concentration of data (if any exist), and how the data is skewed. This helps identify how balanced these grouped variables are compared to one another.
<ul style="list-style-type: none">• The top two products combine for over a quarter (29%) of overall Sales.	This sentence uses Clustering to write about measures that can be grouped. This

	helps identify whether there are distinct groups that stand out in the data.
<ul style="list-style-type: none"> • <u>Phones (\$330,007)</u> is more than two times bigger than the average across the 17 products. 	The final sentence writes about notable outliers.

Understand analytics for scatter plot stories

Scatter plot story types are best used to understand the relationship between two measures, and for that reason, scatter plot stories require 2–3 measures. The scatter plot analysis writes about the relationship (regression) between two measures, and it writes about groups (clusters) within the data, if they exist.

The following example of a scatter plot story is about profit and sales across a dimension:

This analysis measures profit, quantity and sales across 793 customer.	
<ul style="list-style-type: none"> • As quantity increased and profit increased, sales increased based on the data provided. Specifically, when quantity increased by 1, sales increased \$49.55, and when profit increased by \$1.00, sales increased \$1.20. • Few customers deviated from this general relationship, indicating a good fit. • When organized into groups of similar profit, quantity and sales values, one distinct group stands out. There were 651 customers that had values of profit between -\$6,626 and \$1,488, quantity between 2 and 122 and sales between \$4.83 and \$5,690. • <u>Tamara Chand</u>, <u>Raymond Buch</u> and <u>Sanjit Chand</u>, among others were outliers with high profit and sales values. <u>Sean Miller</u> stood out with a low profit and high sales value. • The minimum value for profit is -\$6,626 (<u>Cindy Stewart</u>) and the maximum value is \$8,981 (<u>Tamara Chand</u>), a difference of \$15,608. The average profit per customer is \$361 and the median is \$228. • The minimum value for quantity is 2 (<u>Anthony O'Donnell</u>) and the maximum value is 150 (<u>Jonathan Doherty</u>), a difference of 148. The average quantity per customer is 47.76 and the median is 44. • The distribution of sales ranges from \$4.83 (<u>Thais Sissman</u>) to \$25,043 (<u>Sean Miller</u>), a difference of \$25,038. The average sales per customer is \$2,897 and the median is \$2,256. 	

Example story	Story breakdown
<ul style="list-style-type: none"> • As quantity increased and profit 	The first two sentences are powered by

<p>increased, sales increased based on the data provided. Specifically, when quantity increased by 1, sales increased \$49.55, and when profit increased by \$1.00, sales increased \$1.20.</p> <ul style="list-style-type: none"> Few customers deviated from this general relationship, indicating a good fit. 	<p>regression analytics. Regression shows how one measure affects another. Notice that in the first sentence, the story has identified a relationship between profit and sales.</p>
<ul style="list-style-type: none"> When organized into groups of similar profit, quantity and sales values, one distinct group stands out. There were 651 customers that had values of profit between -\$6,626 and \$1,488, quantity between 2 and 122 and sales between \$4.83 and \$5,690. 	<p>The third sentence is derived from clustering. Clustering analytics tries to identify key groups or clusters across all the variables in the data.</p>
<ul style="list-style-type: none"> <u>Tamara Chand</u>, <u>Raymond Buch</u>, and <u>Sanjit Chand</u>, among others were outliers with high profit and sales values. Sean Miller stood out with a low profit and high sales value. 	<p>The fourth sentence is written about outliers—values that fall significantly above or below the average.</p>
<ul style="list-style-type: none"> The minimum value for profit is -\$6,626 (<u>Cindy Stewart</u>) and the maximum value is \$8,981 (<u>Tamara Chand</u>), a difference of \$15,608. The average profit per customer is \$361 and the median is \$228. The minimum value for quantity is 2 (<u>Anthony O'Donnell</u>) and the maximum value is 150 (<u>Jonathan Doherty</u>), a difference of 148. The average quantity per customer is 47.76 and the median is 44. The distribution of sales ranges from 	<p>The remaining sentences for scatter plot stories use range and average analysis to write insights.</p>

<p>\$4.83 (Thais Sissman) to \$25,043 (Sean Miller), a difference of \$25,038. The average sales per customer is \$2,897 and the median is \$2,256.</p>	
--	--

Understand analytics for percent of whole stories

Percent of whole story types are best for understanding what part of a whole a dimension or measure represents.

The following example of a percent of whole story is about sales by segment:

<p>This analysis measures sales by segment as a percentage of the whole.</p> <ul style="list-style-type: none">• Total sales is \$2.3 million across all three segments.• The minimum value is 19% (Home Office) and the maximum is 51% (Consumer), a difference of 32%.• The average sales per segment is \$765,734.
--

Example story	Story breakdown
<ul style="list-style-type: none">• Total SUM(Sales) is 2.3 million across all three entities.	The first sentence calculates the total value of your measure.
<ul style="list-style-type: none">• The SUM(Sales) of 2.3 million was driven by Consumer with 1.2 million, Corporate with 706,146 and Home Office with 429,653.	The second sentence writes about drivers. In this example, the drivers are segments that contributed the most to total sales.
<ul style="list-style-type: none">• The minimum value is 429,653 (Home Office) and the maximum is 1.2 million (Consumer), a difference of 731,748, averaging 765,734.	The final sentence analyzes the distribution of the data.

Configure Tableau Data Story Settings: Characteristics

Within your Tableau Data Story, you can configure the characteristics settings to give context to your data, so you get more insightful stories. For example, in your story you can specify that in the context of sales, a higher number is good. But in the context of customer complaints, a higher number is bad.

Use dimension and measure characteristics

Your story and number formatting adjusts based on what the measure is. By default, your story writers all measure values as numbers, and your story won't perform any additional calculations or apply any special rendering rules.

1. Add a Tableau Data Story to a Dashboard.
2. From your dashboard, click the **Settings** icon at the top-left corner of your Data Story object.
3. In the Data Story dialog box, click the **Characteristics** tab.
4. Configure your formatting, such as number type, decimal places, and negative values.
5. Click **Save**.

Learn more about measure characteristics

Formatting

If values are formatted as **Percentages**, then the story writes about percentage point differences, rather than percent changes as a story would for number values. When you format a number as a **Percentage** in the **Characteristics** tab, the **Data Story** multiplies the value of the number by 100 to create the percentage that shows in your story.

If values are formatted as **Currency**, then you can specify your preferred currency. You can also specify how you want large values (numbers greater than one million) formatted, for example \$1.3 million instead of \$1,300,000.00.

For both **Numbers** and **Currency**, you can specify how you want large values and negative values to be written about. If you choose to have negative values written about in parentheses, you might see nested parentheses in your story when the negative value is written about in a parenthetical phrase.

When you choose **Number** formatting, you can also specify whether you want numbers less than or equal to 10 to be spelled out (rather than using a numeral) in your story.

For decimal places, **Dynamic** is the default option. This means that the story rounds to different decimal places depending on how large or small the number is. If the percent value is less than 10, then the number has two decimal places. If the percent value is greater than 10, then the number rounds to the nearest whole number. You can also specify how many decimal places you want used, which is used consistently throughout your story.

Content

You can assign meaning to larger values. For example, larger values for sales are good, but larger values for losses are bad.

In addition, you can choose how to aggregate values by sum or average. It's a best practice to choose the same aggregation method that you're using in the viz. For ratio measures, choose **Average** and then define the ratio by selecting the component measures of that ratio measure. Measures that are components of a ratio must be summable.

Content

Assign meaning to larger values.

☒ Good ☐ Neutral ☐ Bad

Choose how to aggregate SUM(Quantity). ⓘ

☐ Sum ☒ Average

SUM(Quantity) is a ratio.

☒ Ratio

SUM(Quantity) is a ratio of: ⓘ

SUM(Profit) / SUM(Sales)

For cumulative measures (available for continuous stories only), choose **Sum** and then specify that the measure is already cumulative. Continuous stories write about the total of the measure across the series.

Sorting

To sort dimension values, click the arrow up/down icon to sort based on the oldest or newest time values in your dimension.

Note: Sorting dimension values is available for only continuous stories.

Configure Tableau Data Story Settings: Display

You can configure how the text in your Tableau Data Story is displayed, such as font color and size. You can also choose whether your story uses bulleted lists or paragraphs.

Configure the display for your story

1. Add a Tableau Data Story to a Dashboard.
2. From your dashboard, click the **Settings** icon at the top-left corner of your Data Story object.
3. In the Data Story dialog box, click the **Display** tab.
4. Choose whether you want your story structure to be **Bullets** or **Paragraphs**.
5. Choose your **Font Size**.
6. Pick colors to represent good and bad changes (available for continuous stories).
7. Choose whether to use **Dynamic Ordering**.
8. Choose whether to use a **Condensed View**.
9. Click **Save**.

Understand when to use story display settings

To use color, your story must be continuous. When using color, you can choose colors from the palette to represent good changes and bad changes. For your story to know whether a change is good or bad, you must assign meaning to larger values in the **Characteristics** tab. For more information, see [Configure Tableau Data Story Settings: Characteristics](#). After you configure your display, the styles and colors are applied in your story based on thresholds for trend line or segment analytics.

If you turn on **Dynamic Ordering**, then the insights for measures in a story are dynamically ordered from the best to the worst average value. If you already have an order you want to maintain, turn off **Dynamic Ordering**.

If you turn on **Condensed View**, then additional space is removed from your story. This is helpful if you don't have much extra space in your dashboard or when you have multiple Data Story objects in a dashboard.

Configure Tableau Data Story Settings: Drivers

Hypothetically, let's say your month-over-month sales increased significantly. What drove that increase in sales? And what might have detracted from (offset) those increased sales? Setting up drivers in your Data Story can answer those questions.

In Data Stories, drivers contribute toward a total value. Offsetters detract from a total value. You'll find insights about drivers and offsetters in discrete and continuous stories. And these insights make it easy to understand exactly what's going on in the data and why.

Set dimension drivers

1. Add a Tableau Data Story to a Dashboard.
2. From your dashboard, click the **Settings** icon at the top-left corner of your Data Story object.
3. In the Data Story dialog box, click the **Drivers** tab.
4. From the **Dimension Drivers** section, select the type of driver that has the greatest impact on your analysis:
 - For **Count**, set the maximum number of contributors and offsetters.
 - For **Individual %**, set thresholds for writing about individual contributors and offsetters.
 - For **Cumulative %**, set thresholds for writing about contributors and offsetters based on their collective value.
5. Click **Save**.

Understand dimension driver types

- **Count** specifies the number of entities (contributors and offsetters) called out in your story. For example, use **Count** to see the top three contributors and offsetters in your data.

- **Individual %** sets a threshold, and values higher than that threshold are included in your story. For example, use **Individual %** to specify that you want to write about only entities that represent more than 5% of the total value.
- **Cumulative %** sets a percentage threshold of the total value that included entities collectively account for. For example, use **Cumulative %** to specify that you want to write about the entities that contributed to at least 90% of that total value. In this example, entities are written about in order of magnitude until the cumulative value of those entities account for 90% of the total value.

Use secondary contributors

To use secondary contributors, you must have a second dimension that isn't time. When you use secondary contributors, each driver that is written about also has details about and drivers for its secondary contributor. For example, if you are analyzing store sales, a secondary contributor would be a class within a department. Secondary contributors allow for deeper analysis. But secondary contributors can also contain a lot of information to fit into a single sentence in your story.

Set metric drivers

For measures that are composed of other subcategory measures, driver analysis can explain the impact that each measure had on the top-level value. For example, material costs and operating costs contribute to total cost.

To use metric drivers, you must have multiple measures for metric analysis. Then, you can specify the relationships between each measure.

1. Add a Tableau Data Story to a Dashboard.
2. From your dashboard, click the **Settings** icon at the top-left corner of your Data Story object.
3. In the Data Story dialog box, click the **Drivers** tab.
4. From the **Metric Drivers** section, first choose the measure that is a subcategory of another measure.
5. Then, choose the measure that is the primary category.
6. Click **Save**.

Tip: The verbosity setting also applies to drivers. By changing your story's verbosity setting, you can adjust the way insights are written. If you use high verbosity, then you'll see more information in parentheses. If you use low verbosity, then you'll get a more concisely written insight about your drivers. For more information, see [Configure Tableau Data Story Settings: Narrative](#).

Configure Tableau Data Story Settings: Narrative

You can customize the narrative settings of your Tableau Data Story. Specifically, you can specify the verbosity and level of analytical detail in your story, and you can add terms that are unique to your data. These settings help you write a story that uses the right language and speaks to the right level of detail for your dashboard.

Set verbosity

Verbosity specifies the length and analytical detail written in your story. If you choose high, then your story has longer insights with more analytic analysis. If you choose low, then your story is more concise with fewer details.

If you allow viewers to change verbosity, then viewers of published dashboards can change the level of verbosity in the Data Story object. This is helpful when your dashboard is used by a broader audience with viewers who want varying levels of detail from your story.

Set drilldowns

A drilldown includes two dimensions, and drilldowns describe figures associated with each dimension of your dashboard.

Let's say you have a dashboard that has monthly sales by product category. Your story is configured to write about both the **Time** and **Category** dimensions. In this case, this story includes an insight for each Category that describes its performance in and across the **Time** dimension.

By setting the maximum number of drilldowns, you can control how many insights are included in your story. Drilldown insights are also ranked based on the meaning assigned to the measure characteristics. As the number of drilldowns is reduced, the lowest performing measures (measures that are assigned a Bad meaning) are eliminated.

Add dimension terms

By adding terms, you can define the way each of your measures and dimensions are labeled and referenced in your story.

1. Add a Tableau Data Story to a Dashboard.
2. From your dashboard, click the **Settings** icon at the top-left corner of your Data Story object.
3. In the Data Story dialog box, click the **Narrative** tab.
4. Expand the dimension to see how it will be written about in both singular and plural form.
5. Click **Add Term** to add another variation for your story to use to describe your dimension.
6. Click **Save**.

Your story uses (at random) the terms you've added when writing about a dimension.

Manage measure labels

Similarly to dimensions, you can manage labels used for measures in your story.

1. From the **Narrative** tab, expand the measure to see its label.
2. Enter the new label that you want used for your measure.
3. Click **Save**.

Configure Tableau Data Story Settings: Relationships

The **Relationships** setting allows you to assign relationships between measures in a Tableau Data Story that has multiple measures. To configure Relationships, your story must have one dimension and multiple measures. For more information, see [Create Custom Measure Relationships in Your Tableau Data Story](#).

There are two types of relationships:

- Actual vs. Benchmark
- Current/Most Recent vs Previous Period

Use **Actual vs. Benchmark** when you want to know if you're performing above or below your performance benchmarks, for example, when performing quota reporting. This type of relationship is also helpful for identifying data points that require additional analysis because they're significantly above or below your benchmark. To use **Actual vs. Benchmark**, the measures you're comparing must have the same value type.

Use **Current/Most Recent vs. Previous Period** when you want to see if your key performance indicators (KPIs) are increasing, decreasing, or remaining consistent over time. To use **Current/Most Recent vs. Previous Period**, you must use a discrete story type. For more information, see [Choose the Right Story Type for Your Tableau Data Story](#).

Additionally, you can use **Actual vs. Benchmark** and **Current/Most Recent vs. Previous Period** relationships simultaneously. Measures in your viz that aren't part of the configured relationships are written about in separate paragraphs.

Create Actual vs. Benchmark relationship for continuous or discrete stories

Use the **Actual vs. Benchmark** relationship when one measure is a benchmark for other measures. For example, you could compare actual sales to a sales target, so your story writes insights about whether you outperformed or underperformed your goal. When you use this type of relationship, the story removes unnecessary content and focuses on what's most important—comparing a metric to its associated benchmark.

1. Add a Tableau Data Story to a Dashboard.
2. From your dashboard, click the **Settings** icon at the top-left corner of your Data Story object.
3. In the Data Story dialog box, click the **Relationships** tab.
4. Check the box for **Actual vs. Benchmark**.
5. First, select the measure that is the benchmark.
6. Then, select the measure that you want to compare against the benchmark.
7. Click **Save**.

Create Current/Most Recent vs. Previous Period relationship

Use the **Current/Most Recent vs. Previous Period** relationship to compare the performance of two measures over a period. For example, you could compare two products to see which product generated the most revenue over the last year.

1. Add a Tableau Data Story to a Dashboard.
2. From your dashboard, click the **Settings** icon at the top-left corner of your Data Story object.
3. In the Data Story dialog box, click the **Relationships** tab.
4. Check the box for **Current/Most Recent vs. Previous Period**.
5. First select the measure for the previous period.
6. Then, select the measure for the current period.
7. Enter the label for the period that you're measuring, for example, year.
8. Choose the number of periods to measure.
9. Click **Save**.

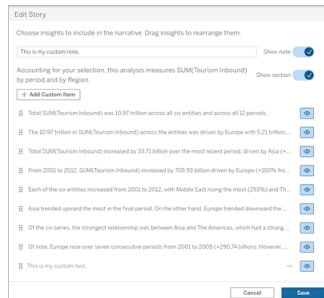

Customize Your Tableau Data Story

You can use custom language, tailored to your audience, to supplement your Tableau Data Stories with insights specific to your business. Identify the analytics and data from the Data

Story that matters most to your audience, and use your own language to create the most impactful story. As with the overall Tableau Data Story, data and variables used in custom content are dynamic, adjusting along with the dashboard.

Add your own insights

1. In your **Data Story**, click **Edit** to open the Edit dialog box.
2. Find the section you want to write about and click **Add Custom Item**.

3. Enter your custom text in the field that appears.
4. Click **Save**.

Add headers and footers

You can insert custom text at the top and bottom of your **Data Story**. With headers and footers, you can add your own qualitative analysis to stories, include additional explanations of data trends, or append legal and privacy disclaimers.

1. In your **Data Story**, click **Edit** to open the Edit dialog box.
2. Click the **Show note** switch.
3. Enter your custom note.

4. Click **Save**.

Your note now shows at the top or bottom of your **Data Story**.

Add functions

Using a function in your Data Story is a great way to customize your story and find the insights that are most important to you and your business.

For example, if you want to know the average sum of tourism revenue over a period, select Average as your function and then designate the measure as SUM(Tourism Inbound). This returns the average sum of inbound tourism.

1. In your **Data Story**, click **Edit** to open the Edit dialog box.
2. Click the menu in the right side of the box and select **Add Function**.

3. Select a Data Story Function and fill in the required fields.

4. Click **Add to Section**.
5. Click **Save**.

The custom content now shows in your Data Story.

Add conditions

For each custom sentence you write, you can add a condition that determines whether the sentence renders in your **Data Story**. If the condition is met, the custom sentence appears in your story. If the condition isn't met, the custom sentence doesn't appear.

You can apply multiple conditions to each custom sentence, and the conditions can be combined using the **Any** or **All** buttons within the Add a condition dialog box.

Conditional statements are most often used with numerical comparisons, but the function also supports string matching using the equal (=) or not equal (!=) symbols.

1. In your Data Story, click **Edit** to open the Edit dialog box.
2. Enter your custom sentence.
3. Click the menu on the right side of the box and select **Add Condition**.
4. Define the custom function to be used to inform the conditional logic. In this example, the sentence "We have met our quota" shows if the Sum of Tourism Inbound is greater than 5 trillion.

5. Click **Add to Section**.
6. Click **Save**.

The custom sentence now appears in your Data Story only if the conditions are met.

Duplicate custom content

You can easily duplicate custom content added to your Data Story, making it easier to build different variations of a sentence. We recommend copying a fully built custom sentence when applying thresholds, building in language variation, and creating different logical variations.

1. In your Data Story, click **Edit** to open the Edit dialog box.
2. Create a custom sentence, complete with functions and conditions, if desired.

3. In the completed sentence box, Click the menu in the right side of the box and select **Duplicate**.

4. Click into your duplicated sentence, update as desired, and click **Add to Section**.
5. Click **Save**.

When you copy a sentence, all functions and conditional statements also copy over. The copied bullet appears directly below the original bullet in the same section.

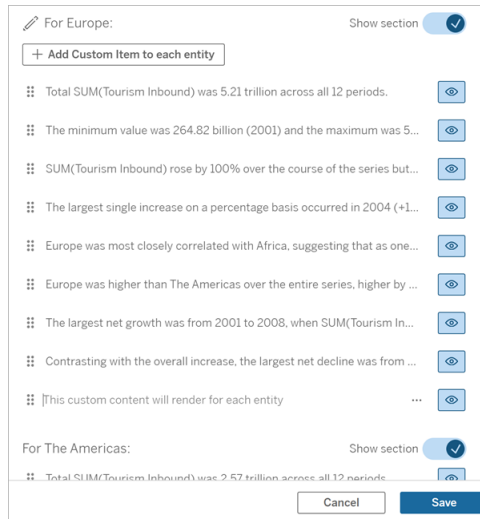

Note: Copied bullets can only be added to the section that the original bullet is in.

Add custom content in drilldown sections

For stories that have two dimensions, each section after the first section is called a drilldown section. Drilldown sections focus on an individual primary dimension entity (i.e. The Americas in the following example).

Because the drilldown sections have the same content structure, custom content added in the first section (i.e., Europe) are applied to each additional section (i.e., The Americas). You can only create or edit content in the first drilldown section.

1. In your Data Story, click **Edit** to open the Edit dialog box.
2. In the first drilldown section, click **Add Custom Item** to each entity.
3. Enter your custom content.
4. Click **Save**.

Custom content in drilldown sections already has a context variable called **Current Category** value (dynamic). This creates a dimension value option called **Current Category** value (dynamic) which always represents the section that the drilldown section is about.

Tip: To create content that only appears in a single specific drilldown section, you can use conditional logic to ensure it only writes where appropriate.

Customize Your Tableau Data Story: Context Variables

Context variables are functions that can be referenced by other functions. In other words, you can use context variables to nest functions within other functions.

After you define your context variable, it appears as a function that you can use when adding new functions to your Tableau Data Story.

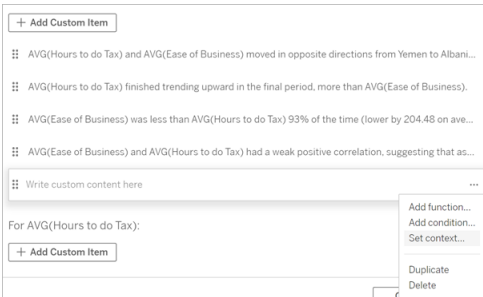

Note: You can have multiple context variables set for each custom sentence, but you must define each context variable separately for each piece of custom content.

Set a context variable

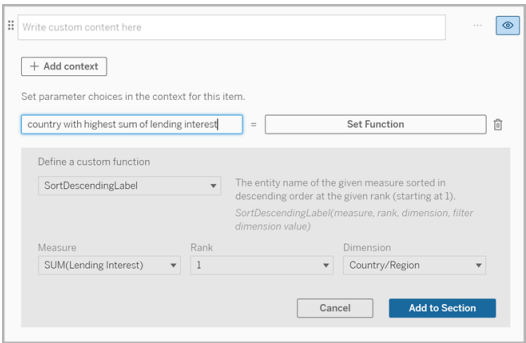

1. In your **Data Story**, click **Edit** to open the Edit dialog box.
2. Click **Add Custom Item**.

Tableau Server on Windows Help

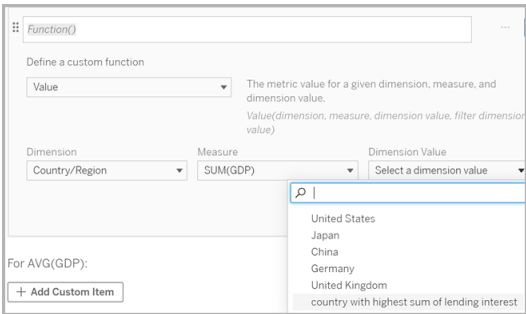

3. Click the menu in the right side of your custom content box and select **Set context**.

4. Click **Add context**.
5. Name the context variable and click **Set Function**.
6. Define your custom function and choose a dimension.

7. Click **Add to Section**.
8. Click back into the sentence where you set your context variable.
9. Follow the steps to Add functions.

Now, your context variable is listed as an option in the **Dimension Value** drop-down list when adding your function.

When to use a context variable: reference two or more measures

Let's say that you want to refer to two or more measures in one analytical sentence in your **Data Story**. Without a context variable, we can write a sentence for only one measure at a time. But if we use a context variable, we can reference more than one measure in one sentence.

To reference two or more measures with a context variable, your **Data Story** must have:

- 1 dimension
 - 2 or more measures
1. In your **Data Story**, click **Edit** to open the Edit dialog box.
 2. Click **Add Custom Item**.
 3. Click the menu in the right side of your custom content box and select **Set context**.
 4. Click **Add context**.
 5. Name the context variable and click **Set Function**.
 6. Define your custom function and choose a dimension.
 7. Click **Add to Section**.

Set parameter choices in the context for this item.

Country with the highest GDP = Set Function

Define a custom function

SortDescendingLabel The entity name of the given measure sorted in descending order at the given rank (starting at 1).
SortDescendingLabel(measure, rank, dimension, filter dimension value)

Measure: SUM(GDP) Rank: 1 Dimension: Country/Region

Cancel Add to Section

8. Click back into the sentence where you set your context variable.
9. Add your first function and fill in the required fields. In this example, we selected **DimensionValueLabel**, and then chose Country/Region from **Dimension**, and then country with the highest GDP (our context variable) from **Dimension Value**.

Tableau Server on Windows Help

Function()

Define a custom function

DimensionValueLabel: Country/Region

The label for a dimension value. Most useful in combination with "Current (dynamic)."

DimensionValueLabel(dimension, dimension value)

Dimension: Country/Region

Dimension Value: Country with the highest GDP

Cancel Add to Section

10. Click **Add to Section**.

11. Add your second function and fill in the required fields. In this example, we selected **Value**, and then chose Country/Region from **Dimension**, SUM(Lending Interest) from **Measure**, and country with the highest GDP (our context variable) from **Dimension Value**.

Function(): DimensionValueLabel(Country/Region, Country with highest GDP), which has the highest AVG (GDP, has a SUM of Functions)

Define a custom function

Value

The metric value for a given dimension, measure, and dimension value.

Value(dimension, measure, dimension value, filter dimension value)

Dimension: Country/Region

Measure: SUM(Lending Interest)

Dimension Value: Country with highest GDP

Cancel Add to Section

12. Click **Add to Section**.

13. Click **Save**.

Your **Data Story** writes a sentence that gives us insight into a secondary measure (Lending Interest) for the country that we're interested in (the country with the highest GDP).

For AVG(GDP):

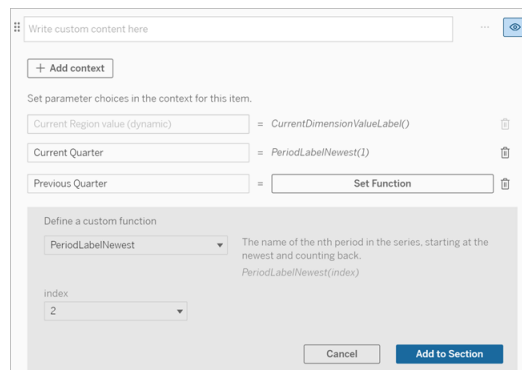

- Total AVG(GDP) is **348.03 trillion** across all **five** entities.
- The AVG(GDP) of **348.03 trillion** was driven by United States with **173 trillion**, Japan with **62.36 trillion** and China with **46.99 trillion**.
- The minimum value is **28.48 trillion** (United Kingdom) and the maximum is **173 trillion** (United States), a difference of **144.52 trillion**, averaging **69.61 trillion**.
- United States (**173 trillion**) is more than **two** times bigger than the average across the **five** entities.
- United States, which has the highest AVG (GDP), has a Lending Interest SUM of 0.7 billion.

When to use a context variable: period-over-period analysis

A context variable is helpful when you want to analyze performance over two different periods in your **Data Story**. You can create a custom sentence that writes about a measure displayed in your drilldown section and compares the measure against different periods, such as year over year or month over month.

To set up a period-over-period analysis, your Data Story must have:

- 2 dimensions: 1 time period dimension (primary) and 1 non-time period dimension (secondary)
 - 1–3 measures
1. Create your **Data Story**.
 2. In the Fields dialog box, make sure your time period dimension is ordered first and click **Next**.
 3. In the Story dialog box, select **Continuous** and click **Done**.
 4. Open the Edit dialog box, and select **Add Custom Item** in the first drilldown area.
 5. Create two context variables that represent your time periods. For example, "Current Quarter" and "Previous Quarter."

6. Create an *increased* sentence by adding custom language and functions. The content of this sentence results in "[CurrentDimensionValueLabel] increased [X%] over the quarter."
7. Type in the function followed by the word "increased" in the custom text box.
8. Add the function that returns the percent change of your measurement during your time period.

CurrentDimensionValueLabel() increased Function()

Define a custom function

PercentDifference

The percent difference in measure values between the two provided dimension values.
PercentDifference(dimension, measure, first dimension value, second dimension value, filter dimension value)

Dimension: QUARTER(Order Date) Measure: total orders First Dimension Value: Previous Quarter

Second Dimension Value: Current Quarter Filter Dimension Value (Optional): Current Region value (dynamic)

Cancel Add to Section

9. Click **Add to Section**.
10. Duplicate custom content and create a *decreased* version by replacing the word "increased" with "decreased." The functions stay the same.

West was higher than Central over the entire series, higher by 220 on average. West was higher than ...

CurrentDimensionValueLabel() increased PercentDifference(QUARTER(Order Date), total orders, Previous Quarter, Current Quarter, Current Region value (dynamic)) over the quarter

For East:

Total total orders was 2,848 across all four quarters.

The minimum value was 362 (Q1) and the maximum was 1,022 (Q4), averaging 712.

Duplicate
Delete

11. Add conditions for each sentence so that only one is written, depending on the data.

CurrentDimensionValueLabel() increased PercentDifference(QUARTER(Order Date), total orders, Previous Quarter, Current Quarter, Current Region value (dynamic)) over the quarter

+ Add condition

Write this custom content when the following condition is met:

Value(QUARTER(Order Date), total orde...) > Value(QUARTER(Order Date), total orde...)

Cancel Add to Section

12. For the *increased* sentence, set conditions in line with the following example:

Left Argument = Value function

Dimension = Quarter(OrderDate). Select your time period dimension

Measure = SUM(Total Orders). Select the measure you used for the calculation

Dimension Value = Current Quarter. One of the context variables

Filter Dimension Value = Current Region value (dynamic). This is the preset context variable

Middle Argument = > (greater than)

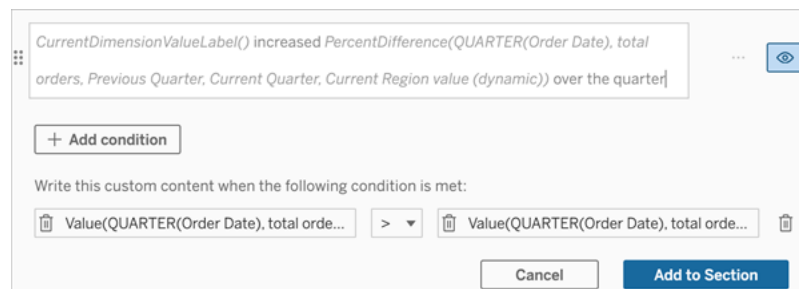

Right Argument = Value function

Dimension= Quarter(OrderDate). Select your time period dimension

Measure = Total(Total Orders). Select the measure you used for the calculation

Dimension Value = Previous Quarter. One of the context variables

Filter Dimension Value = Current Region value (dynamic). This is the preset context variable

13. For the *decreased* sentence, set the same conditions, but replace the > (greater than) sign with the < (less than) sign. The right and left arguments remain the same.
14. Click **Save**, and your **Data Story** writes a sentence that includes the insights from analyzing the two time periods.

Customize Your Tableau Data Story: Functions

If you'd like to customize your Tableau Data Story with a function, it helps to know what functions you can use, what each function does, and what dimensions and measures you'll need for each function.

Learn how to Add functions to your Data Story.

Click a letter to see functions that begin with that letter. If no functions start with that letter, the functions that start with the next letter in the alphabet are shown. You can also press Ctrl+F (Command-F on a Mac) to open a search box that you can use to search the page for a specific function.

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

Average

Description: The average value of the given measure.

Syntax: Average(dimension, measure, filterDimensionValue)

Count

Description: The number of dimension values within a given dimension.

Syntax: Count(dimension)

Difference

Description: The difference in measure values between the two provided dimension values.

Syntax: Difference(dimension, measure, firstDimensionValue, secondDimensionValue, filterDimensionValue)

DifferenceFromMean

Description: The difference between the mean and the measure value for the given dimension value.

Syntax: `DifferenceFromMean(dimension, measure, firstDimensionValue, filterDimensionValue)`

Direction

Description: Language describing the direction (e.g., increase or decrease) between measure values for the two provided dimension values.

Syntax: `Direction(dimension, measure, firstDimensionValue, secondDimensionValue, filterDimensionValue, phrase)`

Ending Label

Description: The name of the last period in the series.

Syntax: `Label(measure)`

EndingValue

Description: The value at the last period in the series for the given measure.

Syntax: `EndingValue(measure, filterDimensionValue)`

Label

Description: The label for the given measure.

Syntax: `Label(measure)`

LargestNegativeChangeDifference

Description: The value of the largest negative period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestNegativeChangeDifference(measure, filterDimensionValue)

LargestNegativeChangeEndingLabel

Description: The name of the ending period for the largest negative period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestNegativeChangeEndingLabel(measure, filterDimensionValue)

LargestNegativeChangeEndingValue

Description: The ending value of the largest negative period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestNegativeChangeEndingValue(measure, filterDimensionValue)

LargestNegativeChangePercentDifference

Description: The percent change of the largest negative period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestNegativeChangePercentDifference(measure, filterDimensionValue)

LargestNegativeChangeStartingLabel

Description: The name of the starting period for the largest negative period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestNegativeChangeStartingLabel(measure, filterDimensionValue)

LargestNegativeChangeStartingValue

Description: The starting value of the largest negative period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestNegativeChangeStartingValue(measure, filterDimensionValue)

LargestNegativePercentChangeDifference

Description: The value of the largest negative period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestNegativePercentChangeDifference(measure, filterDimensionValue)

LargestNegativePercentChangeEndingLabel

Description: The name of the ending period for the largest negative period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestNegativePercentChangeEndingLabel(measure, filterDimensionValue)

LargestNegativePercentChangeEndingValue

Description: The ending value of the largest negative period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestNegativePercentChangeEndingValue(measure, filterDimensionValue)

LargestNegativePercentChangePercentDifference

Description: The percent change of the largest negative period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestNegativePercentChangePercentDifference(measure, filterDimensionValue)

LargestNegativePercentChangeStartingLabel

Description: The name of the starting period for the largest negative period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestNegativePercentChangeStartingLabel(measure, filterDimensionValue)

LargestNegativePercentChangeStartingValue

Description: The starting value of the largest negative period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestNegativePercentChangeStartingValue(measure, filterDimensionValue)

LargestPositiveChangeDifference

Description: The value of the largest positive period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestPositiveChangeDifference(measure, filterDimensionValue)

LargestPositiveChangeEndingLabel

Description: The name of the ending period for the largest positive period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestPositiveChangeEndingLabel(measure, filterDimensionValue)

LargestPositiveChangeEndingValue

Description: The ending value of the largest positive period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestPositiveChangeEndingValue(measure, filterDimensionValue)

LargestPositiveChangePercentDifference

Description: The percent change of the largest positive period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestPositiveChangePercentDifference(measure, filterDimensionValue)

LargestPositiveChangeStartingLabel

Description: The name of the starting period for the largest positive period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestPositiveChangeStartingLabel(measure, filterDimensionValue)

LargestPositiveChangeStartingValue

Description: The starting value of the largest positive period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestPositiveChangeStartingValue(measure, filterDimensionValue)

LargestPositivePercentChangeDifference

Description: The value of the largest positive period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestPositivePercentChangeDifference(measure, filterDimensionValue)

LargestPositivePercentChangeEndingLabel

Description: The name of the ending period for the largest positive period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestPositivePercentChangeEndingLabel(measure, filterDimensionValue)

LargestPositivePercentChangeEndingValue

Description: The ending value of the largest positive period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestPositivePercentChangeEndingValue(measure, filterDimensionValue)

LargestPositivePercentChangePercentDifference

Description: The percent change of the largest positive period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestPositivePercentChangePercentDifference(measure, filterDimensionValue)

LargestPositivePercentChangeStartingLabel

Description: The name of the starting period for the largest positive period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestPositivePercentChangeStartingLabel(measure, filterDimensionValue)

LargestPositivePercentChangeStartingValue

Description: The starting value of the largest positive period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestPositivePercentChangeStartingValue(measure, filterDimensionValue)

LongestStreakDifference

Description: The difference over the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakDifference(measure, filterDimensionValue)

LongestStreakDirection

Description: The direction (positive or negative) of the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakDirection(measure, filterDimensionValue)

LongestStreakEndingLabel

Description: The name of the ending period for the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakEndingLabel(measure, filterDimensionValue)

LongestStreakEndingValue

Description: The ending value of the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakEndingValue(measure, filterDimensionValue)

LongestStreakLength

Description: The largest number of periods of consecutive increase or decrease for the given series.

Syntax: LongestStreakLength(measure, filterDimensionValue)

LongestStreakPercentDifference

Description: The percent difference over the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakPercentDifference(measure, filterDimensionValue)

LongestStreakStartingLabel

Description: The name of the starting period for the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakStartingLabel(measure, filterDimensionValue)

LongestStreakStartingValue

Description: The starting value of the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakStartingValue(measure, filterDimensionValue)

MaxLabel

Description: The name of the entity with the maximum value for the given measure.

Syntax: MaxLabel(dimension, measure, filterDimensionValue)

MaxValue

Description: The maximum value for the given measure.

Syntax: MaxValue(measure)

Median

Description: The median value for the given measure.

Syntax: Median(dimension, measure, filterDimensionValue)

MinLabel

Description: The name of the entity with the minimum value for the given measure. Syntax:

MinLabel(dimension, measure, filterDimensionValue)

MinValue

Description: The minimum value for the given measure.

Syntax: MinValue(dimension, measure, filterDimensionValue)

PercentDifference

Description: The percent difference in measure values between the two provided dimension values.

Syntax: PercentDifference(dimension, measure, firstDimensionValue, secondDimensionValue, filterDimensionValue)

PercentOfWhole

Description: The percent in measure values for a given dimension value over the total measure values for that dimension.

Syntax: PercentOfWhole(dimension, measure, dimensionvalue, filterDimensionValue)

PeriodLabel

Description: The name of the nth period in the series, starting at 1.

Syntax: PeriodLabel(index)

PeriodLabelNewest

Description: The name of the nth period in the series, starting at the newest and counting back.

Syntax: PeriodLabelNewest(index)

PeriodValue

Description: The value of the given measure at the nth period in the series, starting at 1.

Syntax: PeriodValue(measure, index, filterDimensionValue)

PeriodValueNewest

Description: The value of the given measure at the nth period in the series, starting at the newest and counting back.

Syntax: PeriodValueNewest(measure, index)

Range

Description: The difference between the maximum and minimum values for the given measure.

Syntax: Range(dimension, measure, filterDimensionValue)

SortAscendingLabel

Description: The entity name of the given measure sorted in descending order at the given rank (starting at 1).

Syntax: SortAscendingLabel(measure, rank, dimension, filterDimensionValue)

SortAscendingValue

Description: The value of the given measure sorted in ascending order at the given rank (starting at 1).

Syntax: SortAscendingValue(measure, rank, dimension, filterDimensionValue)

SortDescendingLabel

Description: The entity name of the given measure sorted in descending order at the given rank (starting at 1).

Syntax: SortDescendingLabel(measure, rank, dimension, filterDimensionValue)

SortDescendingValue

Description: The value of the given measure sorted in descending order at the given rank (starting at 1).

Syntax: SortDescendingValue(measure, rank, dimension, filterDimensionValue)

StartingLabel

Description: The name of the first period in the series.

Syntax: StartingLabel()

StartingValue

Description: The value at the first period in the series for the given measure.

Syntax: StartingValue(measure, filterDimensionValue)

StartToFinishDifference

Description: The difference between the values for the first and last periods in the given series.

Syntax: StartToFinishDifference(measure, filterDimensionValue)

StartToFinishPercentDifference

Description: The percent difference between the values for the first and last periods in the given series.

Syntax: StartToFinishPercentDifference(measure, filterDimensionValue)

StdDev

Description: The standard deviation value for the given measure.

Syntax: StdDev(dimension, measure, filterDimensionValue)

Sum

Description: The sum of measure values for the two provided dimension values.

Syntax: Sum(dimension, measure, firstDimensionValue, secondDimensionValue, filterDimensionValue)

Total

Description: The sum total value for the given measure.

Syntax: Total(dimension, measure, filterDimensionValue)

Value

Description: The metric value for a given dimension, measure, and dimension value.

Syntax: Value(dimension, measure, dimension value, filterDimensionValue)

Z-Score

Description: The z-score for the given measure.

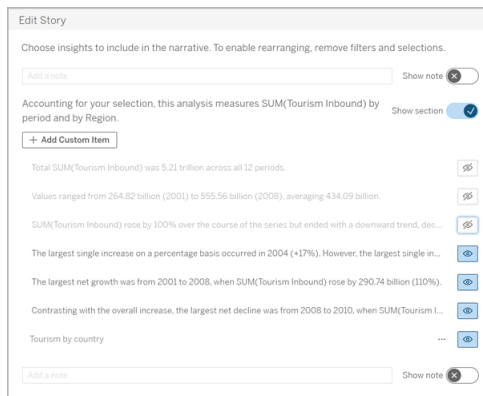

Syntax: Z-Score(dimension, measure, firstDimensionValue, filterDimensionValue)

Customize Your Tableau Data Story: Hide and Reorder Content

Customize your Tableau Data Story with the content that is most important to you and your audience by hiding or reordering content within your story.

Hide content and sections

1. Create your **Data Story** and click **Edit** to open the Edit dialog box.
2. Set sections to show or hide by clicking the **Show section** switch to the on or off position.
3. Hover over the blue box to the right of each individual sentence, and click the box to show or hide from view.
4. Click **Save**.

Now, only the sentences and sections that are set to **Show** appear in your Data Story.

Reorder content within a section

1. Create your **Data Story** and click **Edit** to open the Edit dialog box.
2. Hover over the left-side menu of the content you want to reorder. Your cursor turns into a hand icon.
3. Click the item with your cursor and drag it anywhere within the same section.
4. Click **Save**.

Now, the sentences appear in your **Data Story** in the order that you set them to.

Note: Currently, content can only be moved within the same section. Moving entire sections isn't yet supported.

Add More Data to Your Tableau Data Story

Data Stories currently supports stories with two dimensions and one measure, or one dimension and up to 10 measures. If you'd like to write about data that you don't need to show on your dashboard, then use a hidden sheet to simplify your dashboard. If you'd like to add more than two dimensions to your story, then concatenate dimensions or create multiple data stories and stack them.

Use a hidden sheet

If you have data that you want to include in a Tableau Data Story and don't need to show all the data that drove the insight, you can use a hidden sheet to bring additional measures and dimensions into your story without cluttering the dashboard.

1. Drag the **Data Story** object to your dashboard to see which worksheets you can write about in the Data Story dialog box. In this example, there are two worksheets available

to write about.

Configure

Views

Fields

Story

Choose a worksheet to write about.

☐

 Tourism Over Time

☒

 Tourism by Country/Region

To write stories, Tableau processes summary data in the Tableau Cloud or Tableau Server instance you are logged in to. By clicking Next, you acknowledge that Tableau sends data in accordance with the foregoing.

[Learn More](#)

Next

2. Bring in another data source, such as "Population," by navigating to the left-hand menu, selecting **Floating**, and dragging that sheet onto your dashboard.

Configure

Views

Fields

Story

Choose a worksheet to write about.

☐

 Population

☐

 Tourism By Country/Region

☐

 Tourism Over Time

Next

The Data Story dialog box updates with the new available data source.

3. Click into **Layout** and adjust the size to 1 x 1 to hide the sheet but keep the underlying data in your story.

You can now configure your stories using this hidden sheet.

Note: You may need to deselect additional legend elements to keep the sheet hidden.

Concatenate dimensions

If your data contains three dimensions and one measure and is a **Discrete Story**, you can concatenate (link together) two of those dimensions by creating a calculated field.

1. From the worksheet you want to use in your story, click **Analysis** and select **Create Calculated Field**.
2. Name the calculated field and use the following formula to create your calculation, using the + sign to join the dimensions.
[Dimension 1] + [Dimension 2]

Tip: Drag your dimensions into the **Calculated Field** box and place them in the formula.

3. Click **OK**.
4. Drag your new calculated field into the **Detail** pane to make it accessible in your data story.

Stack multiple data stories

Write about more measures and dimensions by creating multiple **Data Stories** and stacking them vertically or horizontally on your dashboard.

For example, if you wanted to create a story about actual revenue vs benchmark revenue, you could create two different stories—one with the actual revenue and the first benchmark, and another with the actual revenue and the second benchmark—and compare them.

Add a Pop-Up Tableau Data Story to Your Dashboard

You can place a Tableau Data Story in a pop-up window that allows your users to open a story, read it, and then close it when they're done. This is a great way to save space being used by already-established dashboards or to reduce the amount of clutter and information on a dashboard.

1. Add a Tableau Data Story to a Dashboard.
2. Set the container to **Floating** by clicking the menu and selecting **Floating**.

Tip: Another way to set the container to **Floating** is by holding the shift key while dragging the container onto your dashboard.

3. Navigate to the **Layout** tab in the left-hand column and set the background color to white.

- Click the menu that is associated with your floating container to show its settings, and select **Add Show/Hide Button**. This creates an "X" icon that allows you to show or hide your story.

Note: If your story is selected, then your button is partially obscured by the sidebar options that are part of the Data Story object. Click anywhere outside of the story to reveal the button.

- Hover over the "X" icon to show instructions for opening or closing the story. In this example, you're being prompted to press the Alt key at the same time you click the "X" icon.

- Collapse the story by clicking the "X" icon at the same time as pressing the key indicated in your prompt.

The story collapses, but the menu remains on the dashboard so that the user can expand the story when needed. You can move your collapsible, floating story around your dashboard as desired.

Create Custom Measure Relationships in Your Tableau Data Story

You can create a relationship story in your Tableau Data Story to see how data compares to another set of data. To build a relationship story, you must have at least two measures and one dimension. Data that you'd like to compare is often grouped into one column of data named something such as "Year" or "Month," with values such as "2022" or "March."

You can [Create a Simple Calculated Field](#) to separate "2022" from "2021" (or March from February), so that you can compare the two time periods in a relationship story.

1. Start in the sheet that you want to use in your **Data Story**.
2. Click **Analysis**, and select **Create a Calculated Field**.
3. Create a calculated field such as "Current Period."

Tip: Follow the structure of the calculated field shown here, but substitute your own dimension or measure names (orange text).

4. Create a calculated field such as "Previous Period."

5. Drag the new measures onto the **Detail** mark.
6. From your dashboard, click the story and add the two new measures into your **Data Story**.

The screenshot shows the 'Configure' dialog box in Tableau, with the 'Fields' tab selected. The dialog has three tabs: 'Views', 'Fields', and 'Story'. Below the tabs, there is a header 'Configure' and a sub-header 'Fields'. The main area contains the instruction 'Drag and drop fields to include in your story.' followed by three sections: 'Dimensions' with a single field 'YEAR(Year) 1', 'Measures' with two fields 'SUM(Current Period) 1' and 'SUM(Previous Period) 2', and 'Ignored' which is empty. At the bottom, there are 'Back' and 'Next' buttons.

Configure

Views Fields Story

Drag and drop fields to include in your story.

10. Click **Save**.

Your story now writes sentences that compare the custom measures.

Refresh Parameters in a Tableau Data Story

If you've added a parameter to your dashboard and are using Data Stories, you'll notice that clicking the parameter refreshes your visualization, but not the story. This happens because the parameter doesn't refresh the underlying data like a filter does.

To refresh your Tableau Data Story with the parameter data, add a "refresh" button to your dashboard that updates your story to align with your parameter.

1. Create a new sheet in your workbook.
2. Create a **Calculated Field** in the new sheet with the following info:

Name: Refresh

Contents: "refresh"

3. Click **OK**, and then drag the new calculated field (Refresh) onto your new sheet.
4. Right-click the field and click **Show Header** to hide the header.

5. Choose a shape for your button.

6. Return to your dashboard and drag the sheet containing the refresh button onto your dashboard next to the parameter.
7. Hover over the button, select **More Options**, and click **Title** to hide the title.
8. Hover over the button and click **Use as Filter**.

9. Adjust your parameter and then click on the new refresh button. The button updates your story to align with the parameter.

Use a Table Calculation in a Tableau Data Story

You can use a **Table Calculation** as a measure in a Tableau Data Story in addition to the measure that you used to create the table calculation.

1. From the **Marks** card, click the right side of your field to open a menu, and click **Quick Table Calculation**.

Tableau Server on Windows Help

2. After you create your table calculation, drag it to **Measures** in the **Data** pane and rename it.

3. Drag your original measure (e.g., Sales) back to the **Rows** shelf, and then drag your new calculation (e.g., Sum of Sales) into the **Tooltip**. Your visualization may remain the same, but you now have access to the new measure.

4. Go to your dashboard and drag the **Data Story** object onto the dashboard. Both measures appear when creating your story.

Discover Insights Faster with Explain Data

Explain Data in the Data Guide helps you to inspect, uncover, and dig deeper into the marks in a viz as you explore your data. You can use Explain Data to analyze dashboards, sheets, or selected marks for possible outliers and correlations in the underlying data. Explain Data builds statistical models and proposes possible explanations for individual marks in a viz, including potentially related data from the data source that isn't used in the current view.

For information on running Explain Data and exploring explanations, see [Get Started with Explain Data](#).

Note: This topic describes how Explain Data works in Tableau 2021.2 and later versions. If you have a previous version of Tableau, read this topic in [version 2021.1 of Explain Data help](#).

As you build different views, use Explain Data as a jumping-off point to help you explore your data more deeply and ask better questions. For more information, see [How Explain Data helps to augment your analysis](#). For information on what characteristics make a data source more interesting for use with Explain Data, see [Requirements and Considerations for Using Explain Data](#).

Access to Explain Data

Explain Data is enabled by default at the site level. Server administrators (Tableau Server) and site administrators (Tableau Cloud) can control whether Explain Data is available for a site. For more information, see [Disable or Enable Explain Data for a Site](#).

Authors who can edit workbooks and have the Run Explain Data permission capability for a workbook can run Explain Data in editing mode. All users with the Run Explain Data capability can run Explain Data in viewing mode in Tableau Cloud and Tableau Server.

When allowed by site administrators, explanations can be shared in viewing mode via email or Slack with other Tableau Cloud and Tableau Server users. For more information, see [Configure Tableau to allow users to share explanations via email and Slack](#).

Authors can use Explain Data Settings to control which explanation types are displayed in the Data Guide pane.

For information on controlling access to Explain Data, explanation types, and fields, see [Control Access to Explain Data](#).

How Explain Data helps to augment your analysis

Explain Data is a tool that uncovers and describes relationships in your data. It can't tell you what is causing the relationships or how to interpret the data. **You are the expert on your data.** Your domain knowledge and intuition are key in helping you decide what characteristics might be interesting to explore further using different views. For related information, see [How Explain Data Works and Requirements and Considerations for Using Explain Data](#).

For more information on how Explain Data works and how to use Explain Data to augment your analysis, see these Tableau Conference presentations:

- [From Analyst to Statistician: Explain Data in Practice \(1 hour\)](#)
- [Leveraging Explain Data \(45 minutes\)](#)

Get Started with Explain Data

Use Explain Data in your flow of analysis as you are exploring the marks in a viz. Explain Data runs automatically when the Data Guide pane is open and updates based on the current selection (dashboard, sheet, or mark).

Use Explain Data

- Run Explain Data on a dashboard, sheet, or mark
- Drill into explanations
- View analyzed fields
- Terms and concepts in explanations
- [Explanation Types](#)

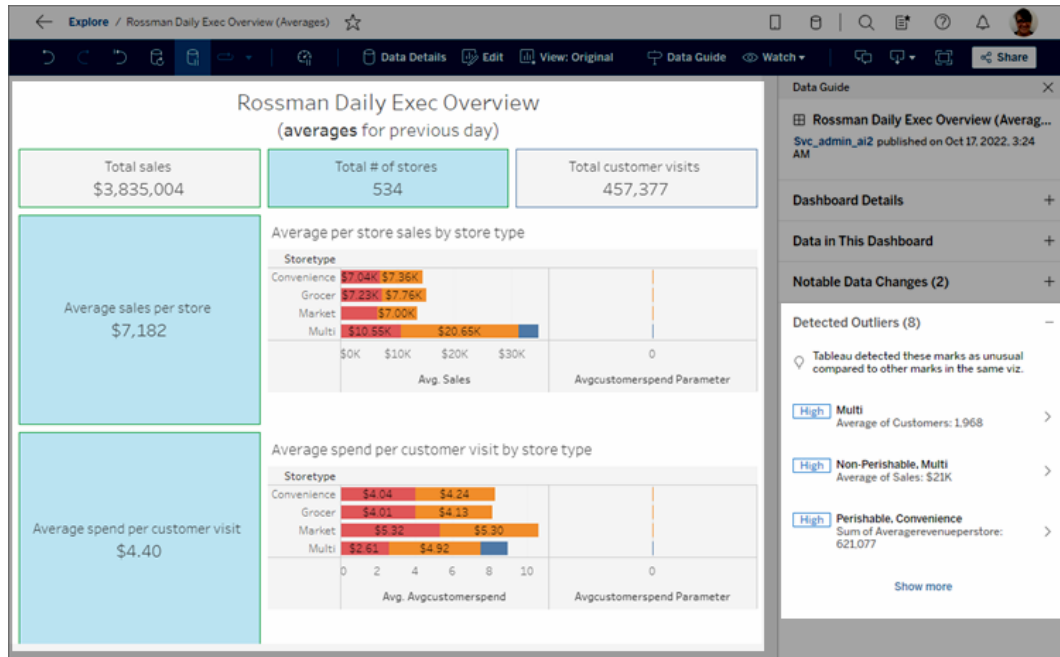

Author Workbooks and Control Access

- [Requirements and Considerations for Using Explain Data](#)
- [Change Explain Data Settings \(Authors-only\)](#)
- Control Access to Explain Data
- Disable or Enable Explain Data for a Site
- How Explain Data Works

Run Explain Data on a dashboard, sheet, or mark

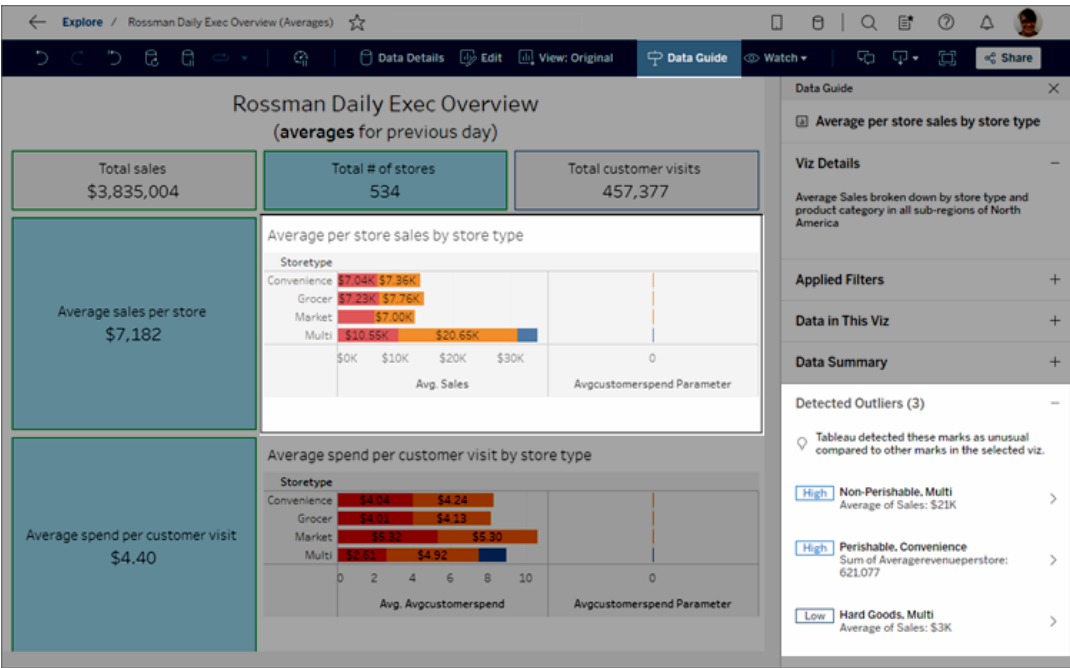

These are the basic steps to run Explain Data in Tableau Desktop, Tableau Cloud, and Tableau Server:

1. Open a dashboard or sheet in a workbook.
2. In the view toolbar, select **Data Guide**  to open the Data Guide pane.
3. If you open a dashboard, Explain Data will analyze it for outliers.

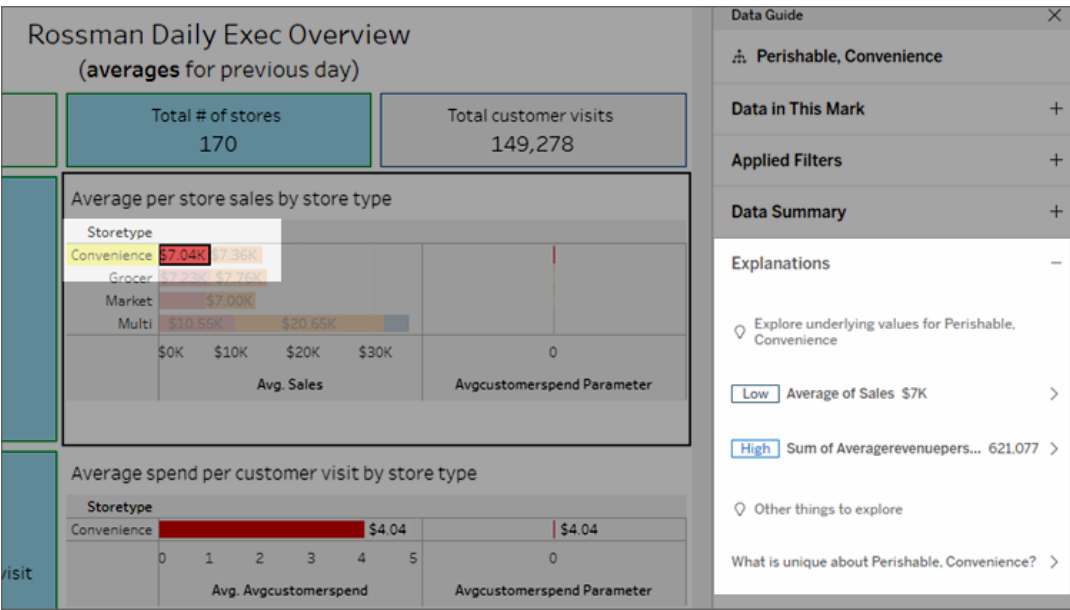

If you select a sheet in the dashboard, Explain Data analyzes the marks in that sheet for outliers.

Tableau Server on Windows Help

If you select a mark in the dashboard, Explain Data specifically analyzes that mark for explanations.

The marks that are being explained are highlighted in the viz as you select

corresponding explanations.

Optionally, you can select a mark in a viz, hover the cursor over the mark. In the tooltip menu, select **Data Guide**.

In Tableau Public, select the lightbulb in the tooltip menu to run Explain Data.

Possible explanations for the value of the analyzed mark are displayed in the Data Guide pane. Select different explanation names to expand the details and start exploring.

Explain Data permissions required for seeing explanations

If you see Detected Outliers with a note to contact the owner of the viz, it is because you need permission to see these types of explanations. Select the owner name to go to their Tableau content page with their email address. Contact the owner to ask them to give you Explain Data permissions for the workbook or view.

If you are the owner of the workbook, for more information on setting permissions, see [Control who can use Explain Data and what they can see](#).

Tips for using Explain Data

- Multiple marks can't be selected for comparison with each other.
- The view must contain marks that are aggregated using SUM, AVG, COUNT, COUNTD, or AGG (a calculated field).
- When Explain Data cannot analyze the type of mark selected, a message is displayed to indicate why. For more information, see [Situations where Explain Data is not available](#).
- The data you analyze must be drawn from a single, primary data source. Explain Data does not work with blended or cube data sources.
- For information on what characteristics make a data source more interesting for use with Explain Data, see Requirements and Considerations for Using Explain Data.

Drill into explanations

1. In the Data Guide pane, select an explanation name to see more details.

Select an explanation to expand or contract its details.

2. Scroll to see more explanation details.
3. Hover over charts in the explanations to see details on different data points. Select the **Open**  icon to see a larger version of the visualization.

Creators or Explorers who open the view for editing can select the **Open**  icon to open the visualization as a new worksheet and explore the data further.

Note: Creators and Explorers who have editing permissions can also control Explain Data Settings. For more information, see [Control Access to Explain Data](#).

4. Hover over a Help icon  to see tooltip help for an explanation. Select the Help icon  to keep the tooltip open. Select a **Learn More** link to open the related help topic.

View analyzed fields

1. Run Explain Data on a dashboard, sheet, or mark.

2. In the Data Guide pane, under **Explore underlying values for**, select a target measure name.

3. Select the *number-of-fields* link at the bottom of the pane.

Authors have the option to open Explain Data Settings to control which fields are included in the analysis. For more information, see [Change fields used for statistical analysis](#).

Terms and concepts in explanations

The following terms and concepts appear frequently in explanations. You may find it helpful to become acquainted with their meaning in the context of using Explain Data.

What is a mark?

A mark is a selectable data point that summarizes some underlying record values in your data. A mark can be made of a single record or multiple records aggregated together. Marks in

Tableau can be displayed in many different ways such as lines, shapes, bars, and cell text.

Tableau gets the records that make up the mark based on the intersection of the fields in the view.

The **analyzed mark** refers to a mark in a dashboard or sheet that was analyzed by Explain Data.

For more information on marks, see [Marks](#).

What does expected mean?

The expected value for a mark is the median value in the expected range of values in the underlying data in your viz. The expected range is the range of values between the 15th and 85th percentile that the statistical model predicts for the analyzed mark. Tableau determines the expected range each time it runs a statistical analysis on a selected mark.

If an expected value summary says the mark is *lower than expected* or *higher than expected*, it means the aggregated mark value is outside the range of values that a statistical model is predicting for the mark. If an expected value summary says the mark is *slightly lower* or *slightly higher* than expected or *within the range of natural variation*, it means the aggregated mark value is within the range of predicted mark values, but is lower or higher than the median.

For more information, see [What is an expected range?](#)

What are dimensions and measures?

Each column name in a database is a field. For example, Product Name and Sales are each fields. In Tableau, fields like Product Name that categorize data are called dimensions; fields with quantifiable data like Sales are called measures. Tableau aggregates measures by default when you drag them into a view.

Some explanations describe how the underlying record values and the aggregations of those values may be contributing to the value of the analyzed mark. Other explanations may mention the distribution of values across a dimension for the analyzed mark.

When you run Explain Data on mark, the analysis considers dimensions and measures in the data source that aren't represented in the view. These fields are referred to as unvisualized dimensions and unvisualized measures.

For more information on dimensions and measures, see [Dimensions and Measures](#).

What is an aggregate or aggregation?

An aggregate is a value that is a summary or total. Tableau automatically applies aggregations such as SUM or AVG whenever you drag a measure onto Rows, Columns, a Marks card option, or the view. For example, measures are displayed as SUM(Sales) or AVG(Sales) to indicate how the measure is being aggregated.

To use Explain Data, your visualization must use a measure that is aggregated with SUM, AVG, COUNT, COUNTD, or AGG.

For more information about aggregation, see [Data Aggregation in Tableau](#).

What is a record value?

A record is a row in a database table. A row contains values that correspond to each field. In this example, Category, Product Name, and Sales are fields (or columns). Furniture, Floor Lamp, and \$96 are the values.

Category	Product Name	Sales
Furniture	Floor Lamp	\$96.00

What is a distribution?

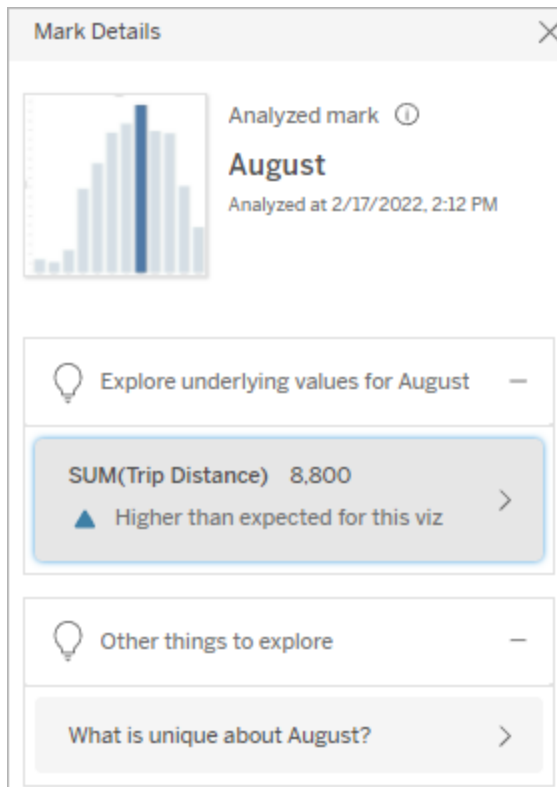

A distribution is a list of all the possible values (or intervals) of the data. It also indicates how often each value occurs (frequency of occurrence).

Explanation Types in Explain Data

Each time you select a new mark in a viz or dashboard and run Explain Data, Tableau runs a new statistical analysis considering that mark and the underlying data in the workbook. Possible explanations are displayed in expandable sections for the Data Guide pane. For information about how Explain Data analyzes and evaluates explanations, see [How Explain Data Works](#).

Explore underlying values

This section lists explanations for each measure that can be explained (referred to as *target measures*). Each explanation listed here describes a relationship with the values of the target measure that are tested on the analyzed mark. Use your real-world, practical understanding of the data to determine if the relationships found by Explain Data are meaningful and worth exploring.

In this example, Trip Distance is the target measure

Underlying Characteristics

These explanations describe how underlying records of the marks in the view may be contributing to the aggregated value of the measure being explained. Mark attributes can include **Extreme Values**, **Null Values**, **Number of Records**, or the **Average Value** of the mark.

Note: For definitions of common terms used in explanations, see Terms and concepts in explanations.

Extreme Values

This explanation type indicates if one or more records have values that are significantly higher or lower than most records. If the explanation is supported by a model, it indicates the extreme

value is affecting the target measure of the analyzed mark.

When a mark has extreme values, it doesn't automatically mean it has outliers or that you should exclude those records from the view. That choice is up to you depending on your analysis. The explanation is simply pointing out an extreme value in the mark. For example, it could reveal a mistyped value in a record where a banana cost 10 dollars instead of 10 cents. Or, it could reveal that a particular sales person had a great quarter.

Note: This explanation must be enabled by the author to be visible in viewing mode for a published workbook. For more information, see [Control Access to Explain Data](#).

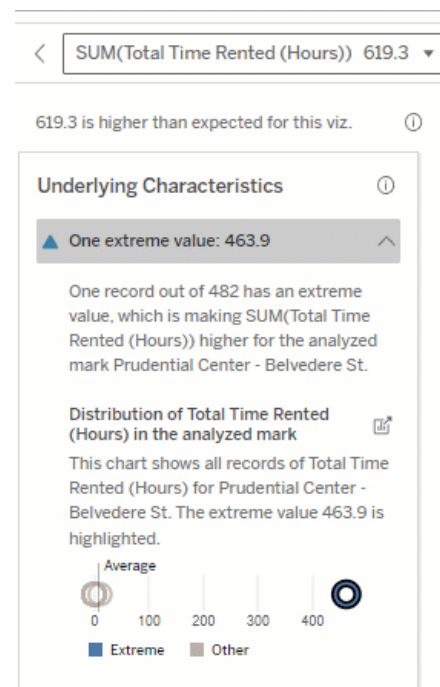

This explanation shows:

- The number of underlying records in the analyzed mark.
- The extreme value or values contributing to the value of the target measure.
- The distribution of values in the mark.
- The record details that correspond to each distribution value.

Exploration options:

- Hover over a circle in the chart to see its corresponding value.
- Select the left or right arrow below the details list to scroll through record details.
- If available, select **View Full Data**, and then select the **Full Data** tab to see all records in a table.
- Select the **Open** icon to see a larger version of the visualization.

Next steps for analysis:

In this example, a single extreme value of 463 hours rented is contributing to the higher than expected sum of Total Time Rented of 613 hours.

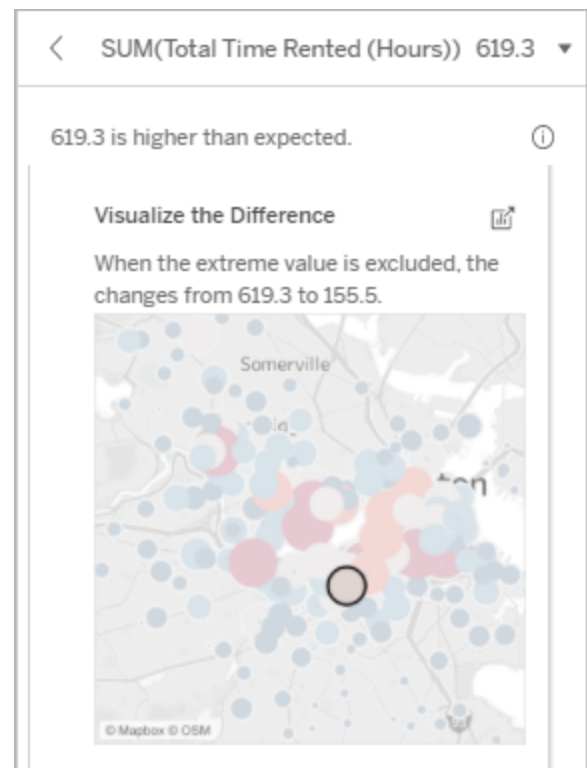

- If the number of records is low, examine these values compared to the extreme value.
- If the extreme value is significantly higher or lower than the other record values, exclude it and consider how it changes the value of the analyzed mark.
- When considering the data with and without the extreme value, use this as an opportunity to apply your practical knowledge about the data.

A likely reason for this high value could be that someone forgot to dock the bike when they returned it. In this case, the author might want to exclude this value for future analysis.

Visualize the Difference

This section shows:

- How the analyzed mark value changes when the extreme value is excluded.

Exploration options:

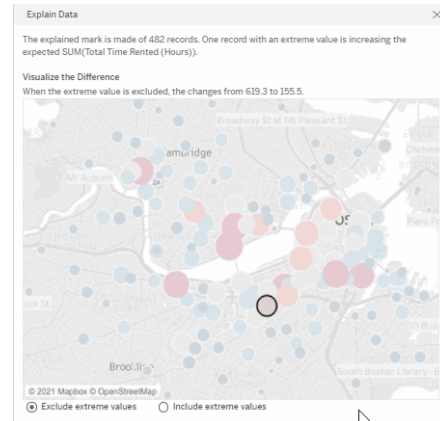

- Select the **Open**  icon to see a larger

version of the visualization.

- Explore the difference with and without the extreme value (or values).
- Authors can open the view as a new sheet and apply a filter to exclude the extreme value.

Next steps for analysis:

- If the extreme value is significantly higher or lower than the other record values, exclude it and see how it changes the value of the analyzed mark.
- When considering the data with and without the extreme value, use this as an opportunity to apply your practical knowledge about the data.

In this example, when the extreme value of 483 is excluded, the analyzed mark is no longer high compared to other marks in the view. Other marks now stand out. The author might want to explore the other marks to consider why these other locations have higher hours for bike rentals.

Null Values

The Null Values explanation type calls out situations where there is a higher than expected amount of missing data in a mark. It indicates the fraction of target measure values that are null and how the null values might be contributing to the aggregate value of that measure.

This explanation shows:

- The percent of values that are null in the target measure for the analyzed mark (blue circle).

Exploration options:

- Hover over each circle in the scatter plot to see its details.
- Scroll to see more of the chart.
- Select the **Open**  icon to see a larger version of the visualization.

In this example, the percent of null values in the target measure is shown as a blue circle.

Next steps for analysis:

- Optionally exclude null values in the mark for further analysis.

Number of Records

This explanation type describes when the count of the underlying records is correlated to the sum. The analysis found a relationship between the number of records that are being aggregated in a mark and the mark's actual value.

While this might seem obvious, this explanation type helps you explore whether the mark's value is being affected by the magnitude of the values in its records or simply because of the number of records in the analyzed mark.

This explanation shows:

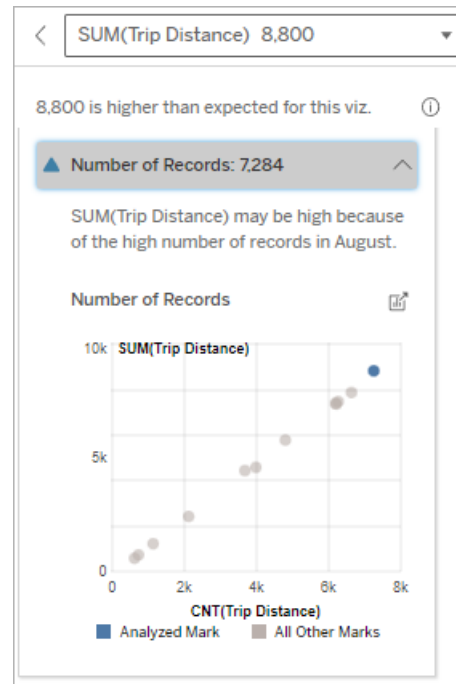

- The number of records in the target measure for the analyzed mark (dark blue bar).
- The number of records in the target measure for other marks in the source visualization (light blue bar).

Exploration options:

- Hover over each bar to see its details.
- Scroll to see more of the chart.
- Select the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- Compare whether the individual values of records are low or high, or the number of records in the analyzed mark is low or high.
- Authors, if you are surprised by a high number of records, you might need to normalize the data.

In this example, the number of records for Trip Distance is listed for each value of Ride Month, which is a dimension in the original visualization. August has the highest total trip distance value.

You might explore whether August has the highest value for trip distance because more rides occurred in August, or if it has the highest trip distance because some rides were longer.

Average Value of Mark

This explanation type describes when the average of a measure is correlated to the sum. Compare whether the average value is low or high, or the number of records is low or high.

This explanation shows:

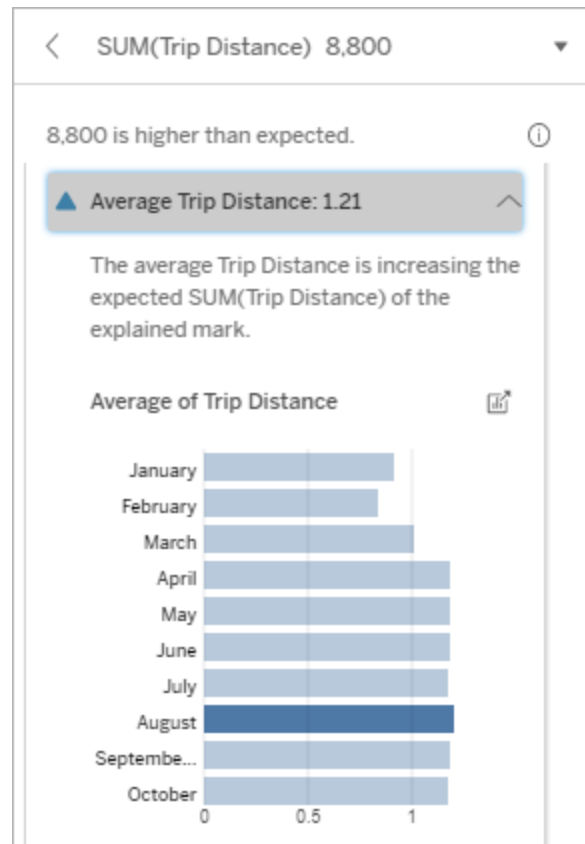

- The average of the target measure for each value of a dimension used in the source visualization.

Exploration options:

- Hover over each bar to see its details.
- Scroll to see more of the chart.
- Select the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- Compare whether the average value is low or high, or the number of records is low or high. For example, are profits high because you sold a lot of items or because you sold expensive items?
- Try to figure out why the analyzed mark has a significantly higher or lower average value.

In this example, the average trip distance for August is not significantly higher or lower than most months. This suggests that trip distance is higher for August because there were more rides in August, rather than from people taking longer rides.

Contributing Single Value

Use this explanation to understand the composition of the record values that make up the analyzed mark.

This explanation type identifies when a single value in an unvisualized dimension may be contributing to the aggregate value of the analyzed mark. An unvisualized dimension is a dimension that exists in the data source, but isn't currently being used in the view.

This explanation indicates when every underlying record of a dimension has the same value, or when a dimension value stands out because either many or few of the records have the same single value for the analyzed mark.

Note: For definitions of common terms used in explanations, see [Terms and concepts in explanations](#).

This explanation shows:

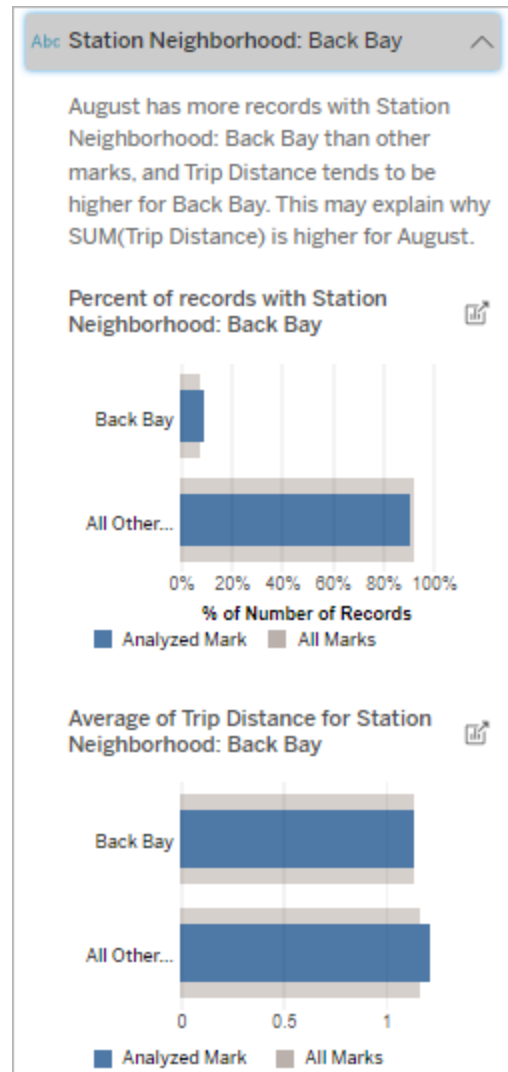

- The percent of the number of records for a single value of a dimension for the analyzed mark (blue bar) versus all marks (gray bar) in the source visualization.
- The percent of the number of records for all other values of a dimension for the analyzed mark (blue bar) versus all marks (gray bar) in the source visualization.
- The average of the target measure for the single value of a dimension in the analyzed mark (blue bar) versus all marks (gray bar).
- The average of the target measure for all other values of a dimension for the analyzed mark (blue bar) versus all marks (gray bar) in the source visualization.

Exploration options:

- Hover over each bar to see its details.
- Select the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- Use this explanation to understand the composition of the record values that make up the analyzed mark.
- Authors might want to create a new visualization to explore any unvisualized dimension surfaced in this explanation.

In this example, the statistical analysis has exposed that many of the rides come from the station neighborhood of Back Bay. Note that Station Neighborhood is an unvisualized dimension that has some relationship to Trip Distance in the underlying data for the source visualization.

Top Contributors

Use this explanation to see the values that make up the largest fraction of the analyzed mark.

For a COUNT aggregation, the top contributors show dimension values with the most records. For SUM, this explanation shows dimension values with the largest partial sum.

Contributing Dimensions

Use this explanation to understand the composition of the record values that make up the analyzed mark.

This explanation type shows that the distribution of an unvisualized dimension may be contributing to the aggregate value of the analyzed mark. This type of explanation is used for target measure sums, counts, and averages. An unvisualized dimension is a dimension that exists in the data source, but isn't currently being used in the view.

Note: For definitions of common terms used in explanations, see [Terms and concepts in explanations](#).

This explanation shows:

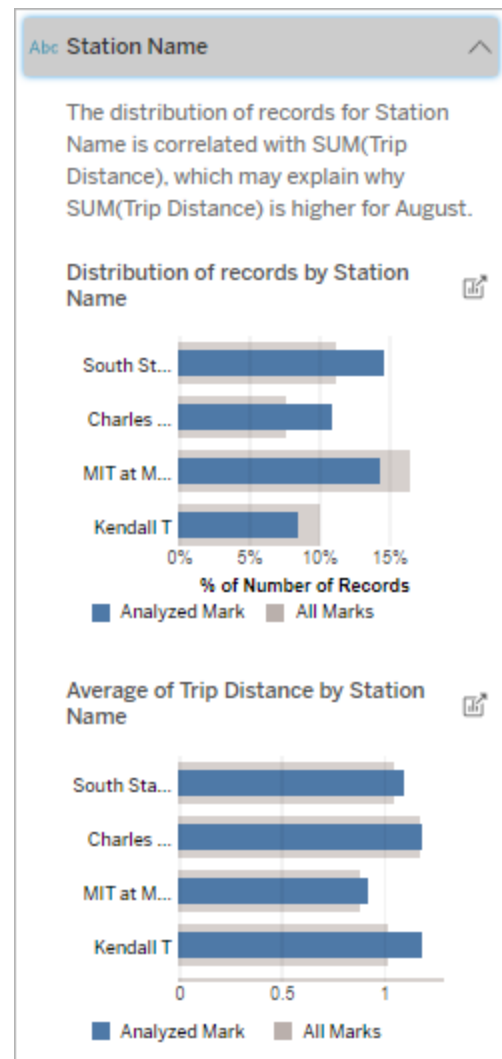

- The percent of the number of records for all values of a dimension for the analyzed mark (blue bar) versus all values of a dimension for all marks (gray bar) in the source visualization.
- The average of the target measure for all values of a dimension for the analyzed mark (blue bar) all values of a dimension for all marks (gray bar).

Exploration options:

- Hover over each bar to see its details.
- Scroll to see more of the chart.
- Select the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- Use this explanation to understand the composition of the record values that make up the analyzed mark.
- Authors might want to create a new visualization to explore any unvisualized dimensions surfaced in this explanation.

In this example, the statistical analysis has exposed that more rides were taken from South Station and MIT and fewer rides were taken from Charles Circle and Kendall, compared to rides taken for marks overall.

Note that Station Name is an unvisu-

alized dimension that has some relationship to Trip Distance in the underlying data for the source visualization.

Contributing Measures

This explanation type shows that the average of an unvisualized measure may be contributing to the aggregate value of the analyzed mark. An unvisualized measure is a measure that exists in the data source, but isn't currently being used in the view.

This explanation can reveal a linear or quadratic relationship between the unvisualized measure and the target measure.

Note: For definitions of common terms used in explanations, see [Terms and concepts in explanations](#).

This explanation shows:

- The relationship between the sum of the target measure and the average of an unvisualized measure for the analyzed mark (blue circle) and all marks (gray circles) in the view.
- If the sum of the target measure is high or low because the average value of the unvisualized measure is high or low.

Exploration options:

- Hover over each circle to see its details.
- Select the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- Authors might want to create a new visualization to explore any unvisualized measures surfaced in this explanation.

In this example, one possible reason why trip distance is high is because the average total time rented is also high.

Other things to explore

This section provides possible reasons why the analyzed mark is unique or unusual. These explanations:

- Do not explain why the value of this mark is what it is.
- Are not related in any way to the value of the measures in the source visualization.
- Do not take any target measures into account.

Other Dimensions of Interest

Use this explanation to understand the composition of the record values that make up the analyzed mark.

The distribution of an unvisualized dimension in the analyzed mark is unusual compared to the distribution of values for all other marks in the view. An unvisualized dimension is a dimension that exists in the data source, but isn't currently being used in the view.

Note: For definitions of common terms used in explanations, see Terms and concepts in explanations.

This explanation shows:

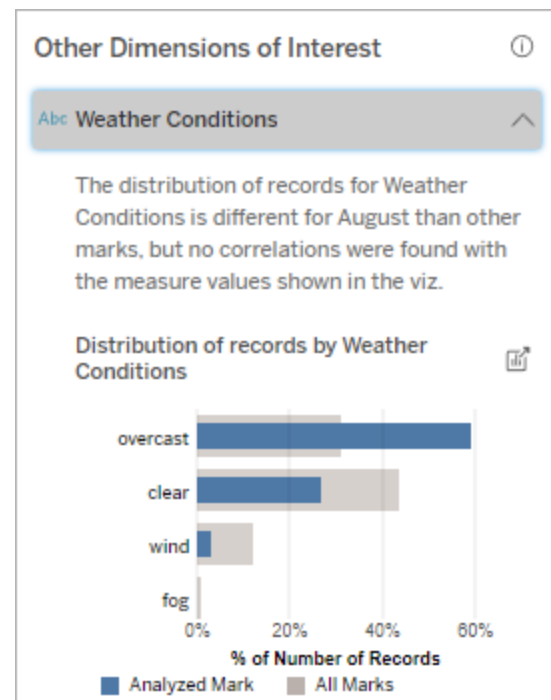

- The percent of the number of records for all values of a dimension for the analyzed mark (blue bar) versus all values of a dimension for all marks (gray bar) in the source visualization.

Exploration options:

- Hover over each bar to see its details.
- Scroll to see more of the chart.
- Select the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- Use this explanation to understand the composition of the record values that make up the analyzed mark.
- Authors might want to create a new visualization to explore any unvisualized dimensions surfaced in this explanation.

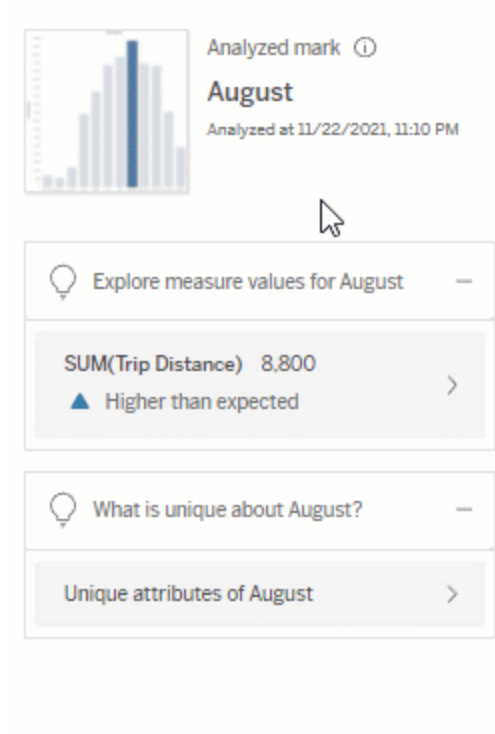

In this example, a high percentage of records are associated with overcast weather. Because the data is about bike rentals in Boston, and the analyzed mark is Trip Distance for

August, we can assume that the weather is typically warm and humid. People might have rented bikes more often on overcast days to avoid the heat. It's also possible there were more overcast days in August.

Analyzed Fields in Explain Data

Explain Data runs a statistical analysis on a dashboard or sheet to find marks that are outliers, or specifically on a mark you select. The analysis also considers possibly related data points from the data source that aren't represented in the current view.

Explain Data might not include every column from the data source in the analysis. In many cases, certain types of fields will be automatically excluded from the analysis. For more information, see [Fields excluded by default](#).

Note: Dimensions with more than 500 unique values won't be considered for analysis (unless allowed by the author in Explain Data Settings).

All users can view information on which fields are included or excluded in the current analysis. Creators and Explorers who have editing permissions can edit the fields used by Explain Data for statistical analysis.

View fields analyzed by Explain Data

When you expand an explanation for a measure that is contributing to the value of the mark, a link that indicates the number of fields considered in the analysis is displayed at the bottom of the Data Guide pane.

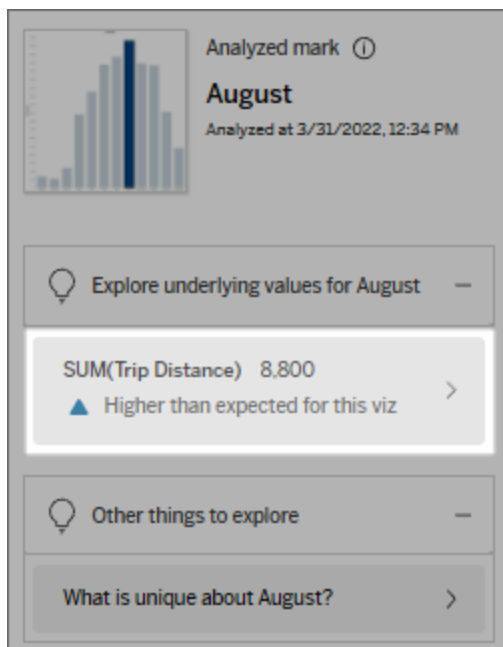

Click the link to see the list of fields included in or excluded from the current statistical analysis.

When a data source contains more than 1000 unvisualized dimensions or measures, you might see an alert asking if you want Explain Data to consider more fields. Click **Explain All** to run an analysis that includes more fields. The analysis may take longer to complete.

To view fields used by Explain Data for statistical analysis

1. [Run Explain Data on dashboard, sheet, or mark.](#)
2. In the Data Guide pane, under **Contributing to the value of**, click a measure name.

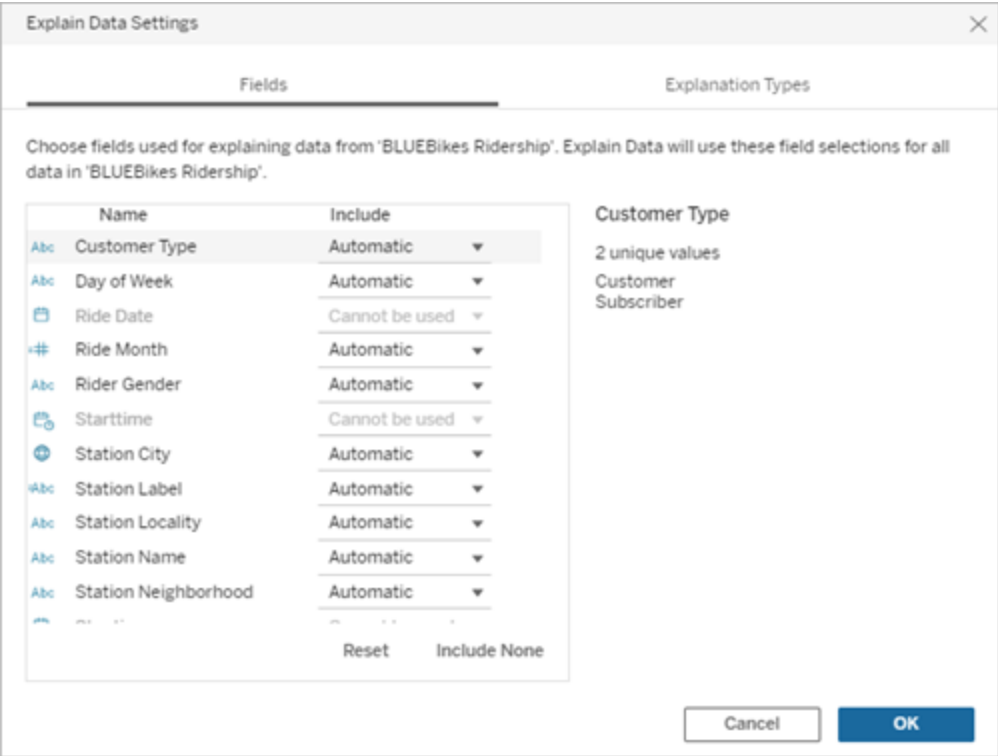

3. Click the *number-of-fields* link at the bottom of the pane.

Change fields used for statistical analysis

Creators and Explorers who have editing permissions can select fields to be included or excluded from the statistical analysis in the Fields tab of the Explain Data Settings dialog box.

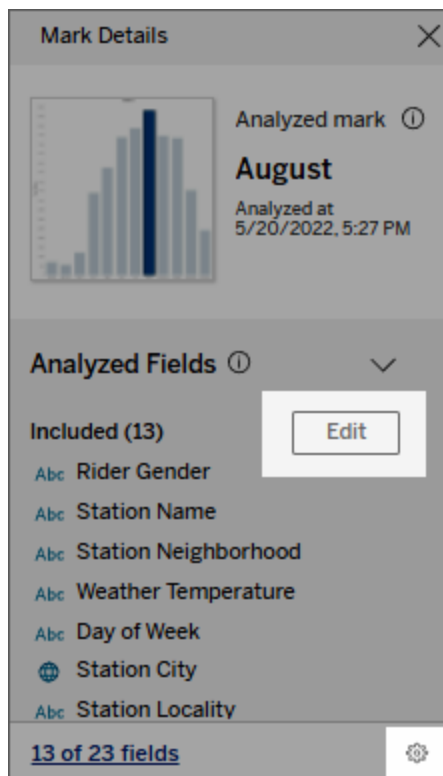

When a data source contains dimensions with a large number of unique values (up to 500), those fields won't be considered for analysis.

To edit the fields used by Explain Data for statistical analysis

Settings for analyzed fields are applied at the data source level.

1. Run Explain Data on a mark when editing a view.
2. In the Data Guide pane, click the settings icon at the bottom of the pane. Or, click the **Edit** button in the Analyzed Fields view ([how to open analyzed fields](#)).

3. In the Explain Data Settings dialog box, click the **Fields** tab.
4. Click a drop-down arrow next to a field name, select **Automatic** or **Never Include**, and then click **OK**.

Note that fields must have less than 500 unique values to be included in the analysis.

Fields excluded by default

Fields excluded by default

All unvisualized measures when there are more than 1,000 measures in the data source.

All unvisualized dimensions when there are more than 1,000 dimensions in the data source.

Reasons for exclusion

Computing explanations for more than 1000 unvisualized measures or dimensions can take longer to compute, sometimes several minutes. These fields are excluded by default for initial analysis, but you can choose to include them for further analysis.

In this situation, you might see an alert asking if you want Explain Data to consider more fields. Click the alert link to get more information. Click **Explain All** to run an analysis that includes more fields.

Fields excluded by default	Reasons for exclusion
Fields that use geometry, latitude, or longitude	Geometry, latitude, or longitude by themselves can never be explanations. It is highly likely that an explanation that calls out the latitude or the longitude as an explanation is due to a spurious correlation and not a probable explanation.
Dimensions with high cardinality (dimensions with > 500 members)	High cardinality dimensions take longer to compute. Dimensions with more than 500 unique values will not be considered for analysis.
Groups, bins, or sets	Not currently supported.
Table calculations	Table calculations cannot be analyzed when table calculations are at a different level of detail than the view.
Unvisualized measures that can't be averaged	Unvisualized measures that can't be averaged include measures that are calculated fields where the calculation expression includes aggregations (display as AGG() fields when added to the sheet).
Discrete measures and continuous dimensions	Not currently supported.
Hidden fields	Not available.
Calculated fields with errors	No values present to analyze.

Requirements and Considerations for Using Explain Data

Explain Data is always available to authors in Tableau Desktop.

For Tableau Cloud and Tableau Server: When Explain Data is enabled for a site, Creators and Explorers with the appropriate permissions can run Explain Data when editing a work-

book. All users with the appropriate permissions can run Explain Data in viewing mode in published workbooks. For more information, see [Control Access to Explain Data](#).

What makes a viz a good candidate for Explain Data

Explain Data works best on visualizations that require deeper exploration and analysis, rather than infographic-style, descriptive vizzes that communicate summarized data.

- Row-level data is necessary for Explain Data to create models of your data and generate explanations. Vizzes with underlying, row-level data, where relationships might exist in unvisualized fields are good candidates for running Explain Data.
- Vizzes based on pre-aggregated data without access to row-level data are not ideal for the statistical analysis performed by Explain Data.

What data works best for Explain Data

When you are using Explain Data in a worksheet, remember that Explain Data works with:

- **Single marks only**—Explain Data analyzes single marks. Multiple mark analysis is not supported.
- **Aggregated data**—The view must contain one or more measures that are aggregated using SUM, AVG, COUNT, or COUNTD. At least one dimension must also be present in the view.
- **Single data sources only**—The data must be drawn from a single, primary data source. Explain Data does not work with blended or cube data sources.

When preparing a data source for a workbook, keep the following considerations in mind if you plan to use Explain Data during analysis.

- Use a data source with underlying data that is sufficiently wide. An ideal data set has at least 10-20 columns in addition to one (or more) aggregated measures to be explained.
- Give columns (fields) names that are easy to understand.
- Eliminate redundant columns and data prep artifacts. For more information, see [Change fields used for statistical analysis](#).
- Don't discard unvisualized columns in the data source. Explain Data considers fields in the underlying data when it analyzes a mark.

- Low cardinality dimensions work better. The explanation of a categorical dimension is easier to interpret if its cardinality is not too high (< 20 categories). Dimensions with more than 500 unique values will not be considered for analysis.
- Don't pre-aggregate data as a general rule. But if the data source is massive, consider pre-aggregating the data to an appropriate level of detail.
- Use extracts over live data sources. Extracts run faster than live data sources. With live data sources, the process of creating explanations can create many queries (roughly one query per each candidate explanation), which can result in explanations taking longer to be generated.

Situations where Explain Data is not available

Sometimes Explain Data will not be available for a selected mark, depending on the characteristics of the data source or the view. If Explain Data cannot analyze the selected mark, the Explain Data icon and context menu command will not be available.

Explain Data can't be run in views that use:

- Map coordinate filters
- Blended data sources
- Data sources with parameters
- Data sources that don't support COUNTD or COUNT(DISTINCT ...) syntax, such as Access.
- Filters on aggregate measures
- Disaggregated measures

Explain Data can't be run if you select:

- Multiple marks
- Axis
- Legend
- Grand total
- Trend line or reference line
- A mark in a view that contains a very low number of marks

Explain Data can't be run when the measure to be used for an explanation:

- Isn't aggregated using SUM, AVG, COUNT, COUNTD
- Is a table calculation
- Is used in measure values

Explain Data can't offer explanations for a dimension when it is:

- A calculated field
 - A parameter
 - Used in Measure Names and Measure Values
 - A field with more than 500 unique values.
- Dimensions with more than 500 unique values will not be considered for analysis.

Control Access to Explain Data

Your access to Explain Data will vary depending on your site role and content permissions. Explain Data is always available to authors in Tableau Desktop. Authors with appropriate permissions can run Explain Data in editing mode in Tableau Cloud and Tableau Server.

Authors can also control whether Explain Data is available in viewing mode in published workbooks and which explanation types are displayed.

Be aware that Explain Data can surface values from dimensions and measures in the data source that aren't represented in the view. As an author, you should run Explain Data and test the resulting explanations to make sure that sensitive data isn't being exposed in your published workbooks.

Who can access Explain Data

Explain Data is enabled by default at the site level. Server administrators (Tableau Server) and site administrators (Tableau Cloud) can control whether Explain Data is available for a site. For more information, [Disable or Enable Explain Data for a Site](#).

Mode	Who Can Access
Viewing mode	Tableau Viewers , Explorers , and Creators who have the Run Explain Data permission capability can run and explore Explain Data explanations in viewing mode.
Editing mode	Tableau Creators can run Explain Data when editing a view in Tableau Desktop, Tableau Cloud, or Tableau Server. Explorers who have the Run Explain Data permission cap-

Mode	Who Can Access
	<p>ability and editing permissions can run Explain Data when editing a workbook in Tableau Cloud or Tableau Server.</p> <p>Creators and Explorers who have editing permissions can open new worksheets for further analysis.</p> <p>They also can use Explain Data Settings to control who can use Explain Data and what they can see.</p>

Control who can use Explain Data and what they can see

A combination of settings must be enabled to make Explain Data available in editing mode and viewing mode in Tableau Cloud and Tableau Server.

Editing mode

Requirements for authors to run Explain Data or edit Explain Data settings in editing mode:

- Site setting: **Availability of Explain Data** set to **Enable**. Enabled by default.
- Site role: Creator, Explorer (can publish)
- Permissions: **Run Explain Data** capability set to **Allowed**. Unspecified by default. If you open a workbook (Tableau version 2022.1 or earlier) that used this permission in Tableau version 2022.2 or later, you will need to reset the Run Explain Data capability to Allowed.

Note: The **Download Full Data** capability for a Creator or Explorer (can publish) controls whether they see the View Full Data option in Extreme Values explanations. Viewers are always denied the Download Full Data capability. However, all users can see record-level details when the Extreme Values explanation type is enabled in Explain Data settings.

Creators and Explorers with editing permissions and the Run Explain Data permission capability can access **Explain Data Settings**, which provide options for controlling:

- The **explanation types that are displayed** in the Data Guide pane.
- The **fields that are included in, or excluded from** statistical analysis.

These options are set for the entire workbook and can only be set in the Explain Data Settings dialog box.

Viewing mode

Requirements for all users to run Explain Data in viewing mode:

- Site setting: **Availability of Explain Data** set to **Enable**. Enabled by default.
- Site role: Creator, Explorer, or Viewer
- Permissions: **Run Explain Data** capability set to **Allowed**. Unspecified by default. If you open a workbook (Tableau version 2022.1 or earlier) that used this permission in Tableau version 2022.2 or later, you will need to reset the Run Explain Data capability to Allowed.

Note: To see explanations of Detected Outliers in the Data Guide, users of a viz must have the Explain Data permission allowed for the workbook or view. The owner of the workbook will need to open the permissions settings for this workbook in Tableau Server or Tableau Cloud and allow the Explain Data permission to that user.

Open the Explain Data Settings dialog box

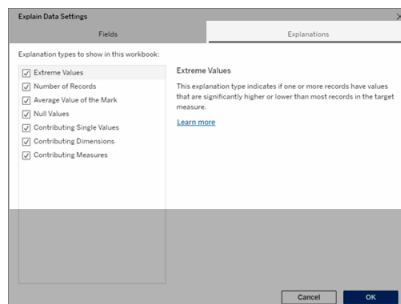

1. From the **Analysis** menu, choose **Explain Data Settings**. Or, in the Data Guide pane, click the settings icon (bottom right).

Include or exclude explanation types displayed by Explain Data

Creators and Explorers who have editing permissions can choose to exclude (or include) explanation types displayed for all workbook users.

1. In the **Explain Data Settings** dialog box, click the **Explanation Types** tab.

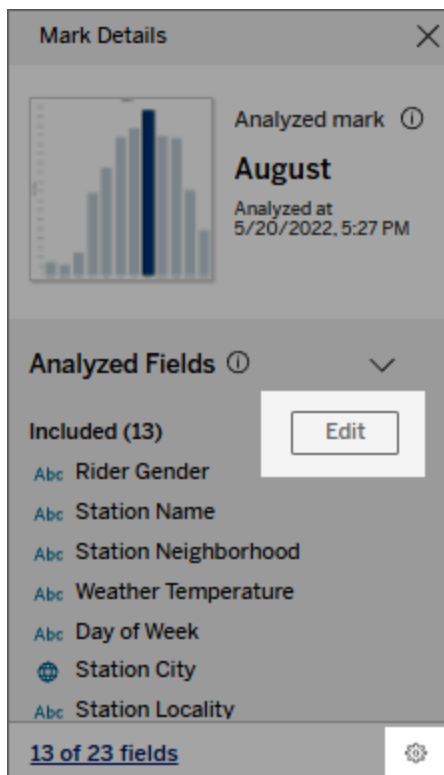

2. In the list of explanation types, select or clear an explanation type.
3. Click **OK**.

Test the setting by saving and closing the published workbook, and then opening a view from the workbook in viewing mode. Select a mark that typically has Extreme Value explanations, and then run Explain Data to check the explanation results.

Include or exclude fields used for statistical analysis

Creators or Explorers who have editing permissions can choose to exclude (or include) fields that are eligible for analysis.

1. In the Data Guide pane (bottom right), choose the settings icon. Or, choose the **Edit** button in the [Analyzed Fields view](#).

2. In the [Explain Data Settings](#) dialog box, click the **Fields** tab.
3. In the list of fields under **Include**, click the drop-down arrow and select **Automatic** to include an eligible field every time Explain Data runs for that workbook.

Note that fields must have less than 500 unique values to be included in the analysis.

Select **Never Include** to explicitly exclude the field.

Select **Include None** to run a statistical analysis on the data without considering fields.

Select **Reset** to return to the default settings.

4. Click **OK**.

Test the setting by saving the published workbook. Select a mark, and then run Explain Data to check the explanation results.

Configure Tableau to allow users to share explanations via email and Slack

Tableau administrators can control whether explanations can be shared in viewing mode via email or Slack to other Tableau users.

Follow these steps to allow notifications and sharing via email and Slack in Tableau Cloud or Tableau Server:

1. Click **Settings**.
2. On the General tab, scroll down to **Manage Notifications**.
3. For Collaboration, select **Share** for **On Tableau**, **Email**, and **Slack**.

To share explanations via Slack, the Tableau app must be set up for your Slack workspace. Sharing explanations with Slack is enabled by default in Tableau Cloud.

In Tableau Server, an administrator will need to set up the Tableau app for Slack. For more information, see [Integrate Tableau with a Slack Workspace](#).

How Explain Data Works

Use Explain Data as an incremental, jumping-off point for further exploration of your data. The possible explanations that it generates help you to see the different values that make up or relate to an analyzed mark in a view. It can tell you about the characteristics of the data points in the data source, and how the data might be related (correlations) using statistical modeling. These explanations give you another tool for inspecting your data and finding interesting clues about what to explore next.

Note: Explain Data is a tool that uncovers and describes relationships in your data. It can't tell you what is causing the relationships or how to interpret the data. **You are the expert on your data.** Your domain knowledge and intuition is key in helping you decide what characteristics might be interesting to explore further using different views.

For related information on how Explain Data works, and how to use Explain Data to augment your analysis, see these Tableau Conference presentations:

- [From Analyst to Statistician: Explain Data in Practice \(1 hour\)](#)
- [Leveraging Explain Data \(45 minutes\)](#)

What Explain Data is (and isn't)

Explain Data is:

- A tool and a workflow that leverages your domain expertise.
- A tool that surfaces relationships in your data and recommends where to look next.
- A tool and a workflow that helps expedite data analysis and make data analysis more accessible to a broader range of users.

Explain Data is not:

- A statistical testing tool.
- A tool to prove or disprove hypotheses.
- A tool that is giving you an answer or telling you anything about causality in your data.

When running Explain Data on marks, keep the following points in mind:

- **Consider the shape, size, and cardinality of your data.** While Explain Data can be used with smaller data sets, it requires data that is sufficiently wide and contains enough marks (granularity) to be able to create a model.
- **Don't assume causality.** Correlation is not causation. Explanations are based on models of the data, but are not causal explanations.

A correlation means that a relationship exists between some data variables, say A and B. You can't tell just from seeing that relationship in the data that A is causing B, or B is causing A, or if something more complicated is actually going on. The data patterns are exactly the same in each of those cases and an algorithm can't tell the difference between each case. Just because two variables seem to change together doesn't necessarily mean that one causes the other to change. A third factor could be causing them both to change, or it may be a coincidence and there might not be any causal relationship at all.

However, you might have outside knowledge that is not in the data that helps you to identify what's going on. A common type of outside knowledge would be a situation where the data was gathered in an experiment. If you know that B was chosen by flipping a coin, any consistent pattern of difference in A (that isn't just random noise) must be caused by B. For a longer, more in-depth description of these concepts, see the article [Causal inference in economics and marketing](#) by Hal Varian.

How explanations are analyzed and evaluated

Explain Data runs a statistical analysis on a dashboard or sheet to find marks that are outliers, or specifically on a mark you select. The analysis also considers possibly related data points

from the data source that aren't represented in the current view.

Explain Data first predicts the value of a mark using only the data that is present in the visualization. Next, data that is in the data source (but not in the current view) is considered and added to the model. The model determines the range of predicted mark values, which is within one standard deviation of the predicted value.

What is an expected range?

The expected value for a mark is the median value in the expected range of values in the underlying data in your viz. The expected range is the range of values between the 15th and 85th percentile that the statistical model predicts for the analyzed mark. Tableau determines the expected range each time it runs a statistical analysis on a selected mark.

Possible explanations are evaluated on their explanatory power using statistical modeling. For each explanation, Tableau compares the expected value with the actual value.

value	Description
Higher than expected / Lower than expected	If an expected value summary says the mark is <i>lower than expected</i> or <i>higher than expected</i> , it means the aggregated mark value is outside the range of values that a statistical model is predicting for the mark. If an expected value summary says the mark is <i>slightly lower</i> or <i>slightly higher</i> than expected, or <i>within the range of natural variation</i> , it means the aggregated mark value is within the range of predicted mark values, but is lower or higher than the median.
Expected Value	If a mark has an expected value, it means its value falls within the expected range of values that a statistical model is predicting for the mark.
Random Variation	When the analyzed mark has a low number of records, there may not be enough data available for Explain Data to form a statistically significant explanation. If the mark's value is outside the expected range, Explain Data can't determine whether this unexpected value is being caused by random variation or by a meaningful difference in

value	Description
	the underlying records.
No Explanation	When the analyzed mark value is outside of the expected range and it does not fit a statistical model used for Explain Data, no explanations are generated.

Models used for analysis

Explain Data builds models of the data in a view to predict the value of a mark and then determines whether a mark is higher or lower than expected given the model. Next, it considers additional information, like adding additional columns from the data source to the view, or flagging record-level outliers, as potential explanations. For each potential explanation, Explain Data fits a new model, and evaluates how unexpected the mark is given the new information. Explanations are scored by trading off complexity (how much information is added from the data source) against the amount of variability that needs to be explained. Better explanations are simpler than the variation they explain.

Explanation type	Evaluation
Extreme values	<p>Extreme values are aggregated marks that are outliers, based on a model of the visualized marks. The selected mark is considered to contain an extreme value if a record value is in the tails of the distribution of the expected values for the data.</p> <p>An extreme value is determined by comparing the aggregate mark with and without the extreme value. If the mark becomes less surprising by removing a value, then it receives a higher score.</p> <p>When a mark has extreme values, it doesn't automatically mean it has outliers, or that you should exclude those records from the view. That choice is up to you depending on your analysis. The explanation is simply pointing out an interesting extreme value in</p>

Explanation type	Evaluation
	<p>the mark. For example, it could reveal a mistyped value in a record where a banana cost 10 dollars instead of 10 cents. Or, it could reveal that a particular sales person had a great quarter.</p>
Number of records	<p>The number of records explanation models the aggregate sum in terms of the aggregate count; average value of records models it in terms of the aggregate average. The better the model explains the sum, the higher the score.</p> <p>This explanation describes whether the sum is interesting because the count is high or low, or because the average is high or low.</p>
Average value of the mark	<p>This type of explanation is used for aggregate marks that are sums. It explains whether the mark is consistent with the other marks because in terms of its aggregate count or average, noting the relation $SUM(X) = COUNT(X) * AVG(X)$.</p> <p>This explanation describes whether the sum is interesting because the count is high or low, or because the average is high or low.</p>
Contributing Dimensions	<p>This explanation models the target measure of the analyzed mark in terms of the breakdown among categories of the unvisualized dimension. The analysis balances the complexity of the model with how well the mark is explained.</p> <p>An <i>unvisualized dimension</i> is a dimension that exists in the data source, but isn't currently being used in the view. This type of explanation is used for sums, counts and averages.</p> <p>The model for unvisualized dimensions is created by splitting out marks according to the categorical values of the explaining column, and then building a model with the value that includes all of the data points in the source visualization. For each row, the model</p>

Explanation type	Evaluation
	<p>attempts to recover each of the individual components that made each mark. The analysis indicates whether the model predicts the mark better when components corresponding to the unvisualized dimension are modeled and then added up, versus using a model where the values of the unvisualized dimension are not known.</p> <p>Aggregate dimension explanations explore how well mark values can be explained without any conditioning. Then, the model conditions on values for each column that is a potential explanation. Conditioning on the distribution of an explanatory column should result in a better prediction.</p>
Contributing Measures	<p>This explanation models the mark in terms of this unvisualized measure, aggregated to its mean across the visualized dimensions. An <i>unvisualized measure</i> is a measure that exists in the data source, but isn't currently being used in the view.</p> <p>A Contributing Measures explanation can reveal a linear or quadratic relationship between the unvisualized measure and the target measure.</p>

Disable or Enable Explain Data for a Site

Explain Data is enabled for sites by default, but Tableau administrators may disable it.

1. Go to the **General** site settings.
2. (Tableau Server only) In the **Web Authoring** section, select **Let users edit workbooks in their browser**.
3. In the **Availability of Explain Data** section, select from these options:
 - **Enable** lets Creators and Explorers with the appropriate permissions run Explain Data in editing mode. Lets all users with appropriate permissions run

Explain Data when it is enabled for viewing mode.

- **Disable** prevents all users from running Explain Data or accessing Explain Data settings in workbooks.

Use Dashboard Extensions

Extensions let you add unique features to dashboards or directly integrate them with applications outside Tableau. Adding extensions is easy; you incorporate them into dashboard layouts just like other dashboard objects.

Extensions expand dashboard functionality with the help of web applications created by third-party developers. If you're a developer and want to create your own extensions, see the [Tableau Extensions API documentation](#) on GitHub.

Note: Tableau administrators can turn off dashboard extensions for [Tableau Desktop](#), [Tableau Server](#), and [Tableau Cloud](#).

Add an extension to a dashboard

1. In a Tableau workbook, open a dashboard sheet.
2. From the **Objects** section, drag **Extension** to the dashboard.

3. In the “Add an Extension” dialog box, do either of the following:

- Search for and select an extension.
 - Click **Access Local Extensions**, and navigate to a .trex file you previously downloaded.
4. If prompted, allow or deny the dashboard extension access to data in the workbook. For more information, see [Data security](#), [Network-enabled](#), and [Sandboxed extensions](#).

If you allow access, follow any on screen instructions for configuring the extension.

Note: If you're using Tableau Server or Tableau Cloud, Extension objects will appear blank in prints, PDFs, and images of dashboards (including images in subscription emails).

Configure a dashboard extension

Some dashboard extensions provide configuration options that let you customize features.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **Configure**.

2. Follow the on-screen instructions to configure the extension.

Reload a dashboard extension

If a dashboard extension becomes unresponsive, you might need to reload it, which is similar to refreshing a web page in a browser.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **Reload**.

The dashboard extension is refreshed and set to its original state.

2. If reloading the extension fails to return it to a useable state, try removing it from the dashboard and adding it again.

Data security, Network-enabled, and Sandboxed extensions

Dashboard extensions are web applications that come in two forms:

- *Network-enabled extensions* run on web servers located outside of your local network.
- *Sandboxed extensions* run in a protected environment without access to any other resource or service on the web.

Before adding a Network-enabled extension or viewing a dashboard with one, be certain that you trust the website that hosts it. By default, dashboard extensions use the HTTPS protocol, which guarantees an encrypted channel for sending and receiving data, and ensures some privacy and security.

For more information about data security when using dashboard extensions, see [Extension Security - Best Practices for Deployment](#).

Allow or deny data access to a Network-enabled extension

Depending on how an extension is designed, it can access either visible data in a view, or full underlying data, table and field names from data sources, and information about data source connections. When you add an extension, or view a dashboard with one, you're given an opportunity to allow or deny the extension to run and access this data.

If you're viewing a dashboard with an extension that requires full data access, and that access has been denied, a message appears in place of the extension. If you trust the extension and want to use it, you can reset permissions and allow the extension to run.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **Reset Permissions**.

2. Click either **Allow** to let the extension run and access data, or **Deny** to prevent the extension from running.

Ensure that JavaScript is enabled in Tableau Desktop

Dashboard extensions interact with data using the Tableau Extensions API library, a JavaScript library. If you want to use extensions, be sure that JavaScript is enabled in the dashboard security settings:

Choose **Help > Settings and Performance > Set Dashboard Web View Security > Enable JavaScript**.

Ensure that extensions run on Tableau Cloud or Tableau Server

You can add extensions to workbooks you publish from Tableau Desktop or directly in the web-authoring mode of Tableau Cloud and Tableau Server. A Tableau administrator must allow extensions to run on a site and add Network-enabled extensions to a safe list. Administrators should only allow extensions that you have tested and trust.

If you want to use a dashboard extension on Tableau Cloud or Tableau Server, direct your administrator to [Manage Dashboard Extensions in Tableau Cloud](#) or [Manage Dashboard Extensions in Tableau Server](#).

Supported web browsers for Sandboxed extensions

Sandboxed extensions run in all browsers supported [Tableau Server](#) and [Tableau Cloud](#) except Internet Explorer 11.

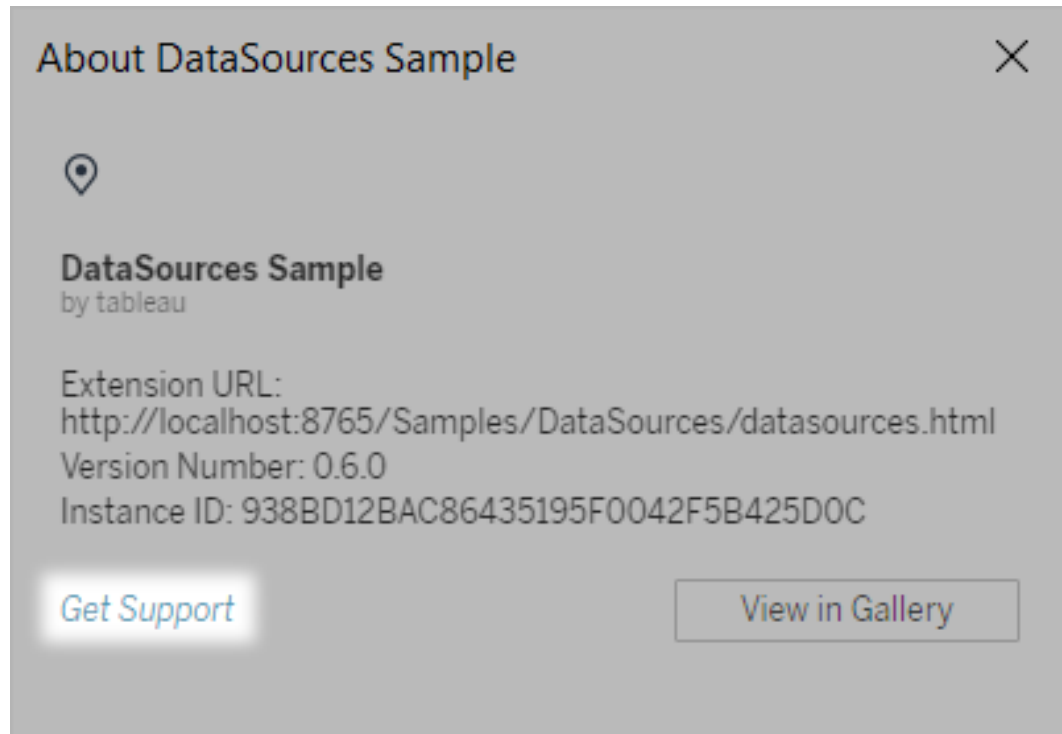

Supported versions of Tableau Server for Sandboxed extensions

You can use Sandboxed extensions in Tableau Server 2019.4 and later.

Get support for dashboard extensions

To get help for an extension, you'll need to contact the developer or company who created it.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **About**.
2. Click **Get Support** to go to the support page of the extension developer.

Note: Tableau doesn't provide support for extensions or for other programs that interface with the Extensions API. However, you can submit questions and ask for help in the [Tableau developer community](#).

Format Animations

Animate visualizations to better highlight changing patterns in your data, reveal spikes and outliers, and see how data points cluster and separate.

Animations visually transition between filter, sort, and zoom settings, different pages, and changes to filter, parameter, and set actions. As visualizations animate in response to these

changes, viewers can more clearly see how data differs, helping them make better informed decisions.

Understanding simultaneous and sequential animations

When you author animations, you can choose between two different styles: simultaneous or sequential. Here are examples of each type.

Simultaneous animations

The default simultaneous animations are faster and work well when showing value changes in simpler charts and dashboards.

Click the image above to replay the animation.

Sequential animations

Sequential animations take more time but make complex changes clearer by presenting them step-by-step.

Click the image above to replay the animation.

Animate visualizations in a workbook

When you create a new workbook, Tableau enables animations for your viz by default. You can turn animations on or off at the user and workbook level.

1. Choose **Format > Animations**.
2. If you want to animate every sheet, under **Workbook Default**, click **On**. Then do the following:
 - For **Duration**, choose a preset, or specify a custom duration of up to 10 seconds.
 - For **Style**, choose **Simultaneous** to play all animations at once or **Sequential** to fade out marks, move and sort them, and then fade them in.
3. To override workbook defaults for a particular sheet, change the settings under **Selected Sheet**.

Note: In the Selected Sheet section, “(Default)” indicates a setting that auto-

matically reflects the related Workbook Default setting.

Sequential ▼

To replay an animation, click the **Replay** button in the toolbar. From the **Replay** button, you can also choose the speed at which the animation replays: actual speed, 2x speed, or 1/2 speed.

Reset animation settings for a workbook

You can reset animations to return an entire workbook to the default animation settings. Be aware that this turns animations off by default.

1. Choose **Format > Animations**.
2. In the middle of the **Animations** pane, click **Reset All Sheets**.

Completely disable all animations

When you create a new workbook, animations are enabled by default. If you find animations distracting while viewing vizs, you can completely disable them so they never play. (This isn't a system-wide setting; each user needs to apply it separately.)

- In Tableau Desktop, choose **Help > Settings and Performance**, and deselect **Enable Animations**.
- In Tableau Cloud or Tableau Server, click your profile image or initials in the top right corner of the browser, and choose **My Account Settings**. Then scroll down to the bottom of the page, deselect **Enable animations**, and click **Save Changes**.

Note: When animations are disabled, you can still choose **Format > Animations** in authoring mode and adjust settings—but they will have no effect.

Format decimals for axes animations

If the number of decimal places for a measure is set to the default, then the number of decimals shown during the axis animation might fluctuate during the axes animation. To avoid this, format the number of decimal places displayed for a measure. For more information, see [Format Numbers and Null Values](#).

Why animations won't play

Server rendering

Animations won't play if a viz is server-rendered. To ensure that vizzes render on a client computer or mobile device, use these techniques:

- If you're a viz author, [reduce viz complexity](#).
- If you're a Tableau Server administrator, [increase the complexity threshold for client-side rendering](#).

Note: On computers with lower processing power, animations may appear choppy, but users can continue to interact with vizzes without any delays in responsiveness.

Unsupported browsers and features

Animations are supported by all web browsers except Internet Explorer.

The following Tableau features don't animate:

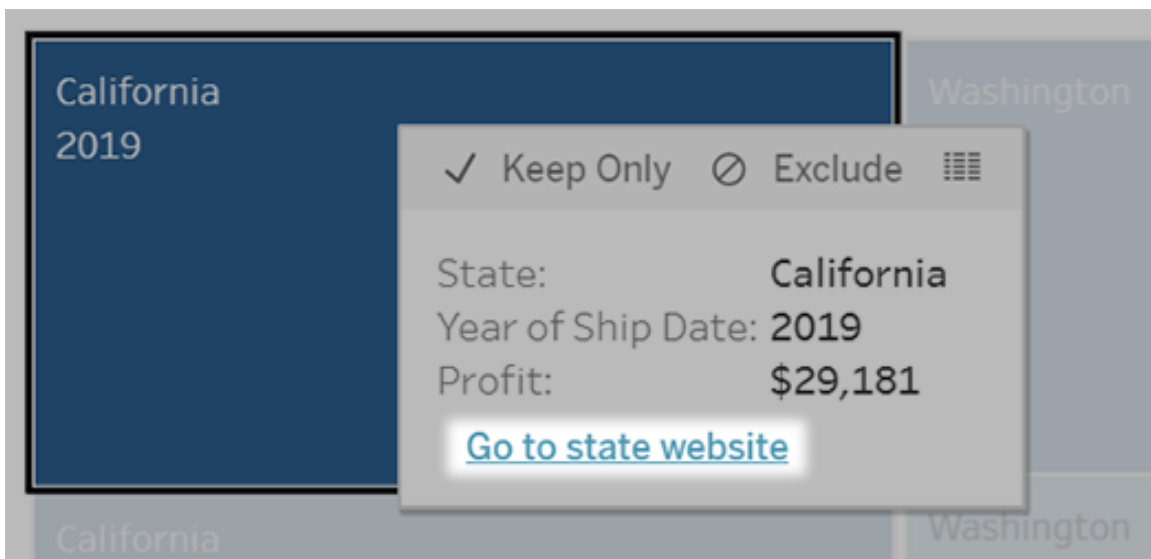

- Maps, polygons, and density marks in web browsers
- Pie and text marks
- Headers
- Forecasts, trends, and reference lines

- Page history trails (If a viz includes these, turn off animations to avoid unexpected behavior.)

URL Actions

A URL action is a hyperlink that points to a web page, file, or other web-based resource outside of Tableau. You can use URL actions to create an email or link to additional information about your data. To customize links based on your data, you can automatically enter field values as parameters in URLs.

Tip: URL actions can also open in a web page object in a dashboard. See [Actions and Dashboards](#) to learn more.

A URL action run from a tooltip menu. The link reflects the action name, not the target URL.

Open a web page with a URL action

1. On a worksheet, select **Worksheet > Actions**. From a dashboard, select **Dashboard > Actions**.
2. In the Actions dialog box, click **Add Action** and then select **Go to URL**.
3. In the next dialog box, enter a name for the action. To enter field variables in the name, click the **Insert** menu to the right of the **Name** box.

Note: Give the action a descriptive name, because the link text in the tooltip is the name of the action, not the URL. For example, when linking to more product details, a good name could be "Show More Details".

4. Use the drop-down list to select a source sheet or data source. If you select a data source or dashboard you can select individual sheets within it.

5. Select how users will run the action.

If you choose this option...

	The action is run when the user...
Hover	Mouses over a mark in the view. This option works best for highlight actions within a dashboard.
Select	Clicks a mark in the view. This option works well for all types of actions.
Menu	Right-clicks (control-clicks on Mac) a selected mark in the view, then clicks an option in a tooltip (menu). This option works particularly well for URL actions.

6. For URL Target, specify where the link will open:
 - **New Tab if No Web Page Object Exists** — Ensures that the URL opens in a browser on sheets that lack web page objects. This is a good choice when Source Sheets is set to All or a data source.
 - **New Browser Tab** — Opens in the default browser.

- **Web Page Object** — (Available only for dashboards with Web Page objects)
Opens in the web page object you select.

URL Target

☐ New Tab if No Web Page Object Exists

☐ New Browser Tab

☒ Web Page Object

 en.wikipedia.org ▼

7. Enter a URL

- The URL should start with one of the following prefixes: `http`, `https`, `ftp`, `mailto`, `news`, `gopher`, `tsc`, `tsl`, `sms`, or `tel`

Note: If no prefix is entered, `http://` is automatically appended to the beginning and the URL action will work in Tableau Desktop. However, if a URL action with no prefix is published to Tableau Server or Tableau Cloud, it will fail in the browser. Always provide a fully qualified URL for actions if the dashboard will be published.

Note: You can specify an ftp address only if the dashboard doesn't contain a web object. If a web object exists, the ftp address won't load.

- Tableau Desktop also supports local paths like `C:\Example folder-example.txt`, as well as file URL actions.
- To enter field and filter values as dynamic values in the URL, click the **Insert** menu to the right of the URL. Be aware that any referenced fields must be used in the view. For details, see [Using field and filter values in URLs](#).

▼ Data Values

[Learn more](#)

☒ Encode data values that URLs do not support

☒ Allow multiple values via URL parameters

Value Delimiter

Delimiter Escape Character

.

/

Below the URL you enter is a hyperlinked example you can click for testing.

8. (Optional) In the Data Values section, select any of the following options:
 - **Encode Data Values that URLs Do Not Support** — Select this option if your data contains values with characters that browsers don't allow in URLs. For example, if one of your data values contains an ampersand, such as “Sales & Finance,” the ampersand must be translated into characters that your browser understands.
 - **Allow Multiple Values via URL Parameters** — Select this option if you are linking to a web page that can receive lists of values via parameters in the URL. For example, say you select several products in a view and you want to see each product's details hosted on a webpage. If the server can load multiple product details based on a list of identifiers (product ID or product name), you could use multi-select to send the list of identifiers as parameters.

When you allow multiple values, you must also define the delimiter escape character, which is the character that separates each item in the list (for example, a comma). You must also define the Delimiter Escape, which is used if the delimiter character is used in a data value.

Create an email with a URL action

1. On a worksheet, select **Worksheet > Actions**. From a dashboard, select **Dashboard > Actions**.
2. In the Actions dialog box, click **Add Action**, and select **Go to URL**.
3. In the Source Sheets drop-down list, select the sheet that contains the field with the email addresses you want to send to.
4. In the URL box, do the following:
 - Type **mailto:**, and click the **Insert** menu at right to select the data field that contains email addresses.
 - Type **?subject=**, and enter text for the Subject line.
 - Type **&body=**, and click the **Insert** menu at right to select the fields of information that you want to include in the body of the email.

In the example below, the “Email” field contains the email addresses, the subject is “City Information”, and the body text of the email consists of the city and state data that is associated with the email address.

:

5. (Optional) Display data from your workbook in the body of your email as a vertical list instead of the default horizontal list. For example, suppose you have a horizontal list of cities, such as Chicago, Paris, Barcelona, which you would rather display vertically, like this:

Chicago

Paris

Barcelona

To make the list vertical, in the Data Values section, do the following:

- Deselect **Encode Data Values that URLs Do Not Support**
- Select **Allow Multiple Values via URL Parameters**.
- Type **%0a** in the **Value Delimiter** text box to add line breaks between each item in the list. (These are the URL-encoded characters for a line break.)

Using field and filter values in URLs

When users trigger URL actions from selected marks, Tableau can send field, filter, and parameter values as variables in the URL. For example, if a URL action links to a mapping website, you could insert the address field to automatically open the currently selected address on the website.

1. In the Edit URL Action dialog box, begin typing the URL for the link.
2. Place the cursor where you want to insert a field, parameter, or filter value.
3. Click the **Insert** menu to the right of the text box and select the field, parameter, or filter you want to insert. The variable appears within angle brackets. You can continue adding as many variables as you need.

Note: Any referenced fields must be used in the view. Otherwise, the link won't display in the viz, even if it functions when you click Test Link.

Including aggregated fields

The list of available fields includes only non-aggregated fields. To use aggregated field values as link parameters, first create a related calculated field, and add that field to the view. (If you don't need the calculated field in the visualization, drag it to Detail on the Marks card.)

Inserting parameter values

When inserting parameter values, URL actions send the Display As value by default. To instead send the actual value, add the characters `~na` after the parameter name.

For example, say you have a parameter that includes IP addresses, with Actual Value strings such as `10.1.1.195` and Display As strings with more friendly values such as `Computer A (10.1.1.195)`. To send the actual value, you'd revise the parameter in the URL to look like this: `http://<IPAddress~na>/page.htm`.

Create a Subscription to a View or Workbook

Subscriptions email you an image or PDF snapshot of a view or workbook at regular intervals—without requiring you to sign in to Tableau Server.

Note: Administrators determine whether subscriptions are turned on for a site.

If Tableau Catalog is turned on for a site, administrators can also determine whether subscription emails include relevant upstream data quality warnings. Tableau Catalog is available as part of the Data Management offering. For more information, see [About Tableau Catalog](#).

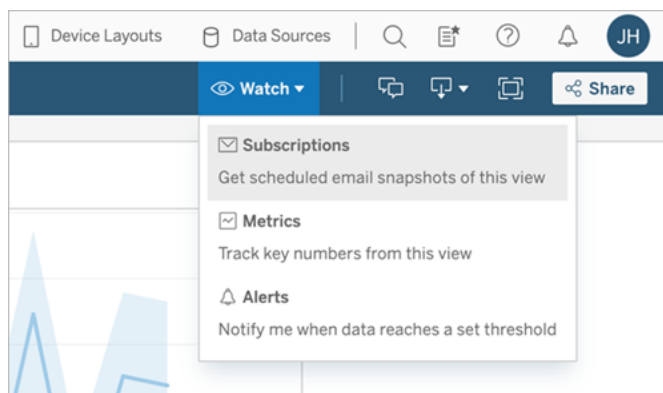

Set up a subscription for yourself or others

When you open a view in Tableau Server, if you see a subscription icon (✉+) in the toolbar, you can subscribe to that view or to the entire workbook. You can subscribe other users who have permission to view the content if you own a workbook, if you are a project leader with an appropriate site role, or if you are an administrator.

1. From the Explore section of your site, select **All Workbooks** or **All Views**, or open the project that contains the view you want to subscribe to.

- Open a view either directly, or after opening the containing workbook.
- On the view toolbar, select **Watch** > **Subscriptions**.

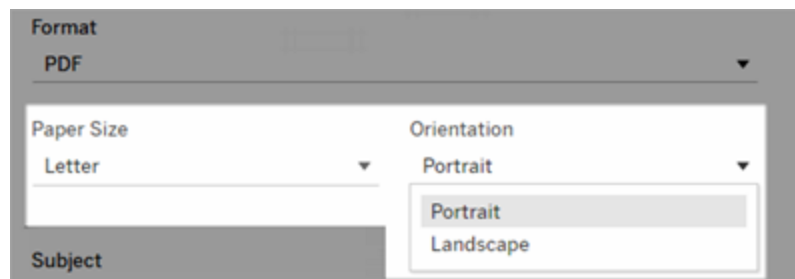

- Add the Tableau users or groups you want to receive the subscription. To receive a subscription, users must have the View and Download Image/PDF permissions and their accounts must also have email addresses.

If you own the workbook, select **Subscribe me**.

Note: When you subscribe a group, each user is added individually at the time the subscription is created. If more users are added to the group later, you must re-subscribe the group for those new users to receive the subscription. Likewise, users later removed from the group will not have their subscriptions removed automatically unless their permissions to the subscribed view are removed.

5. Choose whether subscription emails include the current view or the entire workbook. If the view contains data only when high-priority information exists, select **Don't send if view is empty**.
6. Choose the format for your snapshot: as a PNG image, a PDF attachment, or both.
 - If PDFs, choose the paper size and orientation you'd like to receive.

7. To clarify subscription emails, customize the subject line, and add a message.

Note: To update the subscription message, you must unsubscribe from the existing subscription and create a new subscription with a different message. For more information, see [Update or unsubscribe from a subscription](#).

8. When the workbook uses one data extract on a published connection, you can pick a frequency:

- **When Data Refreshes:** Sends only when data in the view or workbook is refreshed by running refresh schedules.
- **On Selected Schedule:** Pick a schedule for the subscription.

9. If frequency is not set to When Data Refreshes, pick a schedule:

- Choose from subscription schedules established by your administrator.
- For sites with **custom schedules enabled**, click the drop-down arrow to the left of the current settings.

Schedule
> 5 days a week, at 08:00

Then specify a custom schedule that sends subscription emails whenever you wish. (The precise delivery time may vary if server load is high.)

Schedule
▼ 5 days a week, every hour from 09:00 to 17:00

Repeats: Hourly ▼ Every: Hour ▼

From: 09:00 ▼ To: 17:00 ▼

On: ☐ Su ☒ M ☒ T ☒ W ☒ Th ☒ F ☐ Sa

To change the time zone, click the Time Zone link it to go to your account settings page.

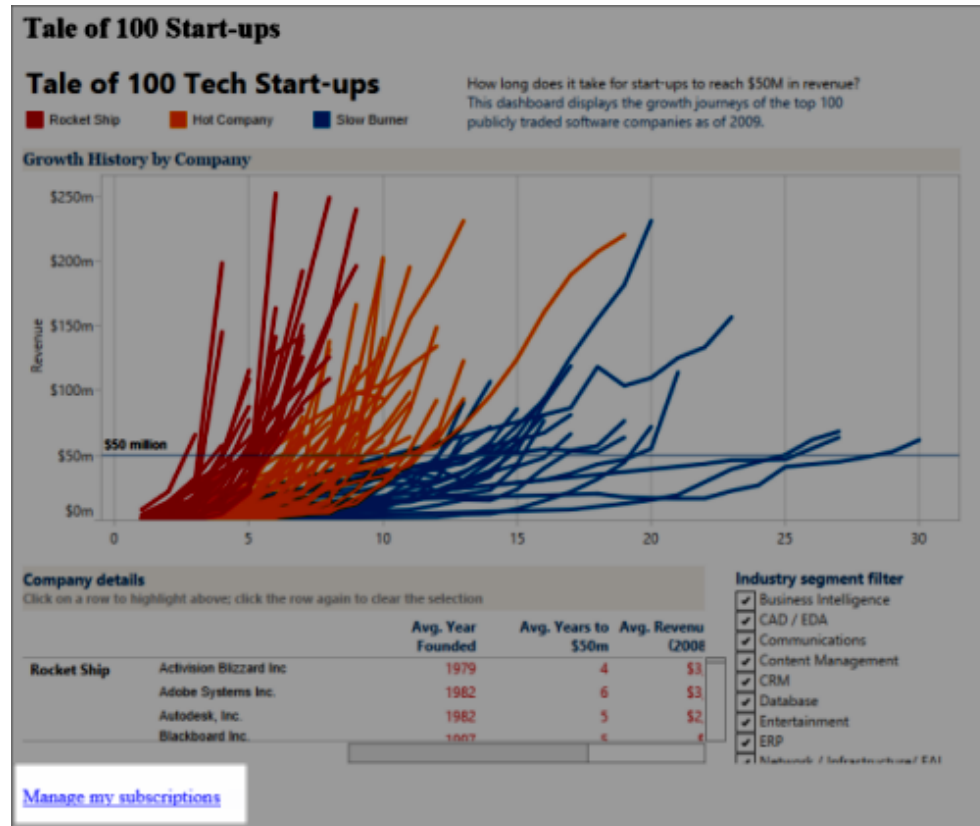

10. Click **Subscribe**.

When you receive a subscription email, you can select the image (or the link in the message body for PDF subscriptions) to be taken to the view or workbook in Tableau Server.

Update or unsubscribe from a subscription

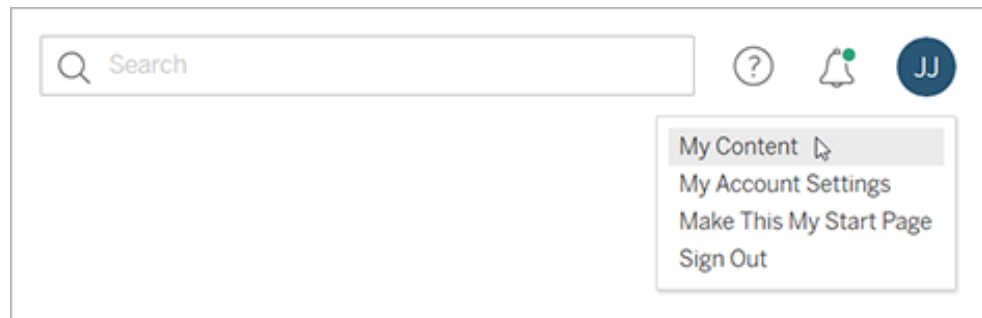

You can unsubscribe from an existing subscription, or make changes to a subscription's format, schedule, subject, or empty view mode.

1. Access your Tableau Server account settings by doing one of the following:
 - Click **Manage my subscriptions** at the bottom of a subscription email.

- Sign in to Tableau Server. At the top of the page, select your user icon, and then

select **My Content**.

2. Click **Subscriptions**.
3. Select the check box next to the view you want to unsubscribe from, click **Actions**, and then click **Unsubscribe**, or select the subscription option you'd like to change.

Resume or delete suspended subscriptions

Sometimes, subscriptions fail because of an issue with the workbook or a problem loading the view. If a subscription fails more than five times, you'll receive a notification email that your subscription has been suspended. There are a few ways to resume a suspended subscription if you're a subscription owner or administrator:

- From the My Content area of Tableau web pages, an icon appears in the Last update column to indicate that the subscription is suspended. Select ... > **Resume Subscription** to resume.
- From the Subscriptions tab of the affected workbook, an icon appears in the last update column to indicate that the subscription is suspended. Select ... > **Resume Subscription** to resume.

You'll receive an email notification when the subscription is working again.

See also

[Change subscription settings](#) in the Tableau Desktop and Web Authoring Help.

[Project-level administration](#) in the Tableau Cloud Help, to learn which site roles allow full Project Leader capabilities.

Use Custom Views

A custom view is a shortcut to a specific state of interaction, such as filter selections and sorting, for a published viz. Custom views don't impact the underlying content. They're a good option if you find yourself adjusting the same filters or zooming into the same data every time you look at a viz.

Custom views aren't the same as web editing, which changes the underlying published content itself. See [Edit Tableau Views on the Web](#).

If the custom views are specifically for filter settings, consider using embedding filter parameters in a shared URL. See [Filter a published dashboard by editing the URL](#) from [The Data School](#).

Notes on custom views

- A custom view doesn't modify the content it's built on.
- Deleting the original content deletes its custom views.
- If the original content is updated or republished, the custom view is also updated.

Tip: Some changes to the original content can break the custom view. See [Maintain Content with Custom Views](#) for best practices on modifying content with custom views.

- If a user is removed from the site, any shared custom views they owned are also lost.
- Subscriptions based on custom views may be more fragile than subscriptions based on the original content.

Note: As of the 2022.3 release, Tableau replaced user names in the custom view URL with IDs. Bookmarked URLs still work but are redirected to the new URL schema. This change is to add more company and user data protection.

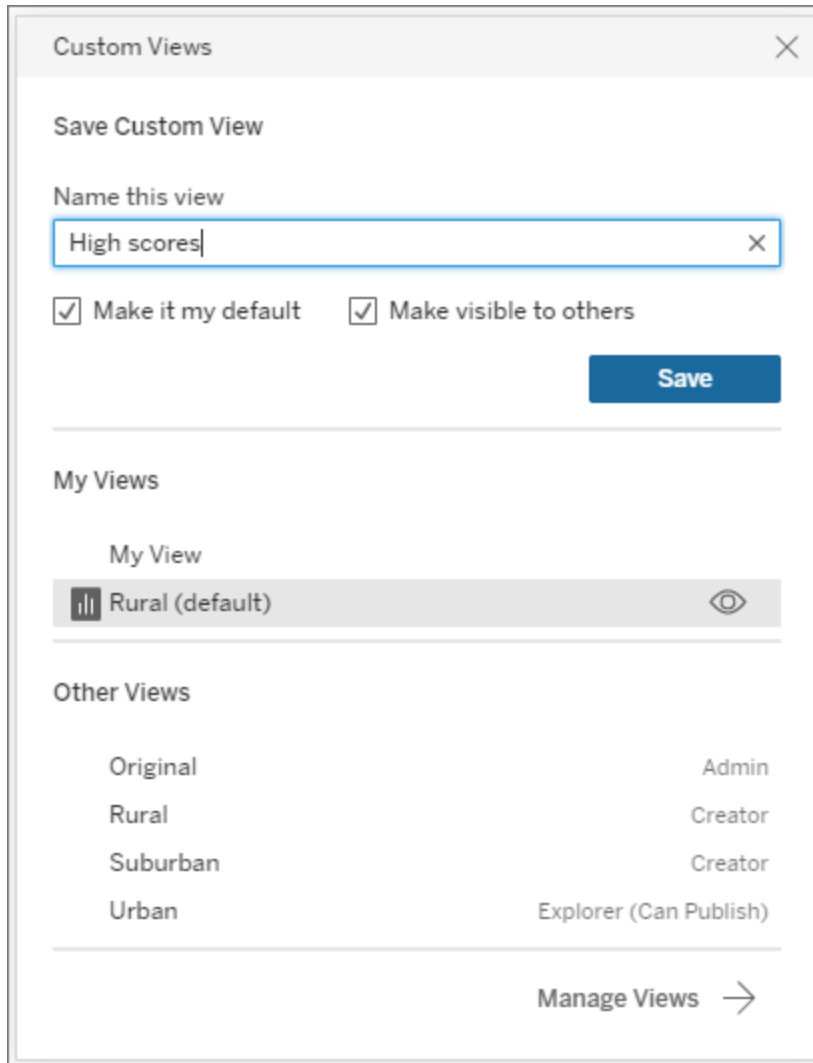

Create a custom view

Start by navigating to the individual view. Make whatever changes you want to capture in the custom view, such as selecting marks, filtering data, or changing sorts.

1. In the toolbar, select the View icon. If there's room in the toolbar, the name of the custom view you're looking at is shown.

2. In the Custom Views dialog, enter a name for the Custom View.

3. (Optional) Select **Make it my default**.
4. (Optional) Select **Make visible to others**. This makes the custom view available to everyone who can see the original content. However, there are several instances when this option isn't available:
 - The user is a Viewer site role.
 - The site's **User Visibility setting** is set to Limited.
 - The permission capability **Share Customized** is denied on the workbook.
5. Click **Save**.

As you interact with the view in a way that changes the custom view, an asterisk appears on the icon to let you know the view has changed. You can save a new custom view to reflect those adjustments if you want to keep them.

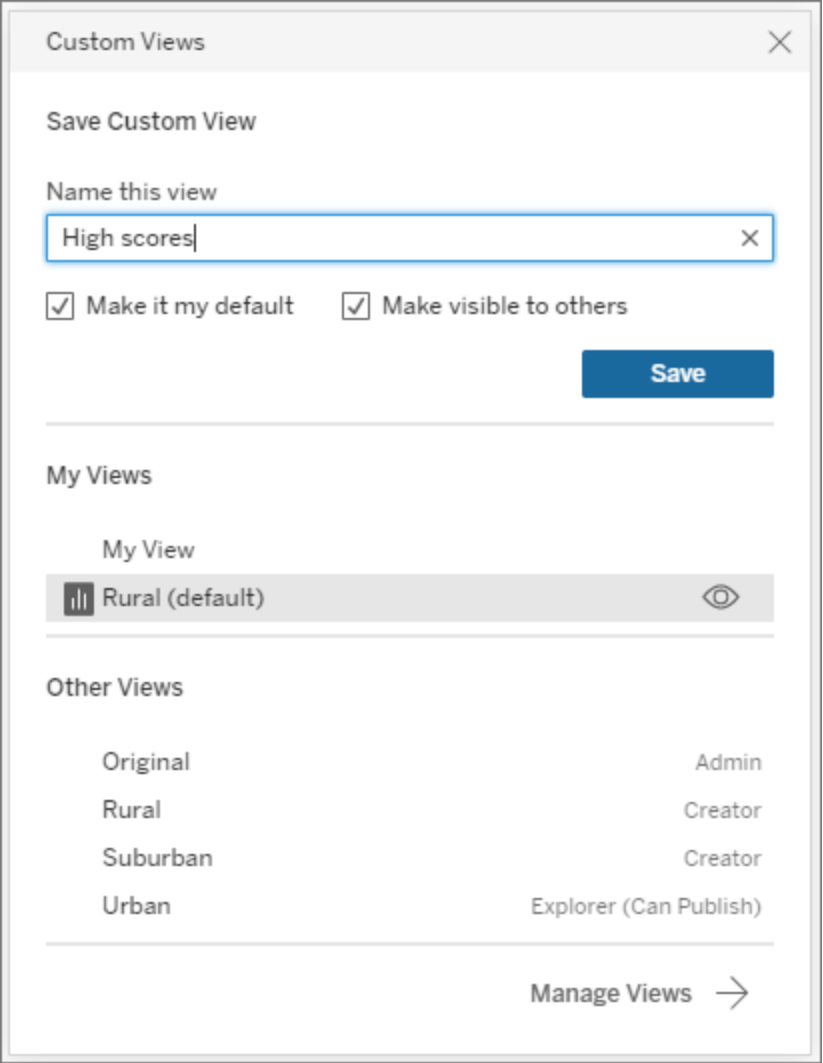

Find a custom view

From a view

When you're looking at a viz, you can change to a different custom view by selecting the View icon in the toolbar.

Any custom views you've made, and all visible custom views made by other users, appear in the list.

From the workbook

When you're looking at content at the workbook level, use the **Custom Views** tab to see all the available custom views for that workbook.

	↑ Name	Actions	Original view	Owner
<input type="checkbox"/>	ESL	...	Right vs Full Score	 Viewer
<input type="checkbox"/>	My View	...	Right vs Full Score	 Admin
<input type="checkbox"/>	Rural	...	Right vs Full Score	 Creator
<input type="checkbox"/>	Rural	...	Right vs Full Score	 Admin
<input type="checkbox"/>	Suburban	...	Right vs Full Score	 Creator

Set a default custom view

After you've found or made a custom view, you make it the default you see when you open that viz.

- 1. Select the **View** icon in the toolbar.
- 2. Check the **Make it my default** option.
- 3. Save.

The next time you open that viz, you'll land on that custom view.

Share a custom view

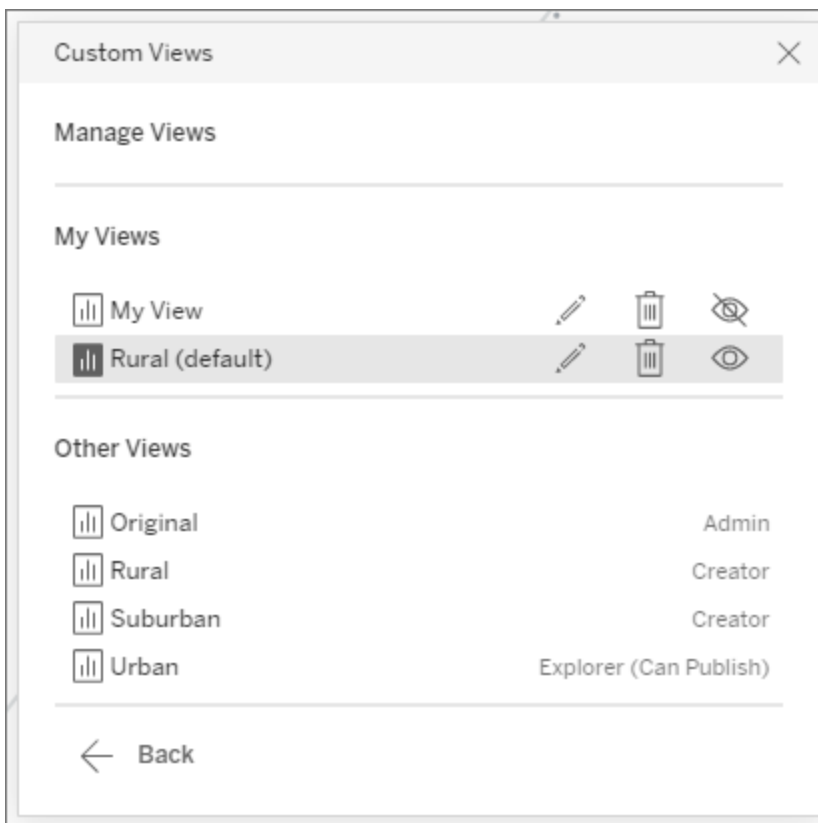

By default, custom views are private and only appear for the user who created them.

Note: Users with a Viewer site role can't make custom views visible to others. However, they can share a custom view by copying and sharing the URL.

Users with a site role of Explorer or higher can set a custom view as visible to others. This setting allows anyone with access to the original content to see the custom view.

To change an existing private custom view to be visible to others (or to make a visible view private):

1. Select the **View** icon in the toolbar.
2. Select **Manage Views**.
3. Toggle the eye icon to the desired state.
4. Close the dialog to save.

The eye with a slash  indicates the view is private to you. The eye  indicates the view is visible to others.

Delete a custom view

To delete a custom view:

1. Select the **View** icon in the toolbar.
2. Select **Manage Views**.
3. Select the trash icon.
4. Confirm that you want to delete the view.

Take care when deleting

If you're the owner of a custom view that's visible to others, remember it's deleted for everyone if you delete it.

Deleting a custom view also deletes any subscriptions based on that custom view.

Manage custom views

Administrators can change ownership for custom views and delete custom views created by other users.

Custom views can be managed for a piece of content or for a specific user.

1. Go to the Custom Views tab for the workbook or user.
2. Use the action menu to change the owner or delete the custom view.

<input type="checkbox"/>	Suburban	...	Right vs Full Score	 Creator

Tip: It's a best practice to change ownership of any custom views belonging to a user before removing them from the site. Deleting a user also deletes their custom views, including public views others may be using.

Safely change content with custom views

If you need to modify a view that has custom views (or the data source the view is built on), be aware that certain changes can break custom views. For more information, see [Maintain Content with Custom Views](#).

Publish Views to Salesforce

Bring your views from Tableau Cloud or Tableau Server right to your Salesforce ecosystem by publishing views to a CRM Analytics app or Salesforce Lightning page.

For more information, see [Publish Tableau Content to CRM Analytics](#) in Salesforce Help.

Prerequisites

See a complete list of [prerequisites](#) in Salesforce Help, including required licenses, account setup, and permissions.

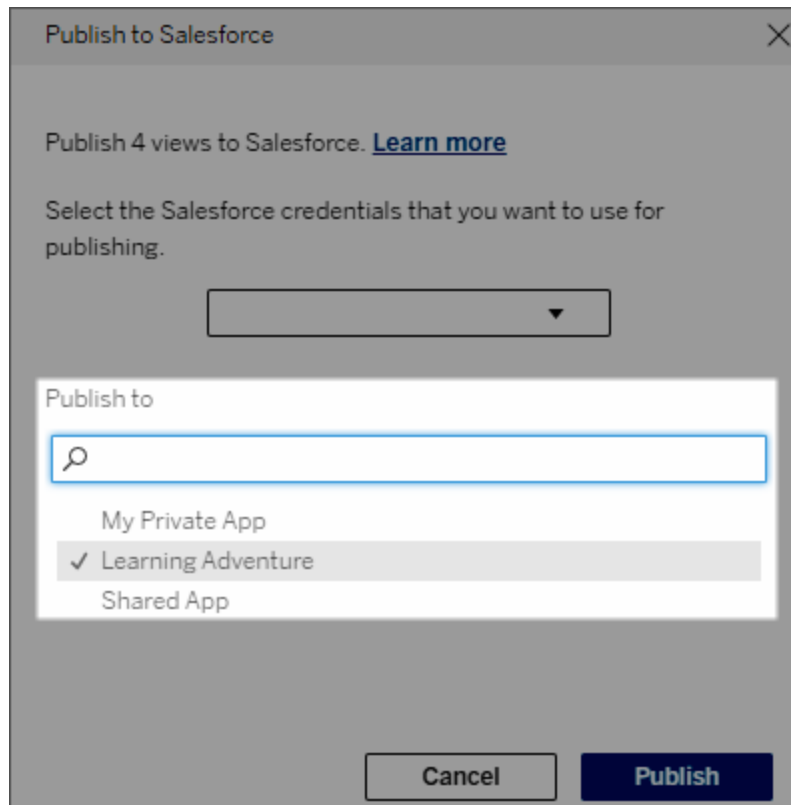

Publish a view to Salesforce

Select one or more views, including dashboards, sheets, and stories. Then, choose a destination from a list of CRM Analytics apps that you have access to edit or manage.

1. Select the view that you want to publish to Salesforce.

Note: You can select a maximum of 25 views at a time to publish to Salesforce.

2. For **Actions**, select **Publish to Salesforce**.
3. Select the Salesforce credentials that you want to use for publishing.
4. Select the destination app that you want to publish to. You can only see apps that you can edit or manage with the signed-in Salesforce user.

5. Click **Publish**.

Who can see the published view in Salesforce?

When you publish a view to Salesforce, anyone with access to the selected CRM Analytics app or Lightning page can see that the content exists. However, only those signed in with existing Tableau permissions can see the view.

Tableau View Lightning Web Component Seamless Authentication

Salesforce customers can now drag and drop embedded views from Tableau Cloud or Tableau Server into Salesforce Lightning pages without having to authenticate manually. Tableau View Lightning web component (LWC) seamless authentication allows you to view Tableau content using connected app trusted tokens without signing in.

Configure Salesforce settings

The following steps only need to be completed one time by a Salesforce admin:

1. From your Salesforce app, select the gear in the top-right corner, and then select **Setup**.
2. On the left navigation pane, enter "Tableau" in the **Quick Find** search bar.
3. Select the **Tableau Embedding** settings page.
4. Select the checkboxes for **Turn on Tableau View Lightning Web Component** and **Turn on token-based single sign-on authentication**.
5. For **Select Tableau User Identity field**, set an org-level user field to authenticate the user in Tableau. You must select the Salesforce user field that corresponds with the Tableau username. The dropdown shows the field value for the current user, or null if no value is defined. If none of the user fields match the Tableau username, select an empty field (for example, Federation ID or a custom field). Then, populate the empty field with the Tableau username for your users.

Note: The Tableau User Identity field setting applies to all users and doesn't need to be set on an individual basis.

6. Save your changes.
7. Experience Cloud only: Set up your Tableau site name and URL as a Content Security Policy (CSP) trusted site. For more information, see [Manage CSP Trusted Sites](#) in Salesforce Help.
8. If you are the Tableau admin, keep the Salesforce settings **Tableau Embedding** tab open while you configure Tableau settings in the next section. If you aren't the admin, share the **Issue URL** and **JWKS URI** with your Tableau admin.

Configure Tableau Settings

In one tab, open the Tableau Embedding settings page in your Salesforce org. In another tab, go to your Tableau site and follow these instructions to set up the Connected App.

For Tableau Server, follow these steps:

1. As a Tableau Server admin, sign in to the Tableau Services Manager (TSM) web interface.

2. Navigate to **User Identity & Access**, and then select the **Authorization Server** tab.
3. Select the checkbox for **Enable OAuth access for embedded content**.
4. Enter the **Issue URL** and **JWKS URI**, which you can find on the Salesforce org Tableau Embedding settings page. Use the **Copy** button on the Salesforce org settings page to copy the Issuer URL value, and then paste it into the TSM web interface. Repeat this process for the JWKS URI value.

Note: The JWKS URI field is marked as optional in the TSM web interface, however this value is required to use Tableau LWC seamless authentication.

5. Select **Save Pending Changes**.
6. Select **Pending Changes** in the upper-right corner of the page, and then select **Apply Changes and Restart** to stop and restart Tableau Server.

For more information, see [Register your EAS with Tableau Server](#).

For Tableau Cloud, follow these steps:

1. Open the Tableau **Settings** page, and then choose the **Connected Apps** tab.
2. From the New Connected App dropdown, select **OAuth 2.0 Trust**.
3. On the Create Connected App dialog, enter the **Issue URL** and **JWKS URI**, which you can find on the Salesforce org Tableau View Embedding settings page. Use the **Copy** button on the Salesforce org settings page to copy the Issuer URL value, and then paste it into the Tableau settings page. Repeat this process for the JWKS URI value.

Important: The Create Connected App dialog notes the JWKS URI field as optional, however this value is required to use Tableau LWC seamless authentication.

4. Select the checkbox for **Enable connected app**.
5. Select **Create**.

Note: The Connected App is named External Authorization Server.

For more information, see [Register your EAS with Tableau Cloud](#).

Use Tableau View LWC with seamless authentication

Now that the setup is complete, follow these steps to use Tableau View LWC with seamless authentication.

1. On the left navigation pane of your Salesforce org, enter “Lightning App Builder” in the **Quick Find** search bar.
2. Select **New** and follow the dialog prompts to create a Home, App, or Record page.
3. In the Components list, search for “Tableau” and drag and drop the **Tableau View** component onto the page.
4. Open a new tab and find the Tableau view that you want to embed. Select **Share**, and then select **Copy Link**.

Note: The URL must be for a view, not a workbook.

5. Return to the new Lightning page. In the Tableau View properties pane on the right, paste the Copy Link into the **URL for the Tableau view** field.
6. Select the checkbox for **Default Authentication Token**.
7. For Tableau Cloud, switch back to the tab with the Tableau view Share dialog, and then select **Copy Site ID**. Then, return to the new Lightning page. In the Tableau View properties pane, paste the Site ID into the **Site ID** field.
For Tableau Server, leave the **Site ID** field blank.
8. Optional fields:
 - Custom Authentication Token: Used to test a one-time-use JWT token. After testing, you must use a dynamically-generated JWT.
 - Show Tabs: Check this box to show the other tabs in a workbook.
 - Show Toolbar: Allows the user to interact with the toolbar to undo, redo, share, or export.
 - Custom Query Parameters: Use this field to filter the workbook.
 - Debug Mode: When checked, logs are printed to the console for troubleshooting.
 - Force refresh toggle: If you change the Tableau configuration, you can check this box to toggle a refresh for the Tableau view.
9. Select **Save**. You can now preview or publish your updates.

Embed multiple Tableau views

You can embed more than one Tableau view on a Salesforce Lightning page as long as all views come from the same site. Tableau only supports a single session, and that session is specific to the site. The most recently-granted session will wipe out the previous one.

To embed Tableau views from multiple sites, you must create a separate Lightning page that is site-specific.

Tableau View LWC seamless authentication on Mobile

Consider the following best practices to prevent issues for mobile users:

- Lightning page type: Mobile users can access App Pages and Record Pages, but not Home Pages.

Note: Record Pages must be associated with a specific type of record.

- If you use the same page for both desktop and mobile users, select **Activation** to verify that the Lightning page is set as the Org Default for both desktop and phone form factors.
- Consider creating separate Lightning pages for desktop and mobile to provide a tailored visual experience. The height for the Tableau View component is fixed and won't dynamically adjust to different screen sizes.
- To add a scroll bar to a view, select **Show Toolbar** from the Tableau View component properties pane.
- For the App Page type, select **Activation**, and then select the **Lightning Experience** tab. Add your page to the LightningBolt list to make the page easier to find on mobile.
- On mobile, iOS blocks cross-site traffic by default. Open your mobile settings, select Salesforce settings, and then turn on **Allow Cross-Website Tracking**. For more information, see [Enable cross-website tracking](#).

Troubleshooting Tableau View LWC seamless authentication

Verify the Salesforce and Tableau configuration

Verify that the **Issuer URL** and **JWKS URI** values match in both Salesforce and Tableau Settings and that JWKS URI ends with **id/keys**.

- For Tableau Cloud, open the Salesforce Settings Tableau Embedding page in one tab. In another tab, open the Tableau Settings Connected Apps tab. On the Connected Apps tab, select **External Authorization Server**, and then select **Edit**. Verify that the **Issuer URL** and **JWKS URI** values match and that the JWKS URI ends with **id/keys**.
- For Tableau Server, open the Salesforce Settings Tableau Embedding page in one tab. Then, sign in to the Tableau Services Manager (TSM) web interface, navigate to **User Identity & Access**, and then open the **Authorization Server** tab.

Verify the component in your Salesforce org

From the page that contains the Tableau view Lightning web component, select the gear icon, and then select **Edit Page**.

1. Confirm that the **URL for the Tableau view** field contains a valid URL for a Tableau view (not a workbook). Open the **Share** dialog for a Tableau view, and then choose **Copy Link**.
2. The checkbox for **Default Authentication Token** must be selected.
3. Verify the Site ID field:
 - For Tableau Cloud, the field must be populated with the Site ID copied from the embedded Tableau view Share dialog.
 - For Tableau Server, the field must be blank.

Verify the JWT token

Select Debug Mode to verify that the JWT token is working as expected.

1. Open the console logs and copy the token.
2. Go to the jwt.io website and paste the token into the **Encoded** field.
3. Verify the following:
 - The subject ("sub") matches the Tableau username.
 - For Tableau Cloud, the audience ("aud") is "tableau+SiteID". The scope ("scp") is accurate for what you want to do (for example, "tableau:views:embed"). For Tableau Server, the audience ("aud") is "tableau".

- The scope (“scp”) is accurate for what you want to do (for example, “tableau-views:embed”).
- The issuer (“iss”) EAS server is accurate.

Verify page activation

Sometimes, a user creates a Lightning page, but it hasn’t been activated or assigned anywhere, so users can’t find it. Select **Activation** to verify that the Lightning page is set as the Org Default for the intended form factors.

Tip:When debugging, it’s helpful to drag and drop a Rich Text component onto your page and add a brief description of the page type and the view URL that you’re trying to embed. This allows you to be sure that the page being viewed by the end user is the page that the admin is editing.

Confirm that Tableau View LWC is working without seamless authentication

1. From the Tableau View pane on your Lightning page, clear the checkbox for **Default Authentication Token**.
2. Open a new browser using a guest browser to avoid issues with cookies (for example, Firefox Private or Chrome Guest).

Note: Chrome Incognito will not work for this test.

3. Sign in to your Salesforce org on the guest browser. Select **Sign in to Tableau**, and then enter your Tableau credentials. Once signed in, the Tableau view should load.

Note: If the view doesn’t load, this indicates a broader issue beyond seamless authentication.

4. Select the checkbox for **Default Authentication Token**.
5. Select **Save**, and then close the guest browser window.
6. Open a new guest browser window and sign in to your Salesforce org again. The embedded Tableau view should now appear automatically using seamless authentication.

Error: LWC component version no longer supported

To resolve this error, follow these steps:

1. In the Components list, search for “Tableau”, and then drag and drop a new **Tableau View** component onto the page.
2. Copy all properties from the Tableau View pane for the old component over to the new component.
3. Select the delete icon on the old component.

Interact with Data in Tableau

This tutorial walks you through some of the basics of viewing and interacting with data visualizations, or views, in Tableau Server.

Tableau is a tool that lets you interact with published visualizations to explore insights, ask questions, and stay on top of your data. Here’s how to get started.

Go ahead. It’s safe to click around

Tableau is built for interaction. What you do to a visualization changes how it looks for you, just for now.

Others will still see the visualization as it originally appeared. And the data used to build it stays the same, too.

1: What is a Tableau Site?

A Tableau Site is a place for your team to share data and data visualizations with each other. You can explore what they’ve published and made available to you.

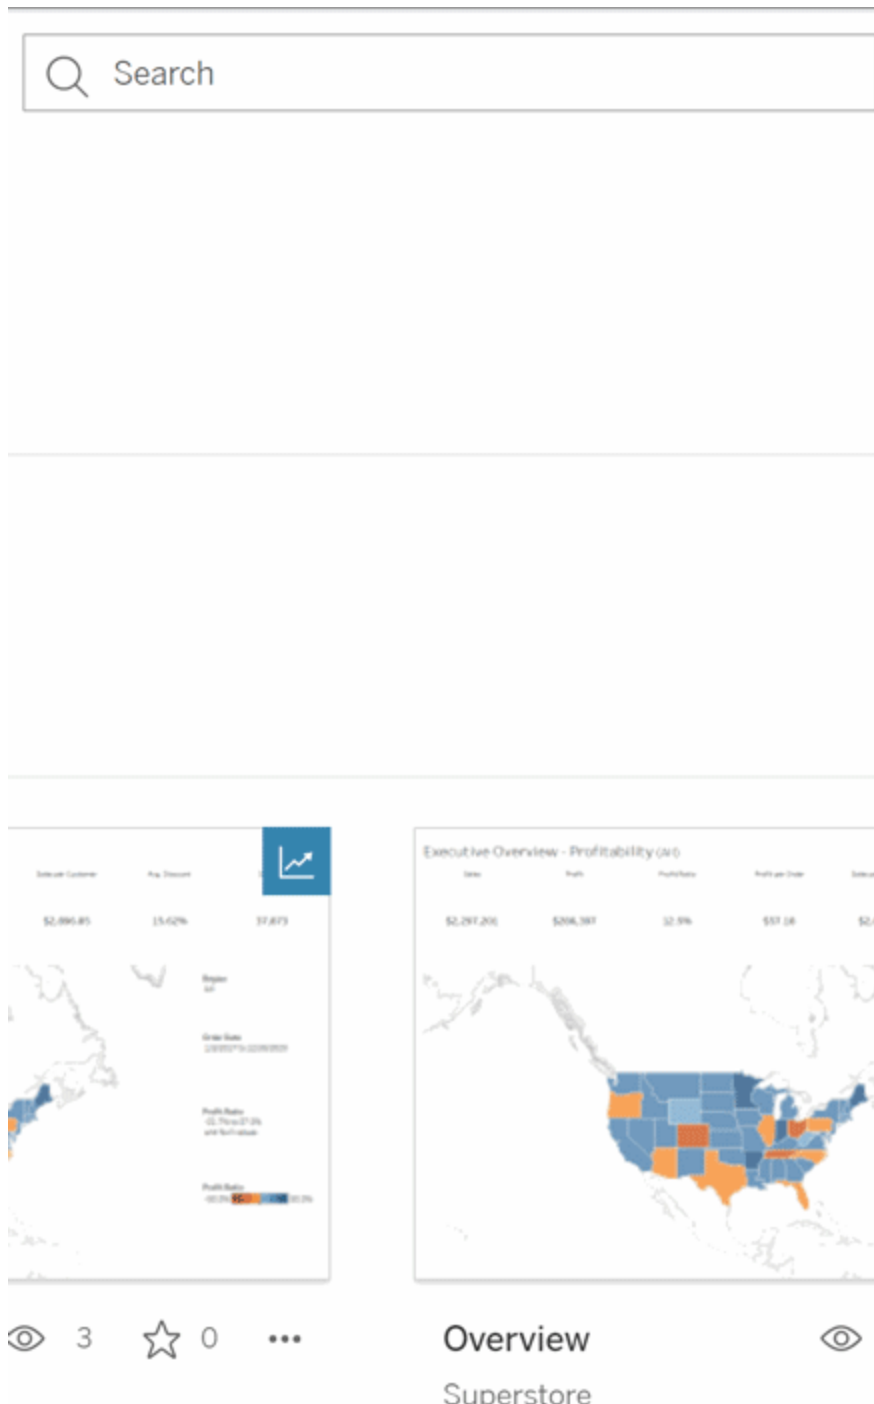

When you sign in to your Tableau site, you’ll land on the home page.

2: Search for a viz

Tableau calls visualizations on a site Views. Use search to find views or workbooks (a package of views in a single file).

Search results will show all the different content types relevant to your query.

You can select See All for all search results if the views in the quick search aren't what you were looking for, or use the Explore page to browse. There you'll see all the different types of content a Tableau site can host.

3: Interact with Content

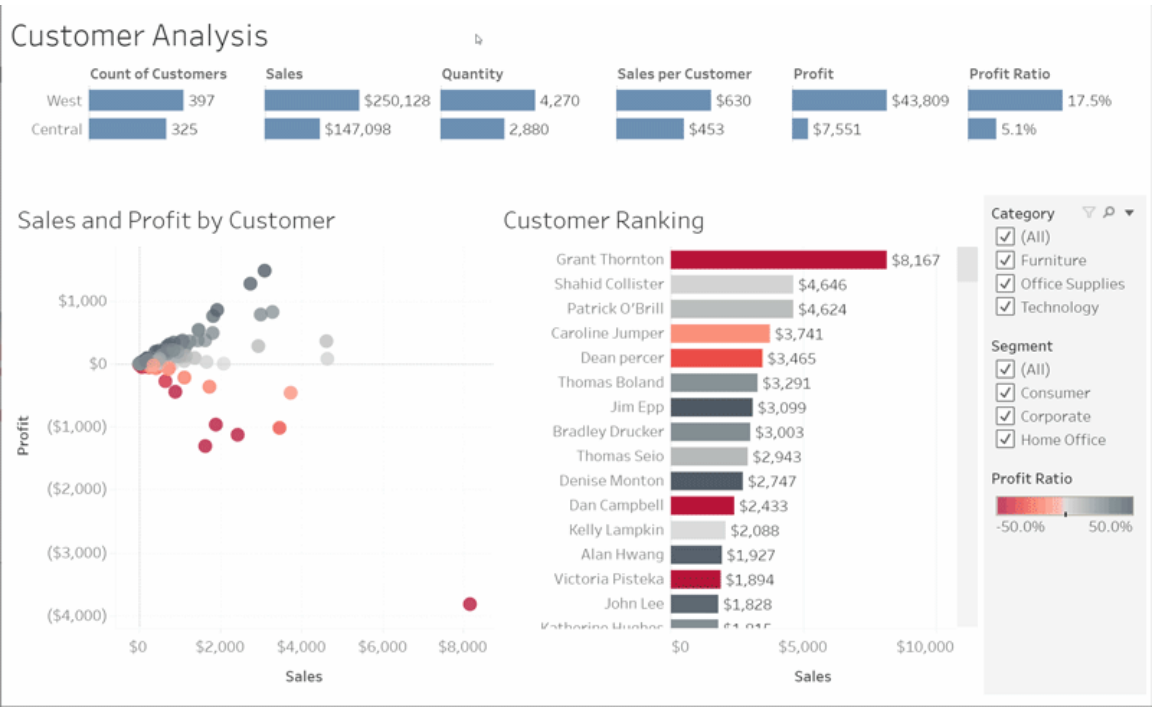

A published view is a canvas for you to interact and understand your data. Remember, you won't hurt or change the underlying data, or change what others see.

Here are some of the tools in your toolbox to find data insights.

See Details and Sort Data

Now that you know you can click on the data, let's check it out.

As you move the mouse across a view, you might see tooltips that reveal details about each data point, or mark. You can also select multiple marks.

Sort tables alphabetically or numerically by hovering over a column header and clicking the sort icon.

Filter Data

Trim or limit the visible data to a specific area, date, or category.

Undo/Revert

Maybe you didn't mean to exclude everything but one area. Click Undo to remove the last change, or use Revert to undo all your selections.

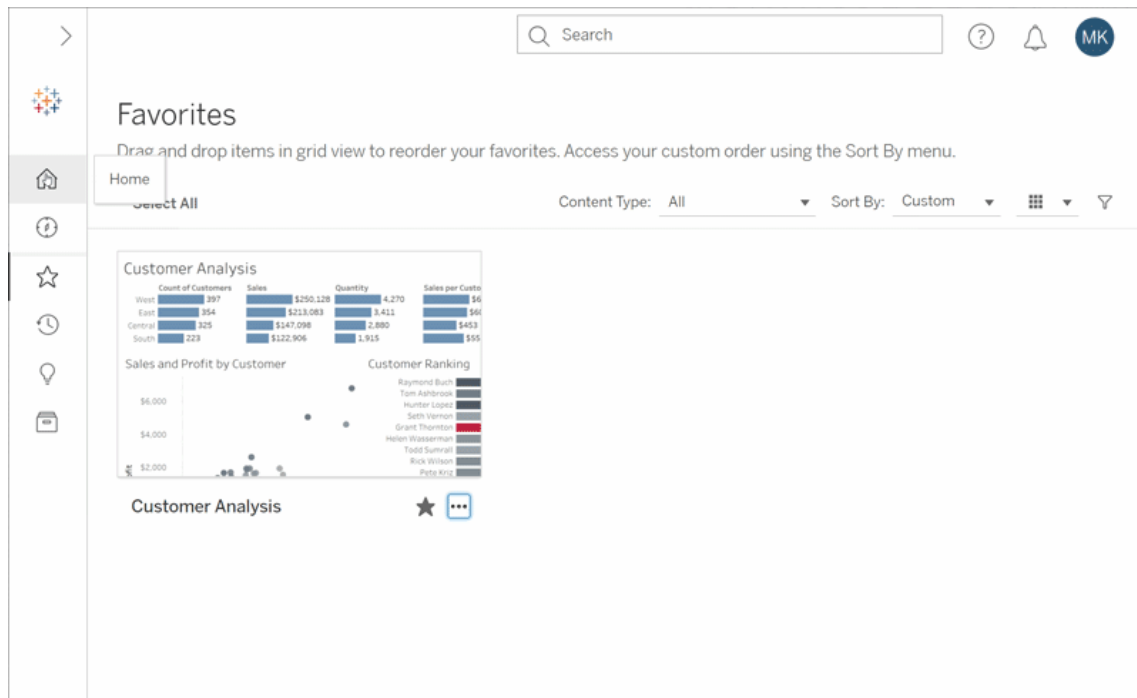

4: Keep up

This view can automatically update with new data, so you don't need to go searching for new charts to get the latest information. Keep it handy by clicking the star icon to add it to your favorites.

All favorites are added to the Favorites page in the navigation panel. And any recent dashboard or view you explored also appears in the Home page, waiting for you next time.

There's a lot you can do in Tableau Server, and this just explored some of the basics. For more information, see [What Can I Do with a Tableau Web View?](#)

Happy exploring!

Select Background Maps

Tableau comes with a set of online and offline background maps that you can access to create map views.

By default, Tableau connects to an online map provider.

The three background maps that come with Tableau are described below. They can be found in the **Maps > Background Maps** menu. If the workbook author has added a WMS server or Mapbox map to the workbook, they will be listed using the name the author gave them in the **Maps > Background Maps** menu as well.

None Displays data between latitude and longitude axes.

- Offline** This background map stores the images that make up the map in a cache on your machine for improved performance and offline access. For more information, see the offline maps section [below](#).
- Tableau** Connects to the Tableau background map. By default, all map views connect to this background map, unless you specify otherwise.

To select a new background map:

- In Tableau Desktop, Tableau Server, or Tableau Cloud, select **Map > Background Maps** and then select the background map you want to use.

Note: In Tableau Server, your administrator can restrict you to using only Offline maps. The specific server commands to configure this behavior can be found [here](#).

Set a default background map in Tableau Desktop

By default, all map views connect to the Tableau background map. In Tableau Desktop, if you do not want maps views to automatically be created with the Tableau background map, you can specify a different background map as the default.

To specify a default background map:

1. In Tableau Desktop, select **Map > Background Maps**, and then select the background map that you want to make the default.
2. Select **Map > Background Maps > Set as Default** to set the selected background map to the default.

The background map is automatically saved as a Tableau Map Source (.tms) and placed in the Mapsources folder of your My Tableau Repository. It is now the default background map for all new worksheets.

Use the Offline background map in Tableau Desktop, Tableau Cloud, or Tableau Server

You can create and inspect data in a map view offline using the offline background map that comes with Tableau Desktop.

To use the offline background map:

- In Tableau, select **Map > Background Maps > Offline**

Note: The offline background map uses map images stored on your machine. You can find these images in the following locations:

- On Windows: `C:\Program Files\Tableau\<Tableau Version>\Local\Maps`
- On Mac: `//Applications/<Tableau Version>.app/Contents/install/local/maps`

There are several actions, however, that require Tableau to retrieve a map image that may not be stored. If the new map image is not stored on your machine, you won't be able to load the map until you reconnect to the online map that comes with Tableau.

You may need to reconnect to the online map if you would like to do one or more of the following:

- **Turn layers on or off** - if you decide to turn on a layer that isn't stored in the cache, Tableau will need to connect to retrieve the necessary information.
- **Zoom in or out** - zooming in or out on a map requires different map images. If the images at the specified zoom level don't exist in the cache, Tableau will need to retrieve the updated maps.
- **Pan** - panning sometimes requires new map images. If you are working offline and don't have the necessary map images and legends stored in the cache, the new images and legends will not load.

To reconnect to the Tableau map:

- On Tableau Desktop, select **Map > Background Maps > Tableau**

Note: If you set a map to Offline and then publish the workbook, the published workbook will still use the Offline, stored maps, with all of the functionality and limitations of Offline maps noted above.

About the Tableau background map

The Tableau background map includes updated map and demographic data, as well as stylistic improvements. It has taken the place of the Tableau classic background map. Any map view created with an earlier version of Tableau Desktop, and with a connection to the Tableau classic background map, will automatically connect to the Tableau background map when opened in Tableau Desktop version 9.0 or later.

Note: If you create a map view with data layers in Tableau Desktop version 8.3 or earlier using the Tableau classic background map, and then open that view in Tableau Desktop 9.0 or later, the color of the data layers may appear differently due to data layering and color ramp (color palette) improvements made to the Tableau background map.

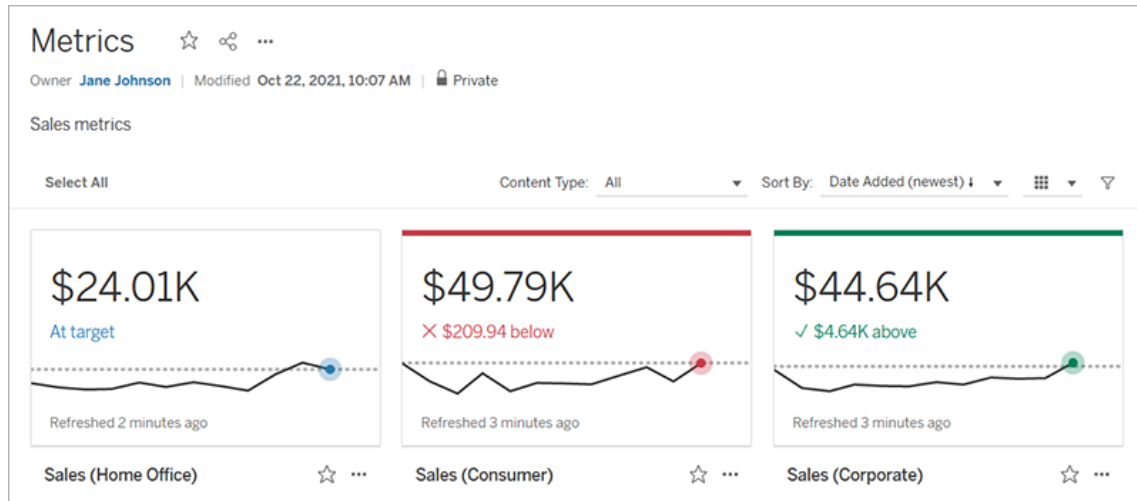

Create and Troubleshoot Metrics

Important changes coming for Ask Data and Metrics

Tableau's Ask Data and Metrics features will be retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau GPT and Tableau Pulse are reimagining the data experience](#).

In October 2023, Tableau retired the ability to embed metrics in Tableau Cloud and Tableau Server version 2023.3, in advance of the retirement of the Metrics feature

Metrics provide a fast way to stay informed about your data. Because metrics update automatically and display their current value in the grid and list view of your content, you can check all the key numbers you care about in seconds.

At their most basic level, metrics show the value of an aggregate measure, like the sum of sales. More complex metrics can include timelines, comparisons, and statuses that provide an easy to understand indicator of how you're performing relative to a prior point in time or a value you have defined.

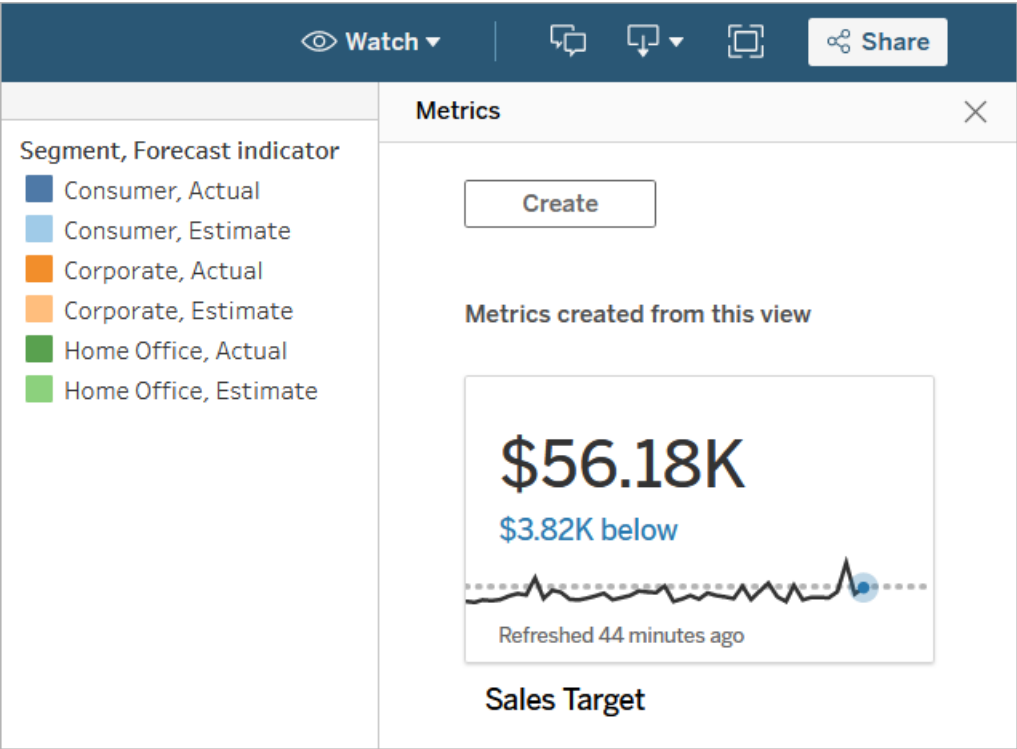

If you have a set of dashboards that you regularly check, create metrics for the numbers that you want to monitor, then track them in one place by adding them to your favorites or a collection, or by creating them in the same project. That way, you don't need to load and filter the dashboards unless you want to dig deeper into your data.

Find metrics on your site

There are a few ways to find metrics on your Tableau site. To browse all the metrics that you have permission to view, navigate to the Explore page, then select **All Metrics** from the content type menu.

If you're looking for metrics related to a particular view or workbook, check the connected metrics for that content. To see connected metrics for a view, open the view, then click **Watch >**

Metrics in the view toolbar. The metrics displayed are ordered from the newest creation date to the oldest.

To see connected metrics for all the views in a workbook, navigate to the workbook, then click the **Connected Metrics** tab. You can sort these metrics using the Sort By menu.

Components of a metric

The only data required to define a metric is an aggregate measure. Metrics are created from a mark in a view, and the measure associated with that mark defines the metric. The measure must be aggregated, because an unaggregated mark will not change over time. For information about dimensions and measures in Tableau, see [Dimensions and Measures, Blue and Green](#).

A metric can optionally be defined by a date dimension, and you can configure a comparison and a status for your metric. Each of these components will add context to the data presented on the metric card.

Metrics that have only a measure defining them will appear as a single number. This number will update when the data updates, but there will be no timeline on the card.

Timeline

When you select a mark to define a metric, if the mark has a date dimension associated with it, that dimension becomes part of the metric definition. Metrics with a date dimension show a timeline, and you can configure the historical comparison for the metric. By default, the historical comparison is to the previous mark.

When you open a metric's details page, the timeline shows the value of the measure based on the granularity of the date dimension, for example, daily sales or monthly users. Hover over the points on the timeline to see historical values.

Comparison

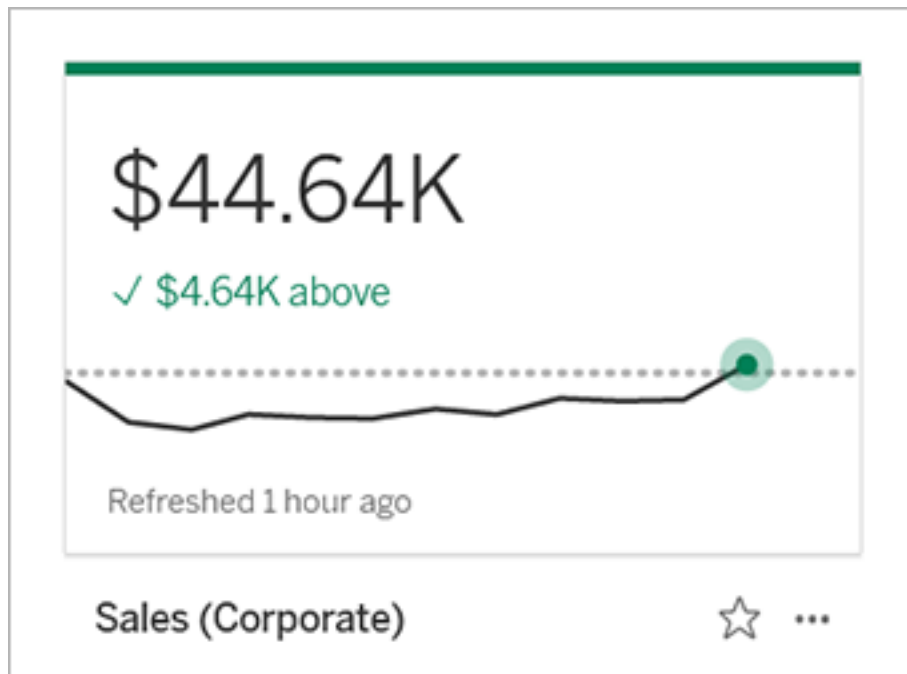

There are two types of comparisons that you can configure for metrics: historical comparisons and constant comparisons. You can configure a historical comparison only if a metric has a date dimension associated with it, but constant comparisons can be added for any type of metric.

A historical comparison is a relative comparison between the current value and a specified number of hours, days, or other unit of time previous. For example, you could set a comparison between the current value for monthly sales and the value from 12 months ago. Every

time data is added to a metric, the historical comparison will adjust relative to the date or time of the new data.

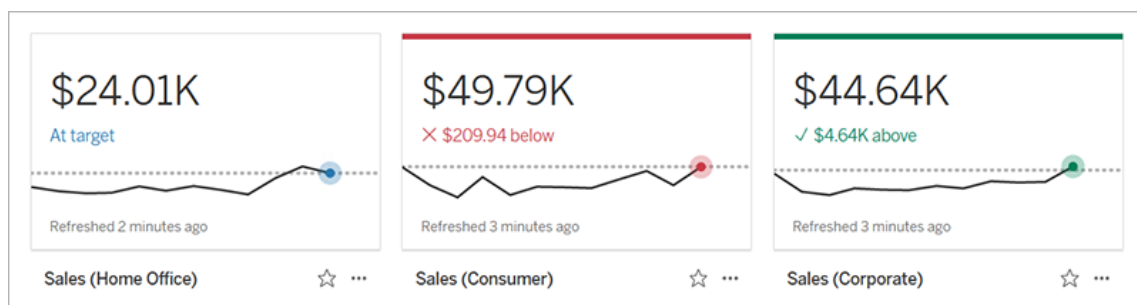

Constant comparisons are to a single value that doesn't change as new data is added. You might set a comparison to represent a threshold to stay above, for example, if you need to maintain a 90% on-time delivery rate. Or you might define a cumulative goal you are working toward, for example, a monthly sales target.

Status

For metrics with a constant comparison, you can define whether being above, below, or at the comparison value is good, bad, or neutral. A metric with a “good” status will display a check mark next to the comparison value, and the metric card will have a green band at the top. A metric with a “bad” status will display an X next to the comparison value, and the metric card will have a red band at the top. Metrics with a “neutral” status appear the same as metrics without a status indicator; there is no icon or color applied to the card.

Create a metric from a view

If you have a site role of Creator or Explorer (can publish), and you have the Create/Refresh Metric capability on the relevant workbook, you can create metrics on Tableau Cloud or Tableau Server.

Before you create a metric, check the connected metrics for the view to make sure that the metric you are planning to create doesn't already exist. Instead of creating a duplicate metric, open the existing metric and add it as a favorite.

Select the mark to define your metric

1. Navigate to the view that you want to create a metric from.
2. On the view toolbar, select **Watch > Metrics**.

The metrics pane opens.

3. If the pane shows connected metrics, select the **Create** button to enter authoring mode.
4. Select a mark. If you encounter an error, see When you can't create a metric.

The measure associated with this mark defines your metric. Any filters you apply to the mark are applied to your metric. If this mark has a date dimension associated with it, that date dimension also defines your metric, and your metric will display a timeline.

The metrics pane shows a preview of your metric. The value in the preview is the most recent value for the metric, which may differ from the value of the mark you selected if it was not the most recent in the time series. The preview updates as you try different configurations.

Describe and configure your metric

The options available to configure your metric depend on the mark you select and on the type of comparison you choose.

1. The **Name** field is pre-populated based on the mark you select. You can give the metric a different name. A metric must have a unique name within the project it belongs to.
2. Under **Description**, enter an optional message to help others understand your metric. For example, describe filters applied to the metric or indicate the data source used by the metric.
3. For the **Date Range** (only for metrics with a date dimension), select one of the default options, or set a custom range. If your metric has a large number of marks, limiting the date range can make it easier to read the timeline.
4. Select the **Comparison Type** for the metric: historical or constant.
5. For **Historical** comparisons:
 - Enter how far prior you want to compare against. The unit of time for the comparison is the same as the granularity of your data, such as hours or months.
 - Select **Show Comparison Line** to include a second line for the comparison period on the timeline.
6. For **Constant** comparisons:
 - Enter the value to compare against. Don't include commas or symbols in this field. To enter a percentage, simply type the number without the percent sign, for example, enter 25 instead of 0.25 for a target of 25%. When you enter a valid target value, the preview updates to show how far above or below the target the current value is.
 - Set the **Status** for the comparison to indicate whether being above, at, or below the value is good, bad, or neutral. By default, the status is set to neutral. Check the metric preview to see how different statuses affect your metric.
7. Under **Definition > Measure**, select the measure to use for your definition from the drop-down. This option appears only if the mark you select has more than one measure associated with it.

Finalize your metric

1. Under **Project**, select **Change Location** to choose a different project for the metric. By default, your metric will be added to the same project that the view belongs to.

Every metric in a project must have a unique name. Because a metric's name and project are initially set based on the mark you select, you might run into a conflict when you try to save your metric, if another user has already created a metric from that mark.

Either choose a different project or name for your metric or, if you want to overwrite the existing metric, see [Overwrite a metric](#).

2. Click the **Create** button.

A message appears with a link to the metric in the project you added it to.

3. Verify that the permissions for your metric are correct, following the guidance in [Set permissions](#).

By default, a metric inherits the permissions of the project it is created in. Anyone with access to your metric will be able to see the metric's data, even if they don't have permission to access the connected view or data source.

Now that you've created a metric, you can manage the metric the same way you manage other independent pieces of content on your Tableau site. Though metrics are created from a view, they exist independently of that view, unlike data driven alerts or subscriptions. You can

move the metric to a different project without moving the connected view. For information about managing content on your Tableau site, see [Manage Web Content](#).

Overwrite a metric

Once a metric is created, you can change the name, description, and configuration of the metric, but you can't change how the metric is defined. If you want to change the data that the metric uses, you must overwrite it. In order to overwrite a metric, you need to be the metric owner or be granted the correct permission capability.

1. To overwrite a metric, create a metric with the same name in the same project as the metric you want to overwrite.

The Overwrite Metric dialog appears.

2. Click the **Overwrite** button.

When you overwrite a metric, the metric continues to appear for those who have added it to their favorites, and any changes made to permissions for the previous metric will apply to the new metric.

When you can't create a metric

If you select a mark on a chart that doesn't support metrics, you'll get an error message explaining why you can't create a metric. The table below summarizes these scenarios.

Reason	Scenarios
You don't have the correct permissions.	<ul style="list-style-type: none">• The workbook owner or an administrator has denied the Create/Refresh Metric capability. For more information, see Permissions.
You can't access the complete data.	<ul style="list-style-type: none">• Row level security or user filters limit the data you can see. For more information, see Restrict Access at the Data Row Level.
The password for the workbook's data source is not embedded or is no longer	<ul style="list-style-type: none">• The workbook prompts for a password. For more information, see Set Credentials for Accessing Your Published Data.

Reason	Scenarios
valid.	
The data isn't at the correct level of granularity.	<ul style="list-style-type: none"> The data in the chart isn't aggregated. Metrics use aggregations, such as sum or average. For more information, see Data Aggregation in Tableau. There are multiple values per cell of data—a result of data blending. For more information, see Troubleshoot Data Blending.
The date dimension is not supported.	<ul style="list-style-type: none"> The chart includes both date parts and date values. For more information, see Change Date Levels. The date dimension uses the ISO 8601 calendar rather than the standard Gregorian calendar. For more information, see ISO-8601 Week-Based Calendar. The date dimension is aggregated at the custom level of Month / Year or Month / Day / Year. For more information, see Custom Dates.

Edit a metric's configuration

Starting in 2022.2, you can change the configuration for a metric. A metric's configuration includes the comparison, date range, and status indicator. The configuration options available depend on the type of metric. Metrics with a timeline allow you to set a historical comparison or a constant comparison. Single number metric support only a constant comparison.

A metric's configuration does not include the metric definition (the measure and date dimension that generate the metric value). If you want to change the definition, overwrite the metric with a new metric.

To edit a metric's configuration, you must have the overwrite capability for the metric.

1. Open the metric details page for the metric you want to edit.
2. Mouse over the configuration section. Click anywhere on the section to enter editing mode.

Metric Details

Owner
[Jane Johnson](#)

Description
No description available.

Configuration 

Date Range	Last 12 months
Comparison	1 month ago

3. For a timeline metric, set the date range to display on the metric card and details.
4. Select the comparison type. For a constant comparison, set a comparison value and status. For a historical comparison, set how far prior you want to compare against and choose whether to show a comparison line on the timeline.
5. Click **Save**. Your configuration changes will appear to anyone who views the metric.

How metrics refresh

When a metric refreshes, it checks the connected view (the view the metric was created from) for new data. A refresh doesn't necessarily update the value of a metric, because there may be no changes to the data.

Metrics refresh at a frequency either based on an extract's refresh schedule or, for live data, every 60 minutes. The time of the last refresh is displayed on the metric.

Fix failing refreshes

If a metric isn't able to access the connected view or its underlying data, the refresh will fail. If the refresh for your metric fails, you'll receive a notification, which notes the time of the failure and the affected metric.

Metric refreshes may fail for one of the following reasons.

- The connected view was deleted or modified.
- Permissions changed for the connected view.

- The password for the data source is no longer embedded or is no longer valid.
- The metric owner doesn't have the required site role to refresh the metric. A site role of Creator or Explorer (can publish) is required.
- There was a temporary connectivity issue, which will resolve itself.

To identify the cause of the failure, look at the metric details. Make sure that the metric owner has the required site role to refresh the metric. Then inspect the **Connected View**.

Metric Details

Owner
Jane Johnson

Connected View

The metric has been created from this view:

Weekly Sales and Profit

Definition

Measure	SUM(Profit)
Date Dimension	WEEK(Order Date)

If the connected view is still listed

Open the view to investigate the cause of the failure.

If the view loads, check that the measure and (optional) date dimension that define the metric are still present in the view.

- If the view appears to be unchanged, you might no longer have permission to refresh metrics from it. The content owner or a Tableau administrator can change the Create/Refresh Metric permission capability. For more information, see [Permissions](#).
- If the measure is no longer present, the view has been modified so the metric can't connect to the data needed to refresh. The content owner or a Tableau administrator can check the revision history and restore previous versions. For more information, see [View Revision History](#).

If the view doesn't load, but instead prompts for a password or displays an error when connecting to the data source, the password for the data source is not embedded or is no longer valid. The content owner or a Tableau administrator can edit the data source connection to embed the password. For more information, see [Edit Connections](#).

If there is no connected view listed

The view was deleted or you no longer have permission to access the view. Contact your Tableau administrator for assistance.

Resume suspended refreshes

If a refresh fails enough times, the refresh is suspended. You'll receive a notification if the refresh for your metric is suspended.

When a metric refresh is suspended, Tableau no longer attempts to get new data for the metric. Metrics with suspended refreshes continue to present historical data.

If the cause of the failure is fixed, you can resume the refresh.

1. Open the affected metric.
2. On the warning message, click **Resume refresh**.

Tableau attempts to perform the refresh. If this attempt succeeds, you'll receive a notification, and the refresh will resume on schedule. If the attempt doesn't succeed, your refresh remains suspended.

Try overwriting the metric if the connected view is still available. For more information, see [Overwrite a metric](#). Otherwise, you can keep the metric to reference past data or delete the metric.

Note: If the metric refresh is suspended because you don't have the required site role for it to refresh, you won't be able to resume the refresh or delete the metric.

Metrics appear in Tableau Catalog

Starting in 2019.3, Tableau Catalog is available with Data Management in Tableau Cloud and Tableau Server. When the Tableau Catalog is enabled in your environment, you can see metrics in the Catalog lineage tool, and metrics affected by data quality warnings display those warnings. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

When you have metrics defined for the numbers you want to monitor, it's important to know if the data that the metrics rely on are impacted in any way. You can use Catalog in a couple of ways to know this. First, data quality warnings set on the data your metric is based on show on the metric. These warnings appear when you open a metric in Tableau Mobile, and in Tableau Server and Tableau Cloud when you hover over a metric in grid view and on the metric details page, as shown below:

Tableau Server on Windows Help

For more information, see "Set a Data Quality Warning" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

You can also use the lineage tool in Tableau Catalog to see the upstream sources that your metric relies on. When doing an impact analysis, you can see which metrics are affected if a certain column or a table is changed or deprecated, or if certain workbooks are removed. Including metrics in the lineage means that Catalog gives a full picture of the impact changes can have on the assets in your environment.

For more information, see "Use Lineage for Impact Analysis" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

Set Credentials for Accessing Your Published Data

When you publish a workbook to Tableau Cloud or Tableau Server, you can publish the data source it connects to as part of the workbook (*embedded* into the workbook), or as a separate, standalone data source. In addition, if the data source you're publishing requires authentication, you can customize how credentials are obtained.

The type of authentication to your data source is independent of how people sign in to your Tableau Cloud or Tableau Server site. For example, to give people direct access to the data in a workbook, you would embed a database user's credentials into the data source's connection. But anyone viewing the workbook would still need to be able to sign in to the site on Tableau Cloud or Tableau Server to open your workbook.

This topic describes how to set authentication on data connections as part of the publishing process.

Note: This topic doesn't apply to connections to that don't require authentication, such as text files or Excel files.

Set the authentication type

For many types of connection you can embed a database user's name and password, or use single sign-on (SSO). Specific exceptions are described later in this topic.

The following steps describe how to set authentication as part of publishing a data source or workbook. You can do this for each connection in the data source.

1. In the Publish Workbook dialog box, go to the **Data Sources** area, which lists the workbook's connections, and select **Edit**.
2. In the **Manage Data Sources** popup, after you decide whether to publish the data source separately or as part of the workbook, select an authentication type for each connection in the data source. The available authentication types depend on the connection type, and they can include one or more of the following:
 - **Prompt user:** Users must enter their own database credentials to access the published data when the view or workbook loads.
 - **Embedded password:** The credentials you used to connect to the data will be saved with the connection and used by everyone who accesses the data source or workbook you publish.
 - **Server run as account:** A single Kerberos service account is used to authenticate the user. On Windows this is the account that Tableau Server runs as. On Linux it can be any Kerberos account.
 - **Viewer credentials:** The viewer's credentials are passed through to the database using SSO (usually Kerberos).
 - **Impersonate with embedded account or Impersonate with server Run As service account:** Impersonation using embedded credentials connects with the embedded credentials and then switches to the viewer's identity (only for databases that support this). Impersonation using the Run As service account is sim-

ilar but first, connects with the Kerberos service account before switching to the viewer's identity.

- **Refresh not enabled** or **Allow refresh access**: These options appear when you publish an extract of cloud data such as from Salesforce, and database credentials are needed to access the underlying data. **Allow refresh access** embeds the credentials in the connection, so that you can set up refreshes of that extract on a regular schedule.

Important: How you want to keep extracted data fresh is also a factor:

- If you want to set up an automatic refresh schedule, you must embed the password in the connection.
- If you're publishing a cloud data connection to Tableau Cloud, the publishing steps alert you if you must add Tableau Cloud to the data provider's authorized list.
- You can't publish an extract that's created from a Kerberos-delegated, row-level-secure data source.

Dropbox, OneDrive connections

For Dropbox and OneDrive, when you publish a data source or workbook and select **Embedded password**, Tableau creates a saved credential and embeds it in the data source or workbook.

Workbook connections to Tableau data sources

When you publish a workbook that connects to a Tableau Cloud or Tableau Server data source, rather than setting the credentials to access the underlying data, you set whether the workbook can access the published data source it connects to. Regardless of the original data type, the choice for server data sources is always **Embedded password** or **Prompt users**.

If you select to prompt users, a user who opens the workbook must have **View** and **Connect** permissions on the data source to see the data. If you select embed password, users can see the information in the workbook even if they don't have View or Connect permissions.

Virtual connections

As of Tableau Cloud and Tableau Server 2022.3 and Tableau Desktop 2022.4, when you publish Tableau content like a data source or workbook that uses a virtual connection and select **Embed password** or **Embed credentials**, the viewer of the content will have your permissions to connect to and query the virtual connection. However, any data policies associated with the virtual connection are always evaluated using the viewer's identity—not yours.

For example, you publish a workbook that uses a virtual connection. To let viewers of the workbook connect to and query data by way of the virtual connection, you embed your permissions to connect to and query the virtual connection. Then, any data policies associated with the virtual connection prevent the viewers of the workbook from accessing any sensitive data.

When evaluating whether the tables in a virtual connection can be viewed and accessed, the identity of the content creator is used. However, when evaluating any data policies associated with the tables in a virtual connection, the viewer's identity is used. And the content creator can only ever embed connect permissions to the virtual connection—not edit permissions.

If you choose not to embed permissions, then only users with permissions to access the workbook or data source and with connect permissions to the virtual connection can access the workbook or data source.

The embed password and embed credentials options for virtual connections don't work in Tableau Cloud 2022.2, Tableau Server 2022.1, and Tableau Desktop 2022.3 and earlier. If you select these options before you upgrade to 2022.3 (for Tableau Cloud and Tableau Server) or 2022.4 (for Tableau Desktop), the options will work as expected after you upgrade. Then, you're able to embed your permissions for querying a virtual connection.

Explore Dashboards with Data Guide

Have you ever discovered a new Tableau dashboard and wondered what data means or how to use it? Or, have you ever published a new dashboard and wished that you could include instructions about how to use your dashboard?

Data Guide provides helpful information about a dashboard and insights about the data behind it. Data Guide allows dashboard creators to provide more explanatory context for end users—like descriptions and links to resources—directly in the dashboard. And Data Guide automatically surfaces insights powered by [Explain Data](#) to help users find outliers and learn about explanations for a mark. Explain the Viz (powered by Explain Data) identifies outlier measures and potential key drivers behind them.

These contextually relevant details can help dashboard users navigate and use new dashboards more easily, allowing users to find insights faster, trust that they're looking at the right data, provide context for data, and establish confidence in their understanding of the viz.

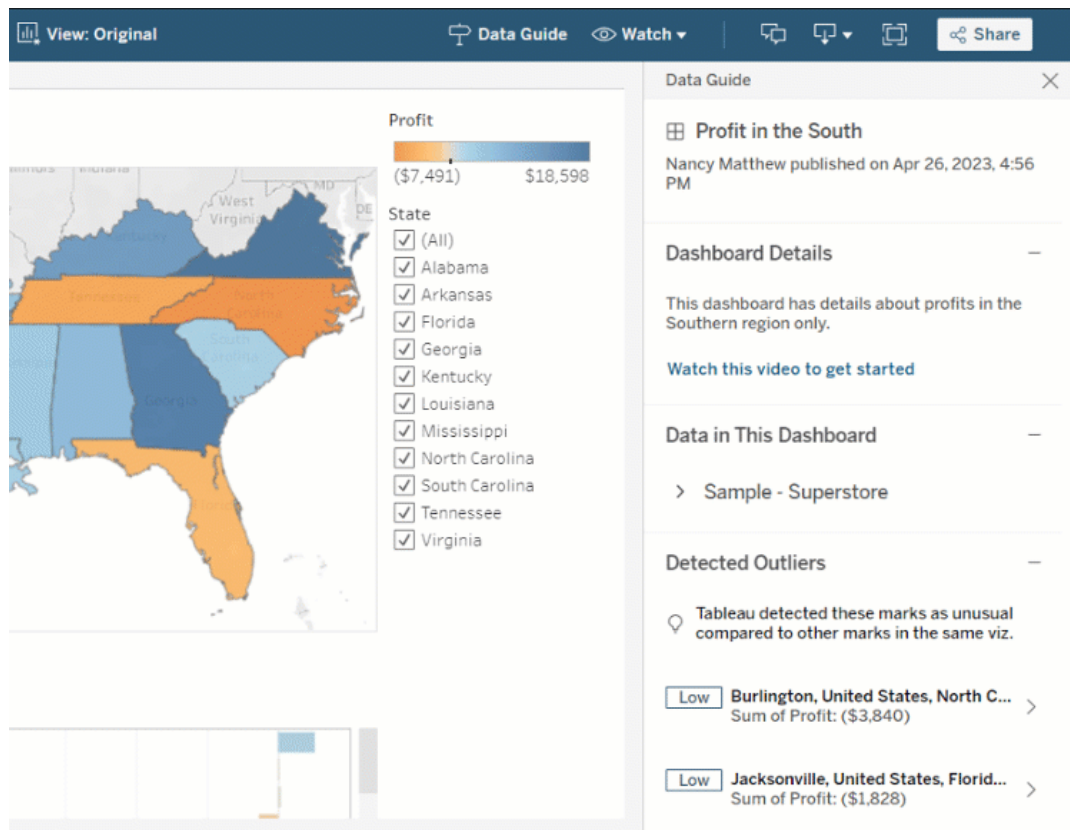

Customize Data Guide as an author

1. From your dashboard, choose the **Edit** button.
2. Choose **Data Guide** in the toolbar.
3. In the Data Guide pane, type a description to help your end users understand the purpose of your dashboard.
4. Select **Add link**, and enter a descriptive label for your link text and the URL.
5. Choose **OK**.
6. Select a viz (a sheet in the dashboard). Data Guide updates automatically so you can add a description and resources that are relevant to each viz in your dashboard.
7. Type a description, and add links relevant to the viz.
8. Choose **OK**.

Tip: To use Data Guide to write custom alt text to improve the accessibility of your vizzes, see [Show more text and make it helpful](#).

Explore Data Guide as a dashboard user

1. From the dashboard, choose **Data Guide** in the toolbar.
2. Read the description of the dashboard and explore resources provided by the dashboard author.
3. Expand **Data in This Dashboard** and **Detected Outliers** to learn more about the underlying data used in the dashboard.
4. Select a viz (an object in the dashboard).
5. Read the description of the viz and explore resources provided by the dashboard author.
6. Expand **Data Summary** and **Detected Outliers** to learn more about data in that viz.
7. Select a mark or multiple marks, such as a bar on a chart or a region on a map, to see information about **Data in This Mark** and **Applied Filters**. Select a single mark to see possible **Explanations** for its value.

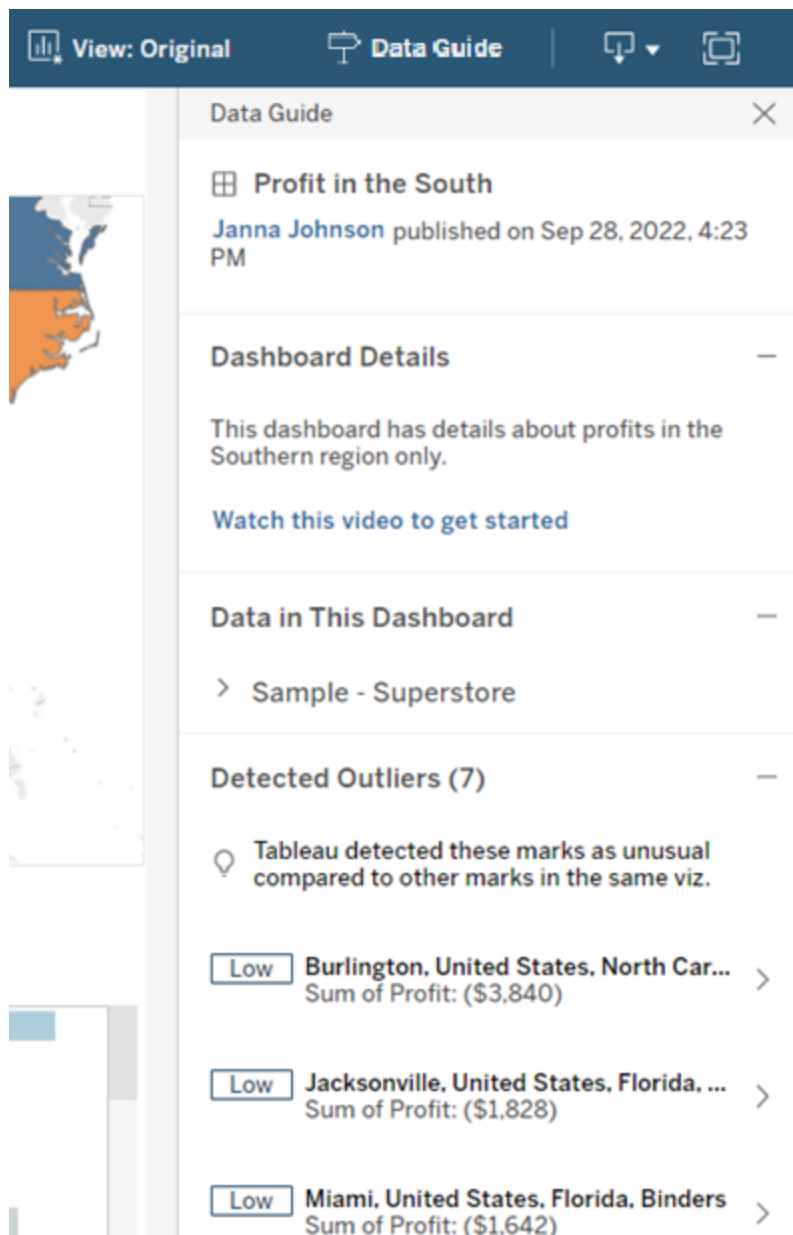

Explore Data Guide at different levels

By default, Data Guide is closed when you open a workbook. And you can open Data Guide in the toolbar. At the top of the Data Guide pane, you see the name of the dashboard or viz that you selected. As a dashboard author, you can write descriptions for both the dashboard and for individual vizzes that make up your dashboard.

Understand dashboard-level details

At the dashboard level, Data Guide:

- Displays the dashboard's name, author, and last published date.
- Can include a description written by the dashboard author and links to related resources, such as videos or wiki pages.
- Lists the data sources used by the dashboard and details about the data, such as which dimensions and measures are used.
- Reveals detected outliers in the dashboard that are identified by Explain Data. For more information, see [Get Started with Explain Data](#).

Understand viz-level details

When a user selects a specific viz (dashboard object), Data Guide:

- Displays the viz's name.
- Can include a description written by the dashboard author and links to related resources, such as videos or wiki pages.

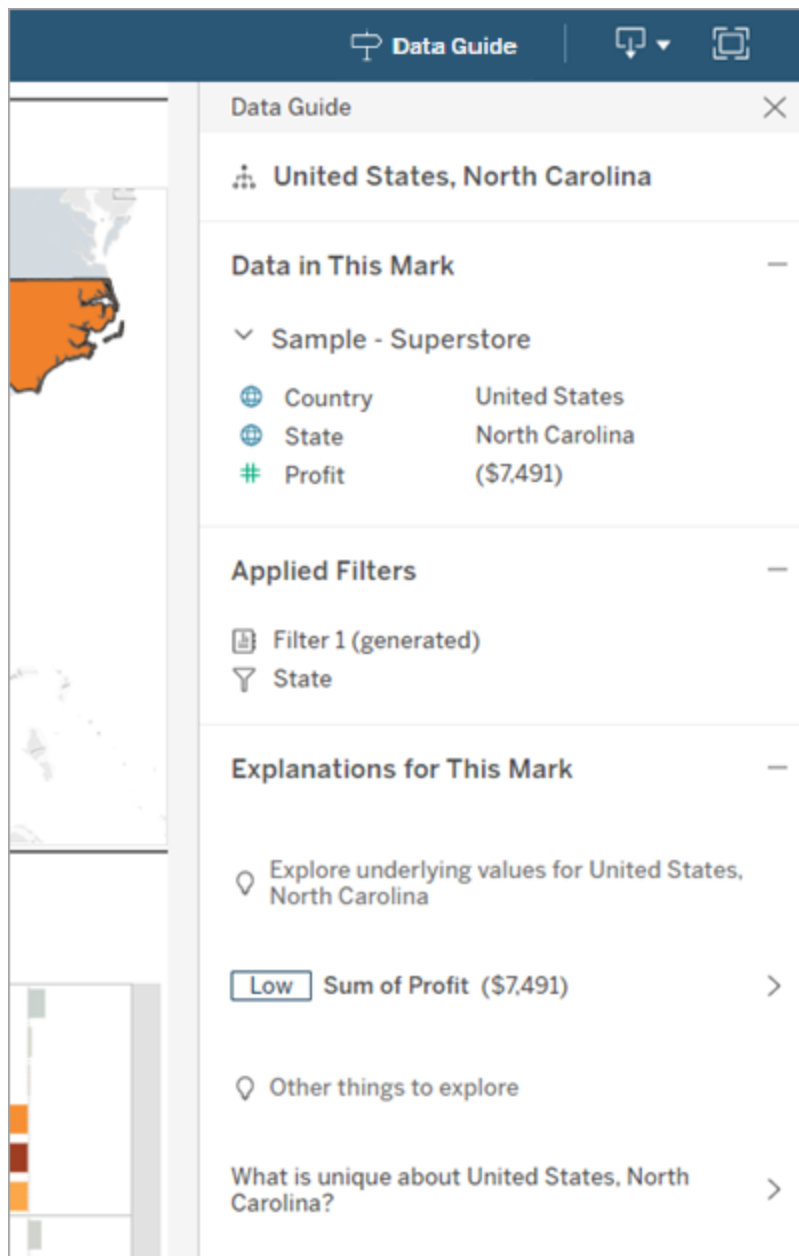

- Lists the data sources used by the dashboard, including the dimensions and measures used.
- Lists applied filters and data used in the viz, so you can identify how the data is being influenced by filters that users interact with.
- Has a summary of the data used in the viz, including the number of data points and sorting details.
- Reveals detected outliers in the viz that are identified by Explain Data. For more information, see [Get Started with Explain Data](#).

Understand mark-level details

When a user selects a mark (or marks) such as region on a map, Data Guide:

- Displays the name of the mark.
- Lists applied filters and data used in the viz, so you know what's included and what's excluded.
- Reveals detected outliers in the viz that are identified by Explain Data. For more information, see Get Started with Explain Data.

Control Data Guide visibility

By default, Data Guide is closed when you open a workbook. When you open or close Data Guide, it remains in this state for all workbooks on the site. A site administrator can hide Data Guide for all users. This removes the Data Guide button from the Tableau toolbar on all workbooks on the site. To hide Data Guide:

1. From the left pane, choose **Settings**.
2. From the **General** tab, scroll to **Availability of Data Guide**.
3. Choose **Hide**.
4. Choose **Save**.

Set a Data Freshness Policy for Query Caches and View Acceleration

Understand data freshness for Query Caches

You've built your workbook, and your team loves it. But sometimes people need to click the Refresh button for the most up-to-date data to appear in the viz. You built the workbook using a live connection, so why does the data need to be refreshed? The answer is performance.

To improve performance, Tableau caches the results of queries used to fetch data, so subsequent visits can reuse and return that cached data faster. You can click the Refresh button to retrieve updated data, but this can add to potential performance costs.

To balance data performance and freshness, set a data freshness policy for your workbook. When you set a data freshness policy, your data is refreshed at the time you specify. Tableau won't visualize cached data that doesn't meet the freshness policy you've set.

Understand data freshness for View Acceleration

With the View Acceleration feature, Tableau precomputes selected workbooks to generate views, resulting in significantly reduced load times. A precomputation schedule is created based on the data freshness policy or extract schedule that you set for the selected workbooks to provide data that is both performant and fresh.

To minimize resource consumption, the number of precomputation jobs that you can run is limited to 12 per day. For example, if your data freshness policy is set to less than two hours, the performance benefits of View Acceleration are limited to the first 12 refreshes in a day.

Choose what's best for your workbook

Some people might not want caching so that they always have the freshest data, while other people might want large caches to reduce overhead and improve workbook performance. The first step in setting a data freshness policy is to decide what's right for your business.

Tableau Cloud refreshes cached data every 12 hours by default, and workbook owners can set data freshness policies at the workbook level.

In Tableau Server, server administrators can [set a default caching policy for all sites on the server](#), and workbook owners can set data freshness policies at the workbook level.

Note: Data freshness policies aren't available in Tableau Desktop or for workbooks that use extract and file-based data sources.

Edit a workbook data freshness policy

To edit a workbook data freshness policy, you must be the workbook owner, and the workbook must have a live connection to the data source.

1. Sign in to a site on Tableau Cloud or Tableau Server.
2. From the Home or Explore page, navigate to the workbook you want to set a policy for.
3. Click the details icon .
4. From the Workbook Details dialog, click **Edit Data Freshness Policy**.
5. Choose one of the following options:
 - Site default (12 hours)
 - Always live (Tableau will always get the latest data)
 - Ensure data is fresh every
 - Ensure data is fresh at
6. Click **OK**.

Tableau Server on Windows Help

Select All Sort By: Sheet (first-last) ↑

Type	Name	Actions	Views (all-time)
<input type="checkbox"/> ☆	Regional Sales	...	26

Site default refreshes your data every 12 hours, which is a great option if your audience regularly uses your dashboard, but doesn't need up-to-the-minute data freshness.

Always live provides the freshest data at all times, which can increase loading time.

Ensure data is fresh every... allows you to specify how often data is refreshed with the granularity of minutes, hours, days, or weeks.

Ensure data is fresh at... allows you to schedule the time and day for data refreshes. If you have an important meeting every Monday, Wednesday, and Friday at 09:00 AM Pacific time, then you can set your data refresh to occur at 08:45 AM every Monday, Wednesday, and Friday, so you have the freshest data when your meeting starts.

Use Dynamic Axis Ranges

It's key that your users understand the range represented in a viz so that they can correctly analyze the data. Especially when analyzing multiple vizzes in a dashboard or multiple worksheets at the same time, it can be easy for users to misinterpret data when the range of the axes is different between vizzes. For example, when two bar charts appear next to each other, the bars in both charts might appear to be equivalent sizes. However, the axes might have very different ranges, making the charts misleading.

To help users understand the range of the axis, authors can use Dynamic Axis Ranges to set the minimum and maximum values of an axis range by using numeric parameters or date parameters. Then, as users navigate across vizzes, the axes update synchronously. This makes it easier for your users to analyze data across vizzes easily and accurately. And by limiting the range of the data, you can view a subset of data without filtering the underlying data or impacting the moving average of your data.

Dynamic Axis Ranges can also be used to extend or shorten the range of an axis without filtering out the underlying data. This is ideal for showing progress against a goal or showing a moving average.

Supported field types

Dynamic Axis Ranges support any parameter that is compatible with the selected continuous axis, for example:

- Numeric parameters
- Temporal parameters (date or dateTime)

Configure a dynamic axis range

1. From a Tableau sheet, [create a parameter](#) for your axis.
2. Right-click the axis, and choose **Edit Axis**.
3. For the Range, choose **Custom**. Then, select the parameter that you created for either the start or end axis extent.
4. Close the dialog box.

5. If you're using multiple sheets on a dashboard, repeat these steps for the axes across the different sheets.

Understand limitations and edge cases

Dynamic Axis Ranges aren't updated within **Stories**. If the parameter used for the axis is deleted, then the most recent parameter value remains as the axis extent. The next time you edit the axis, an error message will prompt you to choose a new parameter to be used.

Use Dynamic Axis Titles

Tableau's flexibility empowers authors to quickly analyze different data sets and visualize data differently for deeper analysis. But with that flexibility, comes the responsibility to communicate accurately the data that is used in a viz. For example, it's critical to communicate the units of measure that change based on a parameter value. Imagine that you're looking at a viz of the weather that shows a forecast of 25 degrees. In Fahrenheit, that forecast might be a great ski trip. But in Celsius, that forecast might call for a trip to the beach.

As an author, you can use Dynamic Axis Titles to update the axis title based on the value of a parameter or a single-value field (for example, an LOD calculation). If you use **swap parameters**, the axis titles update to match the data being used.

Supported field types

To be used as a Dynamic Axis Title, fields must be:

- A single-valued and a **fixed LOD calculation**
- A parameter
- A constant calculated field
- A top 1 set

Configure a dynamic axis title

1. From a Tableau sheet, drag a continuous field onto a shelf.
2. Double-click the axis to open the **Edit Axis** dialog.
3. Under the **Axis Titles** section, choose the field you want to use for your axis title from the list.
4. Close the **Edit Axis** dialog.

For a more complex use case, first follow the steps in [Example: Swap Measures Using Parameters](#). Then, follow these steps:

1. Double-click on the X axis to open the **Edit Axis** dialog.
2. Under the **Axis Titles** section, select **Parameter**, and then choose Placeholder 2 selector.
3. Close the **Edit Axis** dialog.
4. Repeat these steps for the Y axis using Placeholder 1.

Now, when the parameters are changed, the axes titles update to reflect the data being displayed.

Understand limitations and edge cases

Dynamic axis titles are cleared when the viz type is changed using Show Me. Also if you use subtitles, then the subtitle appears after the Dynamic Axis Title, just as it does for custom titles. Automatic subtitles are populated only when you have a continuous date value axis that is filtered to a single year with at least two time periods.

Use Dynamic Zone Visibility

Dashboard space is valuable, especially when you want to progressively reveal insights about data. With Dynamic Zone Visibility, you can hide or reveal zones (tiled or floating dashboard elements) based on the value of a field or parameter. As you interact, zones on your dashboard appear or disappear. The result is a dynamic dashboard that doesn't compromise your desired layout.

While you can [show or hide objects by clicking a button on a dashboard](#), Dynamic Zone Visibility allows you to show and hide objects automatically. This is ideal for dashboards that are used by different user groups. For example, you might want to show different user groups different zones when they visit your dashboard.

And you can use Dynamic Zone Visibility with [Parameter Actions](#). For example, when a user clicks a mark on a viz, a previously hidden zone appears. This is ideal for complex dashboards because it allows you to choose when deeper levels of data are revealed.

Supported field types

To be used for Dynamic Zone Visibility, a field or parameter must be:

- Boolean.
- Single value.
- Independent of the viz, meaning the field returns a constant value independent of the structure of the viz, such as a fixed level of detail (LOD) calculation.

Configure a dynamic dashboard zone

The following example has two sheets that use [Superstore data](#): the first sheet has a bar chart with Sales by Category, and the second sheet has a bar chart with Sales by Sub-Category. By using Dynamic Zone Visibility, the second sheet is visible only after a mark is clicked in the Sales by Category zone. This example relies on a boolean calculated field, which is used as the source field for a parameter action. For the calculation to be used as the source field for the parameter action, the calculation must be added to the marks card.

1. From the Sales by Category sheet, [create a parameter](#). In this example, the parameter **Data type** must be set to **Boolean**.
2. From the Sales by Category sheet, [create a calculated field](#). This example uses the following calculation: `True`
3. On the Sales by Category sheet, drag the calculation that you created to **Details** on the marks card.
4. Create a dashboard.
5. Drag the sheet that you always want to be visible onto your dashboard. In our example, we want Sales by Category to be visible.
6. From your dashboard, click the Sales by Category zone (dashboard object). Then, from the Worksheet menu on your dashboard, [create a parameter action](#). This example uses the following **Change Parameter** action:
The source sheet is set to use the dashboard you created and the Category Sales sheet.
The **Target Parameter** is the parameter you created.

The **Source Field** is the calculation you created.

Add Parameter Action

Name

Dynamic zone action Insert ▼

☒ Select

☐ Menu

Target Parameter

T/F Hide zone with parameter ▼

Clearing the selection will

☐ Keep current value

☒ Set value to

Source Field **Aggregation**

T/F Calc for dy... ▼ None ▼

False ▼

Cancel OK

7. Drag the Sales by Sub-Category worksheet onto your dashboard.
8. Click the Sales by Category zone. From the upper right corner, click the dropdown arrow and select **Use as Filter**.
9. Click the Sales by Sub-Category zone, and then click the **Layout** tab.
10. Check the box for **Control visibility using value**.
11. From the dropdown, choose the parameter you created to control zone visibility.

Note: If the option to Control visibility using value doesn't contain the field you want to use, be sure that the field is a supported field type.

Now, when you click a category mark in the Sales by Category zone, the Sales by Sub-Category zone appears in your dashboard.

Workbook Optimizer

The Workbook Optimizer is a tool that identifies if a workbook follows certain performance best practices. These guidelines are limited to what can be parsed from the workbook's

metadata and evaluated by a rules engine algorithm. Not all of its recommendations are applicable to or appropriate for every workbook. There are many aspects of performance that aren't captured by the Optimizer, some of which can offer easy wins. For more information, refer to [Streamline your workbook](#) and the whitepaper [Designing Efficient Production Workbooks](#).

Run the Workbook Optimizer

The Workbook Optimizer is available from the publishing menu and publishing dialog in web authoring.

1. From the **File** menu, select **Publish** or **Publish As**. Alternatively, click the drop down next to Publish.
2. Click **Run Optimizer**. This opens a new dialog for the Workbook Optimizer.
3. The workbook is automatically evaluated against the guidelines and results display in one of three categories: Take action, Needs review, or Passed (or Passed and ignored).
 - You may see fewer than three categories. If no guidelines fall into a category, it doesn't display.
 - Expand each category to see the guidelines. You can also expand each guideline for more information about why it's a recommendation. Some have additional information specific to your workbook:
 - You can choose to address any or none of the guidelines. As running the Optimizer is a voluntary step in the publishing process, it doesn't prevent you from being able to publish.
4. To close the dialog and go back to the workbook, click Close.
5. To close the dialog and go back to (or open) the publishing dialog, click Publish.

The Workbook Optimizer is available from the publishing menu and publishing dialog in web authoring.

Optimizer categories

The Optimizer breaks down its guidelines into three categories: take action, needs review, and passed.

Take action indicates that updating the workbook to follow these best practices have minimal to no impact on the functionality of the workbook. There's probably no reason to avoid making these changes.

Needs review indicates that following these best practices may involve modifying the workbook in more involved ways, such as restructuring a data source or simplifying a dashboard.

- For these guidelines, use your best judgment to determine what is possible or practical to address.
- Some recommendations may involve a lot of effort for minimal performance gain and aren't worth it.
- It may be useful to use the Performance Recorder to get a performance benchmark.
- Some may be deliberate choices you've made.

As the author, you're the final authority on what makes a workbook as efficient as possible. *Remember that some best practices should be broken to effectively deliver content.* Always weigh the goal of the workbook against changes to improve performance.

Passed indicates the guidelines are met and the workbook is already following best practices in that area. But remember, there are many aspects of performance that aren't captured by the Optimizer. This category is renamed **Passed and ignored** if any guidelines are ignored for the workbook.

Ignore a guideline

Guidelines aren't always applicable to your situation. Perhaps you're publishing a template workbook for others to use and need to preserve unused fields and data sources. You don't want the optimizer to continue to notify you about those guidelines.

It's possible to ignore a guideline for a workbook.

1. From a specific guideline, click the **Ignore** button.
 - The guideline is muted and moves to the **Passed and ignored** section. Even if you run the optimizer again, that guideline won't appear in the Take action or Needs review section.
2. To resume evaluating the guideline, find its row in the **Passed and ignored** section and click the **Ignore** button again.
 - The optimizer runs again and the guideline is evaluated. It continues to be checked each time the optimizer runs.

Autofix a guideline

Some suggestions from the workbook optimizer can be implemented without user input. For these guidelines, there's a button to autofix the rule. If the button doesn't appear you must manually address the issue.

From a specific guideline, click the Autofix button.

- The recommended action (such as closing an unused data source) is taken behind the scenes and the guideline moves to the Passed section.
- If the autofix fails for any reason, you'll be notified and prompted to resolve the issue manually.
- If the button isn't available, that guideline cannot be autofixed and must be addressed manually.

The guidelines

Every guideline contains a “consider” statement that suggests a potential way to address the performance impact. These are necessarily general and may not apply in every situation. These suggestions are a starting point only; always frame your decisions in the context of your environment and the goals of your workbook.

Note: Not all suggestions are possible to perform in the browser and may require **editing in Tableau Desktop** instead.

Navigate to a guideline by letter: **A . B . C . D . E . F . G . H . I . J . K . L . M . N . O . P . Q . R . S . T . U . V . W . X . Y . Z**

Calculation length

From the Workbook Optimizer

Sample output message: The calculation **My calculation** is 600 characters long

Computing the results of complex calculations can impact performance.

Consider breaking the calculation apart and moving whatever is possible to the database, or using Tableau Prep to create the calculations prior to analysis.

Additional information

Complex and long calculations can either be written in a single calculation or nested (with some components written as standalone calculations that are used in the larger calculation). Building a calculation with nested components may make it easier to troubleshoot and maintain, but it can add complications and additional processing. If possible, pushing these components back to the data source may aid performance.

Comments in calculations count against the length, so this guideline may be triggered by a long comment rather than a long and complex calculation.

Calculation uses multiple data sources

From the Workbook Optimizer

Sample output message: The data source **Supply Chain** includes 17 calculations using fields from another data source.

When calculations use fields from multiple data sources, Tableau can't use any optimizations and must compute the calculation locally.

Consider using Tableau Prep to create the calculation and using an extract.

Additional information

By moving the cross-database calculation to the data layer, the processing can be performed before the user even requests the dashboard. See [Join your data \(Prep\)](#) and [Create level of detail and rank calculations](#) for more information.

Under some conditions a parameter may trigger this guideline. If a calculation is indicated that doesn't use multiple data sources, check to see if it has a parameter and if that parameter can be simplified.

Dashboard size not fixed

From the Workbook Optimizer

Sample output message: The dashboard **Q3 analytics** isn't fixed size.

Fixed sized dashboards can be cached because they're a predictable size. Using automatic dashboard sizing means the results depend on the user's screen, and therefore the dashboard must be rendered every time. Rendering dashboards more often comes with a performance hit.

Consider using fixed dashboard sizing.

Additional information

Although responsive elements are a best practice in web design, letting your dashboard resize can distort the layout of the content in addition to the performance impact of re-rendering. For Tableau visualizations, it's best to use a **fixed dashboard size** and use **device-specific dashboards** to support different devices and screen sizes.

Filter uses conditional logic

From the Workbook Optimizer

Sample output message: The filter **Sample Type** uses conditional logic.

Dimension filtering can be done in various ways, such as on a list of values, by wildcard matching, or using conditional logic. Conditional logic can be slow.

Consider changing the filter to not use conditional logic. If necessary, make sure your logic tests for the most frequent outcome first and use ELSEIF or CASE when possible.

Additional information

For more information on filtering, see **Filter Your Data**.

Filter uses "Only Relevant Values"

From the Workbook Optimizer

Sample output message: The filter **Sample Type** uses "Only Relevant Values".

When a filter uses "Only Relevant Values", the interactive filter control only shows options that are applicable given the current state of the view. Every time a change is made to other filters, the list of values to be displayed must be requeried, which has a performance impact.

Consider using dashboard filter actions instead. If the end-user benefit is valuable enough that this feature should be used, consider extracting the data and optimizing the extract.

Additional information

There are situations where using "Only Relevant Values" is necessary to avoid an unwieldy filter list. Instead of using interactive filters in that situation, try using [action filters](#). For example, consider a dashboard that has cascading filters for Category, Sub-Category, and Product ID, where Product ID is set to show "Only Relevant Values". Removing that restriction would expand the list of products significantly. Rather than using filters, you can build simple visualizations (such as a bar chart of Category and Sub-Category) and use it as a filter. The user clicks on a bar and the action filter is applied to the rest of the visualizations on the dashboard. For more information, see [Dashboard Actions](#).

Live data connections

From the Workbook Optimizer

Sample output message: The data source **Supply Chain** isn't an extract.

Tableau extracts are designed to be as efficient as possible for use with analytics. Using extracts is one of the easiest ways to improve performance due to the data source. Extracts also have many native features for optimization.

Consider extracting the data source.

Additional information

In some instances, taking an extract may put undesirable strain on the Tableau Server or Tableau Site's resources. Work with your Tableau administrator to determine the best course of action.

The whitepaper [Designing Efficient Workbooks](#) has extensive information about extracts and how to use them for performance. (You may need to sign in to access the whitepaper.)

Multiple connections in a data source

From the Workbook Optimizer

Sample output message: The data source **Supply chain** uses multiple data connections.

Data sources that include multiple connections can't be computed locally.

Consider combining the data sources in Tableau Prep and using an extract for analysis.

Additional information

See [Join your data \(Prep\)](#) for more information.

Nested calculations

From the Workbook Optimizer

Sample output message: The calculation **My Calculation** references another calculation.

Nesting calculations can add complications and additional processing, especially with IF statements and other performance intensive functions.

Consider pushing the calculations to the data source or materialize them in an extract.

Additional information

This rule may be triggered for a calculation that isn't in the viz itself but is referenced by a calculation in the viz. For example, imagine four fields:

1. **Points earned** (a field in the data source)
2. **Quiz score** = [Points earned]*10
3. **Curved grade** = [Quiz score]*1.05
4. **Letter grade** = IF [Curved grade] >= 90 THEN "A" ELSEIF [Curved grade] >= 80 THEN "B" ELSEIF [Curved grade] >=70 THEN "C" ELSEIF [Curved grade] >=60 THEN "D" ELSE "F" END

Quiz score is a non-nested calculation that only references a field. Both **Curved grade** and **Letter grade** are nested calculations because they contain references to other calculations. Even if only **Letter grade** is used in the viz, **Curved grade** also triggers the nested calculation rule because it's in use inside **Letter grade**.

For more information on materializing calculations in an extract (Compute Calculations Now), see [Materialize Calculations in Your Extracts](#).

For more information about building calculations in Tableau Prep, see [Calculations in Tableau Prep](#).

Non-materialized calculations

From the Workbook Optimizer

Sample output message: The data source **Supply Chain** hasn't been pre-computed.

Computing the results of a calculation can impact performance.

Consider pushing calculations to the data source when possible. If using an extract, materialize calculations to pre-compute their results.

Additional information

Pre-compute the data and calculations either in an extract or your back-end data source. By moving this additional processing to the data layer, the processing is completed before the user even requests the dashboard.

Taking an extract of your data often boosts performance, though there are tradeoffs in data freshness and some functionality. See [Extract Your Data](#) for more information about options

for extracts and [Materialize Calculations in Your Extracts](#) for more information on materializing calculations.

Extract your data: right click on the data source's name at the top of the Data pane and select **Extract Data**. In the configuration dialog, choose **Compute Calculations Now**.

Number of data sources

From the Workbook Optimizer

Sample output message: The workbook contains 17 data sources.

Each data source contributes to the amount of time Tableau spends loading and rendering a workbook.

Consider combining data sources if possible, especially when the level of granularity is the same or they support the same analysis.

Additional information

See [Relate Your Data](#) for more information on combining data sources, or consider using Tableau Prep.

However, be wary of over-combining data sources. Workbooks perform best when each type of analysis is built off a well-designed data source. If it's hard to combine your data sources, this could be a sign that the analysis should be split into multiple workbooks, each with a more targeted purpose.

To split your analysis across multiple workbooks, try one of these methods:

- Save a copy of the workbook and delete unnecessary sheets, dashboards, and data sources from each one. See [Streamline your workbook](#) for more information.
 - Copy specific sheets into a new workbook. This may be more efficient because copying a dashboard into a new workbook carries over only what is needed for that dashboard. However, not all formatting options are transferred. See [Copying Information Between Workbooks](#) for more information.
-

Number of filters

From the Workbook Optimizer

Sample output message: The sheet **Classroom Distribution** contains 17 filters.

Excessive filters on a view create a more complex query.

Consider reducing the number of filters and using filter actions wherever possible. Not all types and formats of filters are created equal in terms of performance, so consider optimizing necessary filters.

Additional information

The whitepaper [Designing Efficient Production Workbooks](#) has an entire section on filters that goes into much more detail. In brief:

- Reduce the overall number of filters
- Filters applied to multiple worksheets trigger multiple queries with every change
- Limit use of **Show only relevant values**. Using an extract helps optimize this feature if it's needed.
- Avoid high cardinality include/exclude filters
- Use the **Apply** button to prevent multiple refreshes as the user interacts with the filter
- Filter on fields that are present in the view
- Use continuous date filters rather than discrete date filters
- Context filters shouldn't be used purely to boost performance

Filter actions are an efficient way to guide the user through a dashboard. See [Filter Actions](#) for more information.

Number of layout containers

From the Workbook Optimizer

Sample output message: The dashboard **Q3 analytics** contains 42 layout containers.

Layout containers can complicate dashboard rendering.

Consider removing unnecessary layout containers and simplifying the dashboard design.

Additional information

For more information about layout containers and the Layout pane, see [Group items using layout containers](#).

Number of LOD calculations

From the Workbook Optimizer

Sample output message: The workbook contains 42 LOD calculations.

Computing the results of complex calculations can impact performance. Often, LODs are used on the fly to address issues of granularity in the data source that could be handled prior to analysis.

Consider tailoring the data source to the analysis to avoid the need for as many LODs.

Additional information

Level of Detail calculations are powerful tools, but they're expensive. Make sure you're only using them when necessary.

Production databases are designed to handle significant query loads and are a great option for moving processing out of Tableau. FIXED LOD calculations can sometimes be performed by the database. Tableau Prep also supports FIXED LOD calculations. See [Create level of detail and rank calculations](#) for more information.

Number of views in a dashboard

From the Workbook Optimizer

Sample output message: Dashboard **Q3 analytics** contains 17 views

A dashboard must load all elements before it can be displayed. The more views a dashboard contains, the longer it takes to load. Although it often involves a redesign, reducing the number of views in a dashboard is often the best way to boost its efficiency.

Consider streamlining the dashboard to be as effective and simple as possible by reducing the number of views, filters, and other elements. Start with anything that can be removed immediately. See [Streamline your workbook](#) for other ways to reduce clutter in your dashboard.

Additional information

If a more substantial redesign is needed, remember that not all views have an equal impact on performance. Focus on sheets with the most marks, filters, or other complexity. A good strategy can be to limit the initial dashboard to summary information and only provide more details when the user requests them. There are many strategies for this sort of guided drill-down, including:

- Use action filters. See [Filter Actions](#) for more information.
- Hide detailed views in a container using a layout container with a show/hide button. See [Show and hide objects by clicking a button](#) for more information.
- Break the dashboard into multiple dashboards and use navigation buttons. See [Detailed options for Navigation and Download objects](#) for more information.

Number of workbook sheets

From the Workbook Optimizer

Sample output message: The workbook contains 42 visible sheets

The overall size of a workbook impacts how long it takes to be processed and displayed. All visible sheets must be loaded before Tableau can display a workbook or view. Reducing the number of sheets can help speed up load time.

Consider reducing the number of sheets in the workbook by closing unneeded sheets, hiding sheets that are used in a dashboard, or splitting the analysis into multiple workbooks.

Additional information

Delete sheets that aren't necessary for the analysis: right click on the sheet tab along the bottom of the workbook and select Delete.

Hide sheets in use: Worksheets used in a dashboard or story can't be deleted, but they can be hidden. See [Manage Sheets in Dashboards and Stories](#) for more information.

- Hide all of a dashboard's sheets: right-click the dashboard tab at the bottom of the workbook and select Hide All Sheets.
- Hide a specific sheet: right click the sheet tab at the bottom of the workbook and select Hide.

If all sheets are needed, decide if the analysis can be split into multiple workbooks, each with a more targeted purpose.

- Save a copy of the workbook and delete unnecessary sheets, dashboards, and data sources from each one. See [Streamline your workbook](#) for more information.
- Copy specific sheets into a new workbook. This may be more efficient because copying a dashboard into a new workbook carries over only what is needed for that dashboard. However, not all formatting options are transferred. See [Copying Information Between Workbooks](#) for more information.

Unused data sources

From the Workbook Optimizer

Sample output message: The data source **Supply Chain** isn't used in the workbook.

Each data source contributes to the amount of time Tableau spends loading and rendering a workbook.

Consider closing data sources that aren't in use.

Additional information

If any data sources aren't being used, close them: right click on the data source's name at the top of the Data pane and select **Close**.

Unused fields

From the Workbook Optimizer

Sample output message: The data source **Supply Chain** contains 42 fields that aren't being used.

Hiding unused fields prevents them from being unnecessarily queried and reduce the size of extracts.

Consider hiding any fields that aren't being used, regardless of whether the data source is an extract.

Additional information

Hide unused fields

- In Tableau Desktop: open the dropdown menu at the top of the Data pane and select **Hide All Unused Fields**.
 - In web authoring: right click on an unused field and select **Hide**. There's no way to bulk hide unused fields in web authoring. If hiding fields individually is prohibitive, consider [editing in Tableau Desktop](#) instead of working in the browser.
-

Uses data blending

From the Workbook Optimizer

Sample output message: The sheet **Classroom Distribution** uses data blending.

Data blending performance is driven by the number of unique members in the linking fields.

Consider using relationships when possible. If a blend is required, try to use low cardinality linking fields.

Additional information

There are [several ways to combine data](#) from multiple sources. [Data blending](#) sends two separate queries to two separate data sources and displays the results together in the viz. These

queries are at the level of the [linking fields](#) and the results are merged in memory in Tableau. Large query results require more processing to generate the final viz.

Tip: If you aren't using data blending but the Workbook Optimizer failed this rule, check if the workbook is using [cross data source filtering](#). Filtering across data sources suffers from similar performance issues around field cardinality.

Uses date calculations

From the Workbook Optimizer

Sample output message: The data source **Supply Chain** contains 17 date calculations.

Date logic can be complicated. Minimize the number of date calculations and conversion you have to do in Tableau.

Consider using DATEPARSE and MAKEDATE before other methods, and try to use built-in functions like DATEDIFF() when possible. If filtering on a date, use relative date filters or a continuous date filter instead of a discrete filter.

Additional information

Computing calculations in Tableau can have a significant performance impact, especially [date functions](#). Consider taking an extract and [materializing calculations](#), or pushing calculations to your data source. For more information about building calculations in Tableau Prep, see [Create Calculations in Tableau Prep](#).

Note: If a date calculation is nested in another calculation, the optimizer flags the nested date calculation, even if the parent calculation is the field used in the viz.

Uses grouping

From the Workbook Optimizer

Sample output message: The data source **Supply Chain** uses 17 grouped fields

Tableau's native grouping functionality loads the entire domain of the field, which can have a performance impact.

Consider using a calculated field with a CASE statement or sets instead of groups.

Additional information

In the testing performed for the [Designing Efficient Workbooks](#) whitepaper, grouping with CASE and sets performed better than the native group functionality.

The **CASE** function can be used to create groups. Imagine a scenario where the data involved a deck of cards. There's a field for the card value (2–10, J, Q, K, A) but the analysis should compare face cards to number cards. The case statement to make that grouping could be

```
CASE [Value]
  WHEN "J" THEN "Face card"
  WHEN "Q" THEN "Face card"
  WHEN "K" THEN "Face card"
  ELSE "Number card"
END
```

Sets have the added benefit of set actions, which make sets more powerful and flexible than traditional grouping. For more information, see [Create Sets](#) and [Set Actions](#).

Manage Server

After installing Tableau Server, you can customize and manage your server. For example, you can manage security, licenses, sites, subscriptions and data-driven alerts, and more.

Security	1126

Quick Help Overview	3269

Security

As a part of managing Tableau Server, you can configure authentication, data security, and network security.

Authentication

Authentication verifies a user's identity. Everyone who needs to access Tableau Server—whether to manage the server, or to publish, browse, or administer content—must be represented as a user in the Tableau Server repository. The method of authentication may be performed by Tableau Server (“local authentication”), or authentication may be performed by an external process. In the latter case, you must configure Tableau Server for external authentication technologies such as Kerberos, SSPI, SAML, or OpenID. In all cases, whether authentication takes place locally or is external, each user identity must be represented in the Tableau Server repository. The repository manages authorization meta data for user identities.

Looking for Tableau Server on Linux? See [Authentication](#).

Although all user identities are ultimately represented and stored in the Tableau Server repository, you must manage user accounts for Tableau Server in an identity store. There are two, mutually exclusive, identity store options: LDAP and local. Tableau Server supports arbitrary LDAP directories, but it's been optimized for Active Directory LDAP implementation. Altern-

actively, if you are not running an LDAP directory, you can use the Tableau Server local identity store. For more information see Identity Store.

As shown in the following table, the type of identity store you implement, in part, will determine your authentication options.

Identity Store	Authentication Mechanism								
	Basic	SAML	Site SAML	Kerberos	(Windows only) Automatic Logon (Microsoft SSPI)	OpenID Connect	Connected Apps	Trusted Auth	Mutual SSL
Local	X	X	X			X	X	X	X
Active Directory	X	X		X	X		X	X	X
LDAP	X	X					X	X	X

Access and management permissions are implemented through site roles. Site roles define which users are administrators, and which users are content consumers and publishers on the server. For more information about administrators, site roles, groups, Guest User, and user-related administrative tasks, see [Users](#) and [Site Roles for Users](#).

Note: In the context of authentication, it's important to understand that users are not authorized to access external data sources through Tableau Server by virtue of having an account on the server. In other words, in the default configuration, Tableau Server does not act as a proxy to external data sources. Such access requires additional configuration of the data source on Tableau Server or authentication at the data source when the user connects from Tableau Desktop.

Add-on authentication compatibility

Some authentication methods can be used together. The following table shows authentication methods that can be combined. Cells marked with an "X" indicate a compatible authentication set. Blank cells indicate incompatible authentication sets.

	Con- nected Apps	Trusted Authentic- ation	Serve- r-wide SAML	Site SAM- L	Ker- beros	(Win- dows only) Auto- matic Logon (Micros- oft SSPI)	Mutu- al SSL	OpenI- D Con- nect
Tableau Connected Apps	N/A		X	X	X			
Trusted Authentic- ation		N/A	X	X	X		X	X
Server-	X	X	N/A	X				

Tableau Server on Windows Help

wide SAML								
Site SAML	X	X	X	N/A				
Kerberos	X	X			N/A			
Automatic Logon (Microsoft SSPI)						N/A		
Mutual SSL	X	X					N/A	
OpenID Connect	X	X						N/A
Personal Access Token (PAT)	*	*	*	*	*	*	*	*

* PATs, by design, do not work directly with the authentication mechanism listed in these columns to authenticate to the REST API. Instead, PATs use Tableau Server user account credentials to authenticate to the REST API.

Client authentication compatibility

Authentication handled through a user interface (UI)

Clients	Authentication Mechanism									
	Basic	SA-ML	Site SA-ML	Kerberos	(Windows only) Automatic Logon (Microsoft SSPI)	Open-ID Connect	Connected Apps	Trusted Auth	Mutual SSL	Personal Access Token (PAT)
Tableau Desktop	X	X	X	X	X	X			X	
Tableau Prep Builder	X	X	X	X	X	X			X	
Tableau Mobile	X	X	X	X (iOS only)	X *	X			X	
Web	X	X	X	X	X	X	X	X	X	

Tableau Server on Windows Help

Browsers							**			
----------	--	--	--	--	--	--	----	--	--	--

* SSPI is not compatible with the Workspace ONE version of the Tableau Mobile app.

** In embedding workflows only.

Authentication handled programmatically

Clients	Authentication Mechanism									
	Basic	SA-ML	Site SA-ML	Kerberos	(Windows only) Automatic Logon (Microsoft SSPI)	Open-ID Connect	Connected Apps	Trusted Auth	Mutual SSL	Personal Access Token (PAT)
REST API	X						X			X
tabcmd 2.0	X									X
tabcmd	X									

Local authentication

If the server is configured to use local authentication, then Tableau Server authenticates users. When users sign-in and enter their credentials, either through Tableau Desktop, `tabcmd`, API, or web client, Tableau Server verifies the credentials.

To enable this scenario, you must first create an identity for each user. To create an identity, you specify a username and a password. To access or interact with content on the server, users must also be assigned a site role. User identities can be added to Tableau Server in the server UI, using [tabcmd Commands](#), or using the [REST API](#).

You can also create groups in Tableau Server to help manage and assign roles to large sets of related user groups (e.g., “Marketing”).

When you configure Tableau Server for local authentication, you can set password policies and account lockout on failed password attempts. See [Local Authentication](#).

Note: Tableau with multi-factor (MFA) authentication is available for Tableau Cloud only.

External authentication solutions

Tableau Server can be configured to work with a number of external authentication solutions.

NTLM and SSPI

If you configure Tableau Server to use Active Directory during installation, then NTLM will be the default user authentication method.

When a user logs onto Tableau Server from Tableau Desktop or a web client, the credentials are passed through to Active Directory, which then verifies them and sends an access token to Tableau Server. Tableau Server will then manage user access to Tableau resources based on the site roles stored in the repository.

If Tableau Server is installed on a Windows computer in Active Directory, then you may optionally enable automatic logon. In this scenario, Tableau Server will use Microsoft SSPI to auto-

matically sign in your users based on their Windows username and password. This creates an experience similar to single sign-on (SSO).

Do not enable SSPI if you plan to configure Tableau Server for SAML, trusted authentication, a load balancer, or for a proxy server. SSPI is not supported in these scenarios. See `tsm authentication sspi <commands>`.

Kerberos

You can configure Tableau Server to use Kerberos for Active Directory. See [Kerberos](#).

SAML

You can configure Tableau Server to use SAML (security assertion markup language) authentication. With SAML, an external identity provider (IdP) authenticates the user's credentials, and then sends a security assertion to Tableau Server that provides information about the user's identity.

For more information, see [SAML](#).

OpenID Connect

OpenID Connect (OIDC) is a standard authentication protocol that lets users sign in to an identity provider (IdP) such as Google. After they've successfully signed in to their IdP, they are automatically signed in to Tableau Server. To use OIDC on Tableau Server, the server must be configured to use the local identity store. Active Directory or LDAP identity stores are not supported with OIDC. For more information, see [OpenID Connect](#).

Mutual SSL

Using mutual SSL, you can provide users of Tableau Desktop, Tableau Mobile, and other approved Tableau clients a secure, direct-access experience to Tableau Server. With mutual SSL, when a client with a valid SSL certificate connects to Tableau Server, Tableau Server confirms the existence of the client certificate and authenticates the user, based on the username in the client certificate. If the client does not have a valid SSL certificate, Tableau Server can refuse the connection. For more information, see [Configure Mutual SSL Authentication](#).

Connected apps

Direct trust

Tableau connected apps enable a seamless and secure authentication experience by facilitating an explicit trust relationship between your Tableau Server site and external applications where Tableau content is embedded. Using connected apps also enables a programmatic way to authorize access to the Tableau REST API using JSON Web Tokens (JWTs). For more information, see [Configure Tableau Connected Apps to Enable SSO for Embedded Content](#).

EAS or OAuth 2.0 trust

You can register an external authorization server (EAS) with Tableau Server to establish a trust relationship between your Tableau Server and an EAS using the OAuth 2.0 standard protocol. The trust relationship provides your users with single sign-on experience, through your IdP, to embedded Tableau content. In addition, registering an EAS enables a programmatic way to authorize access to the Tableau REST API using JSON Web Tokens (JWTs). For more information, see [Register EAS to Enable SSO for Embedded Content](#).

Trusted authentication

Trusted authentication (also referred to as "Trusted tickets") lets you set up a trusted relationship between Tableau Server and one or more web servers. When Tableau Server receives requests from a trusted web server, it assumes that the web server has already handled whatever authentication is necessary. Tableau Server receives the request with a redeemable token or ticket and presents the user with a personalized view which takes into consideration the user's role and permissions. For more information, see [Trusted Authentication](#).

LDAP

You can also configure Tableau Server to use LDAP for user authentication. Users are authenticated by submitting their credentials to Tableau Server, which will then attempt to

bind to the LDAP instance using the user credentials. If the bind works then the credentials are valid and Tableau Server grants the user a session.

“Binding” is the handshake/authentication step that happens when a client tries to access an LDAP server. Tableau Server does this for itself when it makes various non-authentication related queries (such as importing users and groups).

You can configure the type of bind you want Tableau Server to use when verifying user credentials. Tableau Server supports GSSAPI and simple bind. Simple bind passes credentials directly to the LDAP instance. We recommend that you configure SSL to encrypt the bind communication. Authentication in this scenario may be provided by the native LDAP solution, or with an external process, like SAML.

For more information about planning for and configuring LDAP, see [Identity Store and External Identity Store Configuration Reference](#).

Other authentication scenarios

- REST API: [Signing In and Out \(Authentication\)](#)

Note: REST API does not support SAML single-sign (SSO).

- Mobile device authentication: [Single sign-on for Tableau Mobile](#)
- Certificate trust for TSM clients: [Connecting TSM clients](#)

Data access and source authentication

You can configure Tableau Server to support a number of different authentication protocols to various different data sources. Data connection authentication may be independent of Tableau Server authentication.

For example, you may configure user authentication to Tableau Server with local authentication, while configuring OAuth or SAML authentication to specific data sources. See [Data Connection Authentication](#).

Local Authentication

If the server is configured to use local identity store, then Tableau Server authenticates users. When users sign-in and enter their credentials, either through Tableau Desktop, tabcmd, API, or web client, Tableau Server verifies the credentials. Tableau user names stored in the identity store are associated with rights and permissions for Tableau Server. After authentication is verified, Tableau Server manages user access (authorization) for Tableau resources.

To use local authentication, you must configure Tableau Server with a local identity store during Setup. You cannot use local authentication if your Tableau Server has been configured with an external identity store (LDAP, Active Directory, etc).

Note: Identity pools, which is a tool designed to complement and support additional user provisioning and authentication options you might need in your organization, supports OpenID Connect (OIDC) authentication only. For more information, see [Provision and Authenticate Users Using Identity Pools](#).

Password storage

When local authentication is used, the user's salted and hashed password is stored in the repository. Passwords are never stored directly, rather, the result of salting and hashing the password is stored. Server uses the PBKDF2 derivation function with the HMAC SHA512 hashing function.

Configure password settings

After you install Tableau Server with local authentication, you can use Tableau Server Manager (TSM) to configure a number of password-related settings:

- Password policies: these policies define the requirement for password structure, such as length, character types, and other requirements.
- Password expiration: enable and specify password expiry.

- **Login rate limit:** Tableau Server throttles the time between sign-in attempts after users enter 5 incorrect passwords. Users will need to wait a few seconds before attempting another sign-in. If users continue to enter incorrect passwords, then they must wait for exponentially longer periods of time in between sign-in attempts. By default, the maximum time between sign-in attempts is 60 minutes.

Lock out account access after too many failed attempts. You can specify how many failed attempts users are allowed to enter before they are locked out. For information on how to unlock access to a locked account, see [View and manage users on a site](#).

- **User password reset:** Enable users to reset passwords. Enabling password reset will configure Tableau Server to display a link on the sign-in page. Users who forget passwords or want to reset a password can click the link to initiate a reset-password workflow. Password reset must be configured using TSM CLI, as described below.

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click on **User Identity & Access** on the **Configuration** tab and then click **Authentication Method**.
3. Select Local authentication from the drop-down menu to display the password settings.
4. Configure the password settings and then click **Save Pending Changes**.
5. Click **Pending Changes** at the top of the page:

6. Click **Apply Changes and Restart**.

Use the TSM CLI

For the initial configuration of password policies, we recommend that you use the configuration file template below to create a json file. You can also set any single configuration key listed below with the syntax described in tsm configuration set.

1. Copy the following json template to a file. Fill in the key values with your password policy configuration. See the reference section that follows for more information about key options.

```
{
  "configKeys": {
    "wgserver.localauth.policies.mustcontainletters.enabled":
    false,
    "wgserver.localauth.policies.mustcontainuppercase.enabled":
    false,
    "wgserver.localauth.policies.mustcontainnumbers.enabled":
    false,
    "wgserver.localauth.policies.mustcontainsymbols.enabled":
    false,
    "wgserver.localauth.policies.minimumpasswordlength.enabled":
    false,
    "wgserver.localauth.policies.minimumpasswordlength.value": 8,
    "wgserver.localauth.policies.maximumpasswordlength.enabled":
    false,
    "wgserver.localauth.policies.maximumpasswordlength.value":
    255,
    "wgserver.localauth.passwordexpiration.enabled": false,
    "wgserver.localauth.passwordexpiration.days": 90,
    "wgserver.localauth.ratelimiting.maxbackoff.minutes": 60,
    "wgserver.localauth.ratelimiting.maxattempts.enabled": false,
```

Tableau Server on Windows Help

```
"wgserver.localauth.ratelimiting.maxattempts.value": 5,  
"features.PasswordReset": false  
}  
}
```

2. Run the `tsm settings import -f file.json` to pass the json file with the appropriate values to Tableau Services Manager to configure Tableau Server.
3. Run the `tsm pending-changes apply` command to apply the changes. See `tsm pending-changes apply`.

Configuration file reference

This section lists all of the options that can be used to configure password policies.

`wgserver.localauth.policies.mustcontainletters.enabled`

Default value: `false`

Require at least one letter in passwords.

`wgserver.localauth.policies.mustcontainuppercase.enabled`

Default value: `false`

Require at least one upper-case letter in passwords.

`wgserver.localauth.policies.mustcontainnumbers.enabled`

Default value: `false`

Require at least one number letter in passwords.

`wgserver.localauth.policies.mustcontainsymbols.enabled`

Default value: `false`

Require at least one special character in passwords.

```
wgserver.localauth.policies.minimumpasswordlength.enabled
```

Default value: `false`

Enforce minimum-length passwords.

```
wgserver.localauth.policies.minimumpasswordlength.value
```

Default value: 8

The minimum number of characters passwords must have. Enter a value between 4 and 255, inclusive. You must set `wgserver.localauth.policies.minimumpasswordlength.enabled` to `true` to enforce this value.

```
wgserver.localauth.policies.maximumpasswordlength.enabled
```

Default value: `false`

Enforce maximum-length passwords.

```
wgserver.localauth.policies.maximumpasswordlength.value
```

Default value: 255

The maximum number of characters passwords may have. Enter a value between 8 and 225, inclusive. You must set `wgserver.localauth.policies.maximumpasswordlength.enabled` to `true` to enforce this value.

```
wgserver.localauth.passwordexpiration.enabled
```

Default value: `false`

Enforce password expiry.

Tableau Server on Windows Help

`wgserver.localauth.passwordexpiration.days`

Default value: 90

The number of days before a password expires. Enter a value between 1 and 365, inclusive. You must set `wgserver.localauth.passwordexpiration.enabled` to `true` to enforce this value.

`wgserver.localauth.ratelimiting.maxbackoff.minutes`

Default value: 60

Maximum time between sign-in attempts after a user enters multiple incorrect passwords. Enter a value between 5 and 1440, inclusive.

`wgserver.localauth.ratelimiting.maxattempts.enabled`

Default value: `false`

Enforce account lock out after 5 incorrect passwords are entered. To change the number of incorrect passwords that will trigger account lock out, you set `wgserver.localauth.ratelimiting.maxattempts.value`.

`wgserver.localauth.ratelimiting.maxattempts.value`

Default value: 5

The number of incorrect passwords that a user may enter to trigger account lock out. Enter a value between 5 and 100, inclusive. You must set `wgserver.localauth.ratelimiting.maxattempts.enabled` to `true` to enforce this value.

`features.PasswordReset`

Default value: `false`

Enable users to reset passwords. Tableau Server must be configured to send email for this feature to operate. See [Configure SMTP Setup](#).

SAML

SAML (Security Assertion Markup Language) is an XML standard that allows secure web domains to exchange user authentication and authorization data. You can configure Tableau Server to use an external identity provider (IdP) to authenticate users over SAML 2.0. No user credentials are stored with Tableau Server, and using SAML enables you to add Tableau to your organization's single sign-on environment.

You can use SAML server wide, or you can configure sites individually. Here's an overview of those options:

- **Server-wide SAML authentication.** A single SAML IdP application handles authentication for all Tableau Server users. Use this option if your server has only the Default site, as it is unnecessary to configure site specific SAML in this case. You may also use Server-wide SAML in multisite environments, but users are limited to a single IdP to across all sites.
- **Server-wide local authentication and site-specific SAML authentication.** In a multi-site environment, users who are not enabled for SAML authentication at the site level can sign in using local authentication.
- **Server-wide SAML authentication and site-specific SAML authentication.** In a multi-site environment, all users authenticate through a SAML IdP configured at the site level, and you specify a server-wide default SAML IdP for users that belong to multiple sites.

If you want to use site-specific SAML, you must configure server-wide SAML before you configure individual sites. Server-side SAML does not need to be enabled for site-specific SAML to function, but it must be configured.

User authentication through SAML does not apply to permissions and authorization for Tableau Server content, such as data sources and workbooks. It also does not control access to underlying data that workbooks and data sources connect to.

Notes:

- Tableau Server supports both service provider initiated and IdP initiated SAML in browsers and in the Tableau Mobile app. SAML connections from Tableau Desktop must be service provider initiated.
- Identity pools, which is a tool designed to complement and support additional user provisioning and authentication options you might need in your organization, supports OpenID Connect (OIDC) authentication only. For more information, see Provision and Authenticate Users Using Identity Pools.

The following image shows the steps to authenticate a user with single sign-on in a typical service provider initiated flow:

1. User navigates to the Tableau Server sign-in page or clicks a published workbook URL.
2. Tableau Server starts the authentication process by redirecting the client to the configured IdP.
3. The IdP requests the user's username and password from the user. After the user submits valid credentials, the IdP authenticates the user.

4. The IdP returns the successful authentication in the form of a SAML Response to the client. The client passes the SAML Response to Tableau Server.
5. Tableau Server verifies that the username in the SAML Response matches a licensed user stored in the Tableau Server Repository. If a match is verified, then Tableau Server responds to the client with the requested content.

SAML Requirements

Before you configure SAML on Tableau Server, make sure your environment meets the requirements.

Important: SAML configurations, both with the IdP and on Tableau Server, are case sensitive. For example, URLs configured with the IdP and on Tableau Server must match exactly.

Certificate and identity provider (IdP) requirements

To configure Tableau Server for SAML, you need the following:

- **Certificate file.** A PEM-encoded x509 certificate file with a **.crt** extension. This file is used by Tableau Server, not the IdP. If you have an SSL certificate, it is possible in some circumstances to use the same certificate with SAML. For more information, see [Using SSL certificate and key files for SAML](#) later in this article.

Tableau Server requires a certificate-key pair to sign the request that is sent to the IdP. This reduces the threat of a man-in-the-middle attack given the difficulty of spoofing a signed request. Additionally, Tableau Server verifies that the AuthNResponse it receives from the trusted IdP. Tableau Server verifies the AuthNResponse by using the signature produced by the IdP. The IdP certificate metadata is provided to Tableau Server as part of the initial SAML configuration process.

Signed requests are not always necessary for all IdPs. By default, Tableau Server requires signed requests. We recommend this configuration to ensure a more secure communication transmission with the IdP. Work with your IdP team to understand if disabling signed requests is necessary. To disable signed requests see [samlSettings Entity](#).

- **Signature algorithm.** The certificate must use a secure signature algorithm, for example SHA-256. If you attempt to configure Tableau Server for SAML with a certificate that uses SHA-1 signature hash, Tableau Server will reject the certificate. You can configure Tableau Server to accept the less-secure SHA-1 hash by setting the `tsm wgserver.saml.blocklisted_digest_algorithms` configuration key.
- **RSA key and ECDSA curve sizes.** The Tableau Server certificate must have an RSA key strength of 2048, and the IdP certificate must have either an RSA key strength of 2048 or ECDSA curve size of 256.

You can configure Tableau Server to accept the less-secure sizes by setting the respective configuration keys, `wgserver.saml.min_allowed.rsa_key_size` and `wgserver.saml.min_allowed.elliptic_curve_size`.

- **Certificate key file.** An RSA or DSA private key file that has the **.key** extension. RSA keys must be in PKCS#1 or PKCS#8 format.

Password protection requirements are as follows:

- The PKCS#1 RSA key file cannot be password protected.
- To use a password-protected key file, you must configure SAML with a RSA PKCS#8 file. **Note:** A PKCS#8 file with a null password is not supported.
- Password-protected key files are not supported in site-specific SAML deployments.

Summary of support

Key file format	Server-Wide SAML Support	Site-Level SAML Support
PKCS#8 RSA	Yes	No
PKCS#8 (no/null password)	No	No

Key file format	Server-Wide SAML Support	Site-Level SAML Support
PKCS#1 RSA	Yes	Yes
PKCS#1 RSA (password)	No	No
PKCS#1 DSA (password)	No	No

- **IdP must sign SAML assertions with a secure signature algorithm.** By default, Tableau Server will reject SAML assertions signed with the SHA-1 algorithm. You can configure Tableau Server to accept assertions signed with the less-secure SHA-1 hash by setting the `tsm wgserver.saml.blocklisted_digest_algorithms` configuration key.
- **IdP account that supports SAML 2.0 or later.** You need an account with an external identity provider. Some examples are PingFederate, SiteMinder, and Open AM.
- **IdP provider that supports import and export of XML metadata.** Although a manually created metadata file might work, Tableau Technical Support cannot assist with generating the file or troubleshooting it.
- **Username:** Required. The IdP configuration must include the "username" attribute or claim and the corresponding SAML configuration attribute on Tableau Server must be set to "username" as well.

SSL off-loading

If your organization terminates SSL connections from the IdP at a proxy server before sending the authentication request to Tableau Server, then you may need to make a proxy configuration. In this scenario, SSL is "off-loaded" at the proxy server, which means the https request is terminated at the proxy server and then forwarded to Tableau Server over http.

Tableau Server validates the SAML response message returned from the IdP. Since SSL is off-loaded at the proxy, Tableau Server will validate with the protocol that it receives (http), but

the IdP response is formatted with `https`, so validation will fail unless your proxy server includes the `X-Forwarded-Proto` header set to `https`. See [Configure Tableau Server to work with a reverse proxy server and/or load balancer](#).

Using SSL certificate and key files for SAML

If you are using a PEM-encoded x509 certificate file for SSL, you can use the same file for SAML. For SSL, the certificate file is used to encrypt traffic. For SAML, the certificate is used for authentication.

In addition to the requirements listed in [Certificate and identity provider \(IdP\) requirements](#) above, to use the same certificate for both SSL and SAML, the certificate must also meet the following condition to work for SAML:

- Confirm that the certificate includes only the certificate that applies to Tableau Server and not any other certificates or keys.

To do this, you can create a backup copy of the certificate file, and then open the copy in a text editor to review its contents.

User management requirements

When you enable SAML, user authentication is performed outside of Tableau, by the IdP. However, user management is performed by an identity store: either an external identity store (Active Directory or LDAP) or by Tableau Server in a local identity store. For more information about planning for user management with Tableau Server, see [Identity Store](#).

When you configure the identity store during Setup, you must select the option that reflects how you want to use SAML. Note, if you want to use site-specific SAML, you must configure server-wide SAML before you configure individual sites.

- **For site-specific SAML:** If you have multiple sites on Tableau Server and want to set up each site for a particular IdP or IdP application (or configure some sites not to use SAML), configure Tableau Server to manage user with a local identity store. For site-specific SAML, Tableau Server relies on the IdP for authentication and does not use

passwords.

- **For server-wide SAML:** If you configure server-wide SAML with a single IdP, you can configure Tableau Server to use the local identity store or an external identity store. If you are using Active Directory (AD), you must disable the **Enable automatic logon** (Microsoft SSPI) option.
- **For both server-wide SAML authentication and site-specific SAML authentication:**
 - **When using a local identity store,** it is important that you use a username that has email address formatting. Using a complete email address helps to guarantee the uniqueness of the username in Tableau Server, even when two users have the same email prefix but have different email domains. To ensure uniqueness in identities, leverage full email address formatting across both systems or upgrade Tableau Server to version 2022.1.x or later and run the **identity migration** background job.
 - **In a multi-site environment,** all users authenticate through a SAML IdP configured at the site level. In this scenario, you specify a server-wide default SAML IdP for users who belong to multiple sites. To configure this scenario, Tableau Server must be configured with a local identity store.
 - **Ignore domain when matching SAML username attribute.** Beginning in Tableau Server versions 2021.4.21, 2022.1.17, 2022.3.9, and 2023.1.5, you can configure Tableau Server to ignore the domain portion of the username attribute when matching the identity provider (IdP) user name to a user account on Tableau Server. For example, the username attribute in the IdP might be `alice@example.com` to match a user named `alice` in Tableau Server. Ignoring the domain portion of the username attribute might be useful if you already have users defined in Tableau Server that match the prefix portion of the username attribute but not the domain portion of the username attribute.

Important: We do not recommend ignoring the domain name without taking precautions. Specifically, verify that user names are unique across the configured domains that you've created in your IdP. Configuring Tableau Server to ignore the domain name has the potential to result in unintended user sign-in. Consider the case where your IdP has been configured for multiple domains (e.g., `example.com` and `tableau.com`). If two users with the same first name, but different user accounts (e.g., `alice@tableau.com` and `alice@example.com`) are in your organization, then you could have a mapping mismatch.

To configure Tableau Server to ignore domain names in the username attribute from the IdP, set `wgserver.ignore_domain_in_username_for_matching` to `true`. For more information, see `wgserver.ignore_domain_in_username_for_matching`.

Notes:

- This command only works in Tableau Server deployments that are in `legacy-identity-mode` or deployments that have not been updated through the **identity migration** to use the Identity Service.
- When you change the tsm command to ignore the domain name in the username attribute, all user names in Tableau Server must have a domain name.

Note: The **REST API** and `tabcmd` do not support SAML single-sign (SSO). To sign in, you must specify the name and password of a user who has been created on the server. The user may be managed by the local identity store or an external identity store, depending on how you have configured Tableau Server. REST API or `tabcmd` calls will have the permissions of the user you sign in as.

SAML compatibility notes and requirements

- **Matching usernames:** The user name stored in Tableau Server must match the configured user name attribute sent by the IdP in the SAML assertion. By default, Tableau

Server expects the incoming assertion to contain an attribute called "username" with that user's information. For example, if the user name for Jane Smith is stored in PingFederate as **jsmith**, it must also be stored in Tableau Server as **jsmith**.

When configuring SAML during authentication

If you are configuring SAML as part of the initial Tableau Server setup, make sure the account you plan to use exists in your IdP before you run setup. During Tableau Server setup you create the server administrator account.

When running multiple domains

If you use an Active Directory or LDAP external identity store and you are running in multiple domains (that is, users belong to multiple domains, or your Tableau Server installation includes multiple domains), the IdP must send both the user name *and* domain attributes for a user in the SAML assertion. Both these user name and domain attributes must match exactly the user name and domain stored in Tableau Server. Do *one* of the following:

- Set `domain\username` in the username field
- Set domain in the domain field and set user name in the username field

When setting the domain attribute, you can use the fully qualified domain name (FQDN) or the shortname.

Where the domain isn't specified, it will be considered the default domain.

For more information, see Support for multiple domains and the "Match Assertions" section in the **Use TSM CLI** tab of Configure Server-Wide SAML.

- **Signature algorithm:** Tableau Server uses SHA256 signature algorithm.
- **Single Log Out (SLO):** Tableau Server supports both service provider (SP)-initiated SLO and identity provider (IdP)-initiated SLO for both server-wide SAML and site-specific SAML.

- **External authentication types:** Tableau Server supports using one external authentication type at a time.
- **Mutual SSL:** Tableau Server does not support mutual SSL (two-way SSL) and SAML together. If you want to use mutual SSL, you can configure it on the IdP.
- **Assertions encoding:** Assertions must be UTF-8 encoded.
- **Encryption and SAML assertions:**
 - **Server-wide SAML:** When Tableau Server is configured for server-wide SAML, Tableau Server supports encrypted assertions from the IdP. Encryption assertions are enabled by the certificate that you upload as part of the initial configuration for server-wide SAML. SAML requests and responses can be sent over HTTP or HTTPS.
 - **Site-specific SAML:** When Tableau Server is configured for site-specific SAML, Tableau Server does not support encrypted assertions from the IdP. However, all SAML requests and responses are sent over HTTPS to secure communication with the IdP. HTTP requests and responses are not supported.
- **User identity in Tableau Server for `tabcmd` users:** As described in User management requirements section above, to use `tabcmd`, you must sign in as a user defined on the server. You cannot use SAML accounts with **`tabcmd`**.
- **Using SAML SSO with Tableau Desktop:** By default, Tableau Desktop allows SP-initiated SAML authentication.

If your IdP does not support this functionality, you can disable SAML sign-in for Tableau Desktop using the following command:

```
tsm authentication saml configure --desktop-access disable
```

For more information, see `tsm authentication saml <commands>`.

- **Distributed installations:** TSM versions of Tableau Server (2018.2 and newer) use the Client File Service to share files in a multi node cluster. After you have configured SAML on the initial node in your cluster, the Client File Service will distribute certificate and key files to the other nodes.
- **Login URL:** For users to be able to sign in, your IdP must be configured with SAML Login endpoint that sends a POST request to the following URL:

```
https://<tableauserver>/wg/saml/SSO/index.html.
```

- **Logout URL:** To enable users to sign out after signing in with SAML (single logout, or SLO), your IdP must be configured with a SAML Logout endpoint that sends a POST request to the following URL:

```
https://<tableauserver>/wg/saml/SingleLogout/index.html.
```

Note: Tableau Server supports both service provider (SP)-initiated SLO and identity provider (IdP)-initiated SLO for both server-wide SAML and site-specific SAML.

- **Post-logout redirect URL:** By default, when a user signs out of Tableau Server, the sign-in page is displayed.

To display a different page after sign-out, use the `tsm authentication saml configure` command with the `-su` or `--signout-url` option.

- To specify an absolute URL, use a fully-qualified URL starting with `http://` or `https://`, as in this example:

```
tsm authentication saml configure -su https://example.com
```

- To specify a URL relative to the Tableau Server host, use a page starting with a `/` (slash):

```
tsm authentication saml configure -su /ourlogoutpage.html
```

- **Active Directory Federation Service (AD FS):** You must configure AD FS to return additional attributes for Tableau authentication with SAML. The **Name ID** and **user-name** attributes can be mapped to the same AD attribute: **SAM-Account-Name**.

For configuration information, see [Configure SAML with AD FS on Tableau Server](#).

- **AuthNContextClassRef :** AuthNContextClassRef is an optional SAML attribute that enforces validation of certain authentication "contexts" in IdP initiated flows. You can set comma-separated values for this attribute with TSM. When this attribute is set, Tableau Server validates that the SAML response contains at least one of the values listed. If the SAML response does not contain one of the configured values, authentication will be rejected, even if the user has successfully authenticated with the IdP.

Leaving this optional attribute blank will result in default behavior: any successfully authenticated SAML response will result in a user being granted a session within Tableau Server.

This value is only evaluated for server-wide SAML. If site-SAML is configured, the `AuthNContextClassRef` attribute will be ignored.

To set this value with TSM web interface, see [Configure Server-Wide SAML](#).

To set this value with tsm configuration set, use the key, `wgserver.saml.authcontexts`, to set a comma-separated list of values.

To set this value with a JSON configuration file, see [samlSettings Entity](#).

Using SAML SSO with Tableau client applications

Tableau Server users with SAML credentials can sign in to the server from Tableau Desktop or the Tableau Mobile app. For full compatibility, we recommend that the Tableau client application version matches that of the server. To connect using site-specific SAML, users must run version 10.0 or later of the Tableau client application.

Connecting to Tableau Server from Tableau Desktop or Tableau Mobile uses a service provider (SP) initiated connection.

Redirecting authenticated users back to Tableau clients

When a user signs in to Tableau Server, Tableau Server sends a SAML request (`AuthnRequest`) to the IdP, which includes the Tableau application's **RelayState** value. If the user has signed in to Tableau Server from a Tableau client such as Tableau Desktop or Tableau Mobile, it's important that the RelayState value is returned within the IdP's SAML response back to Tableau.

When the RelayState value is not returned properly in this scenario, the user is taken to their Tableau Server home page in the web browser, rather than being redirected back to the application they signed in from.

Work with your Identity Provider and internal IT team to confirm that this value will be included as part of the IdP's SAML response, and then preserved by any network appliance (such as a proxy or load balancer) that resides between your IdP and Tableau Server.

XML data requirements

As part of SAML configuration, you exchange XML metadata between Tableau Server and the IdP. This XML metadata is used to verify a user's authentication information when the user initiates the Tableau Server sign-in process.

Tableau Server and the IdP each generates its own metadata. Each set of metadata must contain the information described in the following list. If either set is missing information, errors can occur when you configure SAML or when users try to sign in.

- **HTTP POST and HTTP REDIRECT:** Tableau Server supports HTTP POST and HTTP REDIRECT requests for SAML communications. In the SAML metadata XML document that is exported by the IdP, the `Binding` attribute can be set to HTTP-POST or HTTP-REDIRECT.
- When the `Binding` attribute set to HTTP-POST, the SAML metadata that Tableau Server and the IdP each export must contain the following elements.

- The element that specifies the URL that the IdP redirects to after successful authentication. This is required in the Service Provider metadata, not the Identity Provider metadata.

```
<md:AssertionConsumerService Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Location="https://<tableau-server>/wg/saml/SSO/index.html" index="0" isDefault="true"/>
```

For Site SAML, the Location endpoint is `/samlservice/public/sp/metadata?alias=<site alias>`.

- The logout endpoint element appears in Tableau Server metadata and specifies the URL that the IdP will use for Tableau Server's logout endpoint. If this element is not in the IdP metadata, Tableau Server cannot negotiate a logout endpoint with the IdP and the SAML Logout feature will not be available within Tableau Server:

```
<md:SingleLogoutService Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Location="https://SERVER-NAME:9031/idp/slo"
```

Note: SP-initiated SLO is supported for both server-wide and site-specific SAML. However, IdP-initiated SLO is not supported.

- Verify that the metadata XML from the IdP includes a **SingleSignOnService** element, in which the binding is set to `HTTP-POST`, as in the following example:

```
<md:SingleSignOnService Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Location="https://SERVER-NAME:9031/idp/SSO.saml2"/>
```

- This element should appear in IdP metadata and specifies the URL that Tableau Server will use for the IdP's logout endpoint.

```
<md:SingleLogoutService Bind-
ing="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Loca-
tion="https://SERVER-NAME:9031/idp/slo"/>
```

- **Attribute named *username*:** You must configure the IdP to return an assertion that includes the `username` attribute in the `saml:AttributeStatement` element. The assertion's attribute type must be `xs:string` (it should *not* be typed as `xs:any`).

The following example shows what this might look like.

```
<saml:Assertion assertion-element-attributes>
  <saml:Issuer>issuer-information</saml:Issuer>
  <Signature xmlns="http://www.w3.org/2000/09/xmldsig#">
    ...
  </Signature>
  <saml:Subject>
    ...
  </saml:Subject>
  <saml:Conditions condition-attributes >
    ...
  </saml:Conditions>
  <saml:AuthnStatement authn-statement-attributes >
    ...
  </saml:AuthnStatement>

  <saml:AttributeStatement>
    <saml:Attribute Name="username" NameFormat-
t="urn:oasis:names:tc:SAML:2.0:attrname-format:basic">
      <saml:AttributeValue xmlns:x-
s="http://www.w3.org/2001/XMLSchema" xmlns:x-
si="http://www.w3.org/2001/XMLSchema-instance"
xsi:type="xs:string">
```

```
        user-name  
    </saml:AttributeValue>  
  </saml:Attribute>  
</saml:AttributeStatement>  
</saml:Assertion>
```

By default, Tableau Server will read the `username` attribute in the `AuthNResponse` returned from the IdP. However, some IdPs may return a different attribute that is intended to identify the user.

To change the SAML attribute that passes the `username` value, run the following TSM command:

```
tsm authentication saml map-assertions --user-name <USER-NAME>.
```

See [tsm authentication](#).

Configure Server-Wide SAML

Configure server-wide SAML when you want all single sign-on (SSO) users on Tableau Server to authenticate through a single SAML identity provider (IdP), or as the first step to configuring site-specific SAML in a multi-site environment.

If you have configured server-wide SAML and are ready to configure a site, see [Configure Site-Specific SAML](#).

The SAML configuration steps we provide make the following assumptions:

- You are familiar with the options for configuring SAML authentication on Tableau Server, as described in the [SAML](#) topic.
- You have verified that your environment meets the [SAML Requirements](#), and obtained the SAML certificate files described in those requirements.

Before you begin

As part of your disaster recovery plan, we recommend keeping a backup of certificate and IdP files in a safe location off of the Tableau Server. The SAML asset files that you upload to Tableau Server will be stored and distributed to other nodes by the Client File Service. However, these files are not stored in a recoverable format. See Tableau Server Client File Service.

Note: If you use the same certificate files for SSL, you could alternatively use the existing certificate location for configuring SAML, and add the IdP metadata file to that directory when you download it later in this procedure. For more information, see Using SSL certificate and key files for SAML in the SAML requirements.

If you are running Tableau Server in a cluster, then the SAML certificates, keys, and metadata file will be automatically distributed across the nodes when you enable SAML.

Use the TSM web interface

This procedure requires that you upload the SAML certificates to TSM so that they are properly stored and distributed in the server configuration. The SAML files must be available to the browser on the local computer where you are running the TSM web interface in this procedure.

If you have gathered and saved the SAML files to the Tableau Server as recommended in the previous section, then run the TSM web interface from the Tableau Server computer where you copied the files.

If you are running the TSM web interface from a different computer, then you will need to copy all SAML files locally before proceeding. As you follow the procedure below, browse to the files on the local computer to upload them to TSM.

1. Open TSM in a browser:

<https://<tsm-computer-name>:8850>. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. On the **Configuration** tab, select **User Identity & Access**, and then select the **Authentication Method** tab.

3. For **Authentication Method**, select **SAML**.
4. In the SAML section that appears, complete Step 1 in the GUI, entering the following settings (do not yet select the check box to enable SAML for the server):

- **Tableau Server return URL**—The URL that Tableau Server users will access, such as <https://tableau-server>.

Using <https://localhost> or a URL with a trailing slash (for example, http://tableau_server/) is not supported.

- **SAML entity ID**—The entity ID uniquely identifies your Tableau Server installation to the IdP.

You can enter your Tableau Server URL again here. If you plan to enable site-specific SAML later, this URL also serves as the base for each site's unique ID.

- **SAML certificate and key files**— Click **Select File** to upload each of these files.

If you are using a PKCS#8 passphrase-protected key file, you must enter the passphrase with TSM CLI:

```
tsm configuration set -k wgserver.saml.key.passphrase -v  
<passphrase>
```

After you provide the information required in Step 1 in the GUI, the **Download XML Metadata File** button in Step 2 in the GUI becomes available.

5. Now select the **Enable SAML authentication for the server** check box above Step 1 in the GUI.
6. Complete the remaining SAML settings.
 - a. For Steps 2 and 3 in the GUI, exchange metadata between Tableau Server and the IdP. (Here's where you might need to check in with the IdP's documentation.)

Select **Download XML Metadata File**, and specify the file location.

If you are configuring SAML with AD FS, you can return to Step 3: Configure AD FS to accept sign-in requests from Tableau Server of "Configure SAML with AD FS on Tableau Server."

For other IdPs, go to your IdP account to add Tableau Server to its applications (as a service provider), providing the Tableau metadata as appropriate.

Follow the instructions in the IdP's website or documentation to download the IdP's metadata. Save the .xml file to the same location that holds your SAML certificate and key files. For example:

```
C:\Program Files\Tableau\Tableau Server\SAML\idp-  
metadata.xml
```

- b. Return to the TSM web UI. For Step 4 in the GUI, enter the path to the IdP metadata file, and then click **Select File**.

- c. For Step 5 in the GUI: In some cases, you may need to change the assertion values in the Tableau Server configuration to match the assertion names that are passed by your IdP.

You can find assertion names in the IdP's SAML configuration. If different assertion names are passed from your IdP, then you must update Tableau Server to use the same assertion value.

Tip: “Assertions” are a key SAML component, and the concept of mapping assertions can be tricky at first. It might help to put this in a tabular-data context, in which the assertion (attribute) name is equivalent to a column heading in the table. You enter that “heading” name, rather than an example of a value that might appear in that column.

- d. For Step 6 in the GUI, select the Tableau applications in which you want to give users a single sign-on experience.

Note: The option to disable mobile access is ignored by devices running Tableau Mobile app version 19.225.1731 and higher. To disable SAML for devices running these versions you must disable SAML as a client login option on Tableau Server.

- e. For the SAML sign-out redirect, if your IdP supports single logout (SLO), enter the page you want to redirect users to after they sign out, relative to the path you entered for the Tableau Server return URL.
- f. (Optional) For Step 7 in the GUI, do the following:
 - Add a comma-separated value for the `AuthNContextClassRef` attribute. For more information about how this attribute is used, see SAML compatibility notes and requirements.
 - Specify a domain attribute if not sending the domain as part of the username (i.e., `domain\username`). For more information, see When running multiple domains.

7. Click **Save Pending Changes** after you've entered your configuration information.
8. Click **Pending Changes** at the top of the page:

9. Click **Apply Changes and Restart**.

Use the TSM CLI

Before you begin

Before you begin, do the following:

- Go to your IdP's website or application, and export the IdP's metadata XML file.

Confirm that the metadata XML from the IdP includes a **SingleSignOnService** element, in which the binding is set to `HTTP-POST`, as in the following example:

```
<md:SingleSignOnService Bind-  
ing="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Loca-  
tion="https://SERVER-NAME:9031/idp/SSO.saml2"/>
```

- Gather the certificate files and place them on Tableau Server.

In the Tableau Server folder, create a new folder named SAML, and place copies of the SAML certificate files in that folder. For example:

```
C:\Program Files\Tableau\Tableau Server\SAML
```

This is the recommended location because the user account that runs Tableau Server has the necessary permissions to access this folder.

Step 1: Configure return URL, SAML entity ID, and specify certificate and key files

1. Open the command prompt shell and configure the SAML settings for the server (replacing placeholder values with your environment path and file names).

```
tsm authentication saml configure --idp-entity-id https://t-  
ableau-server --idp-metadata "C:\Program Files\Tableau\Tableau  
Server\SAML\<metadata-file.xml>" --idp-return-url https://t-  
ableau-server --cert-file "C:\Program Files\Tableau\Tableau  
Server\SAML\<file.crt>" --key-file "C:\Program Files\T-  
ableau\Tableau Server\SAML\<file.key>"
```

For more information, see `tsm authentication saml configure`.

2. If you are using a PKCS#8 key that is protected with a passphrase, enter the passphrase as follows:

```
tsm configuration set -k wgserver.saml.key.passphrase -v <pass-  
phrase>
```

3. If SAML is not already enabled on Tableau Server; for example, you're configuring it for the first time, or you have disabled it, enable it now:

```
tsm authentication saml enable
```

4. Apply the changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt.

For more information, see `tsm pending-changes apply`.

Step 2: Generate Tableau Server metadata and configure the IdP

1. Run the following command to generate the required XML metadata file for Tableau server.

```
tsm authentication saml export-metadata -f <file-name.xml>
```

You can specify a file name, or omit the `-f` parameter to create a default file named `samlmetadata.xml`.

2. On your IdP's website or in its application:

- Add Tableau Server as a Service Provider.

Refer to your IdP's documentation for information about how to do this. As part of the process of configuring Tableau Server as a Service Provider, you will import the Tableau Server metadata file you generated from the `export-`

`metadata` command.

- Confirm that your IdP uses **username** as the attribute to verify users.

Step 3: Match assertions

In some cases, you may need to change the assertion values in the Tableau Server configuration to match the assertion names that are passed by your IdP.

You can find assertion names in the IdP's SAML configuration. If different assertion names are passed from your IdP, then you must update Tableau Server to use the same assertion value.

Tip: “Assertions” are a key SAML component, and the concept of mapping assertions can be tricky at first. It might help to put this in a tabular-data context, in which the assertion (attribute) name is equivalent to a column heading in the table. You enter that “heading” name, rather than an example of a value that might appear in that column.

The following table shows the default assertion values and the configuration key that stores the value.

Assertion	Default value	Key
Username	username	wgserver.saml.idpattribute.username
Display name	displayName	Tableau does not support this attribute type.
Email	email	Tableau does not support this attribute type.
Domain	(not mapped by default)	wgserver.saml.idpattribute.domain

To change a given value, run the `tsm configuration set` command with the appropriate key:value pair.

For example, to change the `username` assertion to the value, `name`, run the following commands:

```
tsm configuration set -k wgserver.saml.idpattribute.username -v name
```

```
tsm pending-changes apply
```

Alternatively, you can use the `tsm authentication saml map-assertions` command to change a given value.

For example, to set the domain assertion to a value called `domain` and specify its value as "example.myco.com," run the following commands:

```
tsm authentication saml map-assertions --domain example.myco.com
```

```
tsm pending-changes apply
```

Optional: Disable client types from using SAML

By default, both Tableau Desktop and the Tableau Mobile app allow SAML authentication.

If your IdP does not support this functionality, you can disable SAML sign-in for Tableau clients using the following commands:

```
tsm authentication saml configure --desktop-access disable
```

```
tsm authentication saml configure --mobile-access disable
```

Note: The `--mobile-access disable` option is ignored by devices running Tableau Mobile app version 19.225.1731 and higher. To disable SAML for devices running these versions you must disable SAML as a client login option on Tableau Server.

```
tsm pending-changes apply
```

Optional: Add AuthNContextClassRef value

Add a comma-separated value for the `AuthNContextClassRef` attribute. For more information about how this attribute is used, see SAML compatibility notes and requirements.

To set this attribute run the following commands:

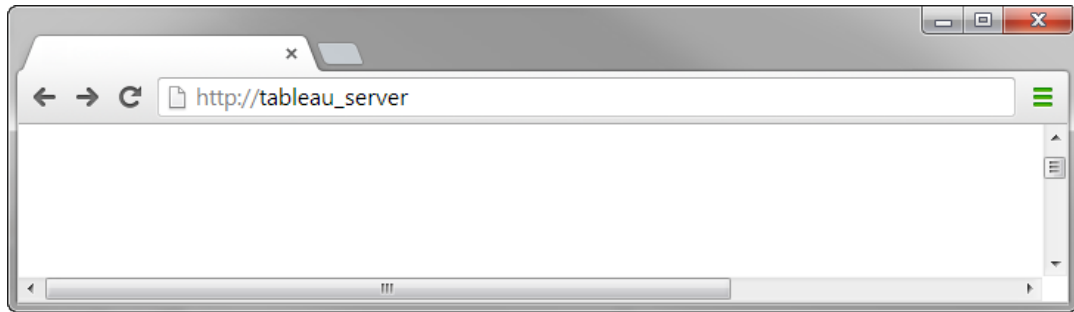

Tableau Server on Windows Help

```
tsm configuration set -k wgserver.saml.authcontexts -v <value>
```

```
tsm pending-changes apply
```

Test the configuration

1. In your web browser, open a new page or tab, and enter the Tableau Server URL.

The browser redirects you to the IdP's sign-in form.

2. Enter your single sign-on user name and password.

A screenshot of a sign-in form. At the top, there is a green checkmark icon followed by the text 'Please sign on first and we'll send you right along.' Below this, there are two input fields: 'Username' with the text 'jsmith' and 'Password' with masked characters (dots). At the bottom, there are two buttons: 'Sign On' (teal) and 'Cancel' (dark blue).

The IdP verifies your credentials and redirects you back to your Tableau Server start page.

Configure SAML with Salesforce IdP on Tableau Server

This topic provides road-map steps that describe how to configure SAML on Tableau Server with the Salesforce IdP.

This topic also explains how to enable Lightning Web Component (LWC). The LWC allows Salesforce administrators to embed a Tableau visualization within a Lightning page. When SSO is configured for Tableau Viz LWC on Tableau Server, the user experience is seamless: after the user signs into Salesforce, embedded Tableau views will work without further authentication to Tableau Server.

Enable Salesforce as a SAML Identity Provider

If you have not yet configured Salesforce as an IdP, then follow the procedure, [Enable Salesforce as a SAML Identity Provider](#), on the Salesforce Help site.

During the process to enable Salesforce as a SAML IdP, you will either specify a certificate or Salesforce will generate a self-signed certificate for use with SAML. Download this certificate (.crt file) and the associated provider metadata file (.xml). You will need these assets in the next step.

Configure SAML on Tableau Server

Using the certificate and metadata files that you downloaded in the previous step, follow the procedure in [Configure Server-Wide SAML](#).

As part of the configuration process, you will generate a SAML Entity ID and a login URL for Tableau Server. You will need these assets for the next step.

(Optional) After you have configured server-wide SAML, you can configure site-specific SAML on Tableau Server. See [Configure Site-Specific SAML](#).

Add Tableau Server as a Connected App in Salesforce

Follow the procedure, [Integrate Service Providers as Connected Apps with SAML 2.0](#), on the Salesforce Help site.

In this process, you will create a new connected app (Tableau Server). Some important details follow:

Tableau Server on Windows Help

- Select "Enable SAML"
- Enter the Entity ID and the login URL that you generated when configuring Tableau in the previous section. By default, login URL is `https://<tableauserver>/wg/saml/SSO/index.html`.
- For the IdP certificate, be sure to select the same certificate that you specified or generated when you enabled Salesforce as a SAML provider.
- To allow users to sign in to Tableau Server from your org, manage access to your connected app by assigning the appropriate profiles or permission sets.

Enable Lightning Web Component

To enable LWC for SAML SSO on Tableau Server, you must enable in-frame authentication. Before you enable LWC, upgrade to the latest maintenance release of Tableau Server. Two additional version details are important:

- If you are not running the latest maintenance release, and your users are running Chrome browsers to access Salesforce Lightning, then review the Tableau KB article, [Embedded Views Fail to Load After Updating to Chrome 80](#).
- If you are using LWC with site-specific SAML on Tableau Server, then you must be running the Tableau Server 2020.4 or later.

After you have configured SAML on Tableau Server, run the following TSM commands to enable in-frame authentication:

```
tsm configuration set -k wgserver.saml.iframe_idp.enabled -v true  
  
tsm pending-changes apply
```

Embed Tableau Views into Salesforce

After you have configured Tableau Server for SSO, you can then install the LWC in your Salesforce org and embed Tableau views. See [Embed Tableau Views into Salesforce](#).

Configure SAML for Tableau Viz Lightning Web Component

Tableau provides a Lightning Web Component (LWC) for embedding a Tableau visualization within a Salesforce Lightning page.

This topic describes how to enable a SSO experience for embedded Tableau visualizations in a Salesforce Lightning page. SSO for the Tableau Viz LWC scenario requires SAML configuration. The SAML IdP used for Tableau authentication must be either the Salesforce IdP or same IdP that is used for your Salesforce instance.

In this scenario, Salesforce administrators can drag-and-drop Tableau Viz LWC into the Lightning page to embed a visualization. Any view that is available to them on Tableau Server can be displayed in the dashboard by entering the embedded URL to the view.

When single sign-on (SSO) is configured for Tableau Viz LWC on Tableau Server, the user experience is seamless: after the user signs into Salesforce, embedded Tableau views will work without further authentication to Tableau Server.

When SSO is not configured, then users will need to reauthenticate with Tableau Server to view embedded visualizations from Tableau Server.

Requirements

- The SAML IdP used for Tableau authentication must be either the Salesforce IdP or same IdP that is used for your Salesforce instance. See [Configure SAML with Salesforce IdP on Tableau Server](#).
- SAML must be configured on Tableau Server. See [Configure Server-Wide SAML](#), or [Configure Site-Specific SAML](#).
- SAML must be configured for Salesforce.
- Install the Tableau Viz Lightning Web Component. See [Embed Tableau Views into Salesforce](#).

Configuring the authentication workflow

You may need to make additional configurations to optimize the sign-in experience for users who access Lightning with embedded Tableau views.

If a seamless authentication user experience is important, then you will need to make some additional configurations. In this context, “seamless” means that users who access the Salesforce Lightning page where Tableau Viz LWC SSO has been enabled, will not be required to perform any action to view the embedded Tableau view. In the seamless scenario, if the user

is logged into Salesforce, then embedded Tableau views will be displayed with no additional user action. This scenario is enabled by *in-frame authentication*.

For a seamless user experience you will need to enable in-frame authentication on Tableau Server and at your IdP. The sections below describe how to configure in-frame authentication.

On the other hand, there are scenarios where users are interacting with the Lightning page that will require them to click a “Sign in” button to view the embedded Tableau view. This scenario, where a user must take another action to view the embedded Tableau view, is called pop-up authentication.

Pop-up authentication is the default user experience if you do not enable in-frame authentication.

Enable in-frame authentication on Tableau Server

Before you enable in-frame authentication on Tableau Server, you must have already configured and enabled SAML on Tableau Server.

Run the following TSM commands to enable in-frame authentication:

```
tsm configuration set -k wgserver.saml.iframe_idp.enabled -v true  
  
tsm pending-changes apply
```

Note: Clickjack protection is enabled by default on Tableau Server. When you enable in-frame authentication, clickjack protection is temporarily disabled for the in-frame authentication session. You should evaluate the risk of disabling clickjack protection. See Clickjack Protection.

Tableau Server Versioning

For the best user experience, run the latest maintenance release of Tableau Server.

If you are not running the latest maintenance release, and your users are running Chrome browsers to access Salesforce Lightning, then review the Tableau KB article, [Embedded Views Fail to Load After Updating to Chrome 80](#).

Enable in-frame authentication with your SAML IdP

As described above, a seamless authentication user experience with Salesforce Mobile requires IdP support for in-frame authentication. This functionality may also be referred to as “iframe embedding” or “framing protection” at IdPs.

Salesforce safelist domains

In some cases, IdPs only allow enabling in-frame authentication by domain. In those cases, set the following Salesforce wildcard domains when you enable in-frame authentication:

```
*.force
```

```
*.visualforce
```

Salesforce IdP

Salesforce IdP supports in-frame authentication by default. You do not need to enable or configure in-frame authentication in the Salesforce configuration. However, you must run the TSM command on Tableau Server as described above.

Okta IdP

See *Embed Okta in an iframe*, in the Okta Help Center topic, [General customization options](#).

Ping IdP

See the Ping support topic, [How to Disable the "X-Frame-Options=SAMEORIGIN" Header in PingFederate](#).

OneLogin IdP

See *Framing protection*, in the OneLogin Knowledge Base article, [Account Settings for Account Owners](#).

ADFS and Azure AD IdP

Microsoft has blocked all in-frame authentication and it cannot be enabled. Instead, Microsoft only supports pop-up authentication in a second window. As a result, pop up behavior can be blocked by some browsers, which will require users to accept pop ups for the `force.com` and `visualforce.com` sites.

Salesforce Mobile App

If your users primarily interact with Lightning on the Salesforce Mobile App, then you should be aware of the following scenarios:

- The Salesforce Mobile App requires that you configure SSO/SAML to view embedded Tableau.
- The Salesforce Mobile App requires in-frame authentication. Pop-up authentication does not work. Instead, users on the Salesforce Mobile App will see the Tableau sign-in button but will not be able to sign to Tableau.
- Mobile App will not work on ADFS and Azure AD IdP.
- The Mobile App uses OAuth tokens to enable SSO. There are scenarios where the OAuth token refreshes and logs users out, requiring users to log back in. To learn more, see the Tableau KB article, [Tableau Viz Lightning Web Component On Salesforce Mobile App Prompts for Sign-in](#).
- The SSO behavior differs according to the version of Salesforce Mobile App (iOS vs Android) and the the IdP:

IdP	Mobile OS	SSO behavior
Salesforce IdP	Android	SSO works initially, but users will need to sign-in after some time.
	iOS	
External IdP	Android	SSO does not work. Users will need to manually sign-in.

		(SSO must still be configured to enable users access to embedded Tableau views).
	iOS	SSO works initially, but users will need to sign-in after some time.

Configure SAML with Azure AD IdP on Tableau Server

You can configure Azure AD as a SAML identity provider (IdP), and add Tableau Server to your supported single sign-on (SSO) applications. When you integrate Azure AD with SAML and Tableau Server, your users can sign in to Tableau Server using their standard network credentials.

Before you begin: Prerequisites

Before you can configure Tableau Server and SAML with Azure AD, your environment must have the following:

- SSL certificate encrypted using SHA-2 (256 or 512 bit) encryption, and that meets the additional requirements listed in the following sections:
 - SSL certificate requirements
 - SAML Certificate and identity provider (IdP) requirements
- If your users are signing in from a domain that's not the default domain, review SAML Requirements and User Management in Deployments with External Identity Stores to ensure the domain attribute value is set and defined to avoid any sign in issues later on.

Step 1: Verify SSL connection to Azure AD

Azure AD requires an SSL connection. If you haven't done so yet, complete the steps in Configure SSL for External HTTP Traffic to and from Tableau Server, using a certificate that meets the requirements as specified above.

Alternatively, if Tableau Server is configured to work with a reverse proxy or load balancer where SSL is being terminated (commonly referred to as SSL off-loading), then you don't need to configure external SSL.

If your organization uses Azure AD App proxy, see the section below, [Azure AD App Proxy](#).

Step 2: Configure SAML on Tableau Server

Complete the steps in Configure Server-Wide SAML through downloading the Tableau Server metadata to an XML file. At that point, return here and continue to the next section.

Step 3: Configure Azure AD claim rules

The mapping is case sensitive and requires exact spelling, so double-check your entries. The table here shows common attributes and claim mappings. You should verify the attributes with your specific Azure AD configuration.

LDAP Attribute	Outgoing Claim Type
onpremisesamaccountname	username
Given-Name	firstName Note: This is optional.
Surname	lastName Note: This is optional.
netbiosname	domain Note: This is only required if you have users signing in from a domain that's not the default domain.

In some organizations, Azure AD as a SAML IdP is used in with Active Directory as the identity store for Tableau Server. In this case, `username` is usually the `sAMAccountName` name. See Microsoft's documentation for identifying the `sAMAccountName` attribute within Azure AD to map to the `username` attribute.

Step 4: Provide Azure AD metadata to Tableau Server

1. Return to the TSM web UI, and navigate to **Configuration > User Identity & Access > Authentication Method** tab.
2. In Step 4 of the SAML configuration pane, enter the location of the XML file you exported from Azure AD, and select **Upload**.

3. Complete the remaining steps (matching assertions and specifying client type access) as specified in Configure Server-Wide SAML. Save and apply changes.
4. Perform the following steps if this isn't the first time configuring SAML:
 - a. Stop Tableau Server, open TSM CLI, and run the following commands.

```
tsm configuration set -k wgserver.saml.sha256 -v true

tsm authentication saml configure -a 7776000
```

- b. Apply the changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Azure AD App Proxy

If you're running Azure AD App Proxy in front of Tableau Server and SAML is enabled, then you'll need to make an additional configuration to Azure AD App Proxy.

Tableau Server can only accept traffic from one URL when SAML is enabled. However, by default, Azure AD App Proxy sets an external URL and an internal URL.

You must set both of these values to the same URL in your custom domain. For more information, see the Microsoft documentation, [Configure custom domains with Azure AD Application Proxy](#).

Troubleshooting

Azure AD App Proxy

In some cases, links to views render internally but fail externally when traffic is crossing an Azure AD App Proxy. The issue arises when there's a pound sign (#) in the URL and users are accessing the link with a browser. The Tableau Mobile app is able to access URLs with a pound sign.

User session timeouts appear to be ignored

When Tableau Server is configured for SAML, users might experience sign in errors because the IdP maximum authentication age setting is set to a value greater than Tableau's maximum authentication age setting. To resolve this issue, you can use the tsm configuration set option `wgserver.saml.forceauthn` to require the IdP to reauthenticate the user each time Tableau redirects the authentication request, even if the IdP session for the user is still active.

For example, when the Azure AD setting `maxInactiveTime` is greater than Tableau Server's setting `maxAuthenticationAge`, Tableau redirects the authentication request to the IdP who subsequently sends Tableau an assertion that the user is already authenticated.

However, because the user was authenticated outside of Tableau Server's `maxAuthenticationAge`, Tableau rejects the user authentication. In cases like this, you can do one or both of the following:

- Enable the `wgserver.saml.forceauthn` option to require the IdP to reauthenticate the user every time Tableau redirects the authentication request. For more information, see `wgserver.saml.forceauthn`.
- Increase Tableau Server's `maxAuthenticationAge` setting. For more information, see "a, --max-auth-age <max-auth-age>" in the tsm authentication topic.

AppID mismatch

When reviewing the `vizportal.log` file, you might see "*The intended audience doesn't match the recipient*" error.

To resolve this issue, ensure the appID matches what is sent. Azure will automatically append "SPN" to the appID when using the application ID with the app that is being used. You can change the value in the Tableau SAML settings by adding "SPN:" prefix to the application ID.

For example: SPN:myazureappid1234

Configure SAML with AD FS on Tableau Server

You can configure Active Directory Federation Services (AD FS) as a SAML identity provider, and add Tableau Server to your supported single sign-on applications. When you integrate AD FS with SAML and Tableau Server, your users can sign in to Tableau Server using their standard network credentials.

Prerequisites

Before you can configure Tableau Server and SAML with AD FS, your environment must have the following:

- A server running Microsoft Windows Server 2008 R2 (or later) with AD FS 2.0 (or later) and IIS installed.
- We recommend that you secure your AD FS server (for example, using a reverse proxy). When your AD FS server is accessible from outside your firewall, Tableau Server can redirect users to the sign in page hosted by AD FS.

- SSL certificate encrypted using SHA-2 (256 or 512 bit) encryption, and that meets the additional requirements listed in the following sections:
 - SSL certificate requirements
 - SAML Certificate and identity provider (IdP) requirements

Step 1: Verify SSL connection to AD FS

AD FS requires an SSL connection. If you haven't done so yet, complete the steps in [Configure SSL for External HTTP Traffic to and from Tableau Server](#), using a certificate that meets the requirements as specified above.

Alternatively, if Tableau Server is configured to work with a reverse proxy or load balancer where SSL is being terminated (commonly referred to as SSL off-loading), then you do not need to configure external SSL.

Step 2: Configure SAML on Tableau Server

Complete the steps in [Configure Server-Wide SAML](#) through downloading the Tableau Server metadata to an XML file. At that point, return here and continue to the next section.

Step 3: Configure AD FS to accept sign-in requests from Tableau Server

Note: These steps reflect a third-party application and are subject to change without our knowledge.

Configuring AD FS to accept Tableau Server sign-in requests is a multi-step process, starting with importing the Tableau Server XML metadata file to AD FS.

1. Do one of the following to open the **Add Relying Party Trust Wizard**:

Windows Server 2008 R2:

- a. Select **Start menu> to Administrative Tools> AD FS 2.0**.
- b. In **AD FS 2.0**, under **Trust Relationships**, right-click the **Relying Party Trusts** folder, and then click **Add Relying Party Trust**.

Windows Server 2012 R2:

- a. Open **Server Manager**, and then on the **Tools** menu, click **AD FS Management**.
 - b. In **AD FS Management**, on the **Action** menu, click **Add Relying Party Trust**.
2. In the **Add Relying Party Trust Wizard**, click **Start**.
 3. On the **Select Data Source** page, select **Import data about the relying party from a file**, and then click **Browse** to locate your Tableau Server XML metadata file. By default, this file is named **samlspmetadata.xml**.
 4. Click **Next**, and on the **Specify Display Name** page, type a name and description for the relying party trust in the **Display name** and **Notes** boxes.
 5. Click **Next** to skip the **Configure Multi-factor Authentication Now** page.
 6. Click **Next** to skip the **Choose Issuance Authorization Rules** page.
 7. Click **Next** to skip the **Ready to Add Trust** page.
 8. On the **Finish** page, select the **Open the Edit Claim Rules dialog for this relying party trust when the wizard closes** check box, and then click **Close**.

Next, you'll work in the **Edit Claim Rules** dialog, to add a rule that makes sure the assertions sent by AD FS match the assertions Tableau Server expects. At a minimum, Tableau Server needs an email address. However, including first and last names in addition to email will ensure the user names displayed in Tableau Server are the same as those in your AD account.

1. In the **Edit Claim Rules** dialog box, click **Add Rule**.
2. On the **Choose Rule Type** page, for **Claim rule template**, select **Send LDAP Attributes as Claims**, and then click **Next**.
3. On the **Configure Claim Rule** page, for **Claim rule name**, enter a name for the rule that makes sense to you.
4. For **Attribute store**, select **Active Directory**, complete the mapping as shown below, and then click **Finish**.

The mapping is case sensitive and requires exact spelling, so double-check your entries. The table here shows common attributes and claim mappings. Verify attributes with your specific Active Directory configuration.

LDAP Attribute	Outgoing Claim Type
SAM-Account-Name	Name ID
SAM-Account-Name	username
Given-Name	firstName
Surname	lastName

If you are running AD FS 2016 or later, then you must add a rule to pass through all claim values. If you are running an older version of AD FS, skip to the next procedure to export AD FS metadata.

1. Click **Add Rule**.
2. Under **Claim rule template**, choose **Pass Through or Filter an Incoming Claim**.
3. Under **Claim rule name**, enter Windows.
4. On the **Edit Rule - Windows** pop-up:
 - Under **Incoming claim type**, select **Windows account name**.
 - Select **Pass through all claim values**.
 - Click **OK**.

Now you will export AD FS metadata that you'll import to Tableau Server later. You will also make sure the metadata is configured and encoded properly for Tableau Server, and verify other AD FS requirements for your SAML configuration.

1. Export AD FS Federation metadata to an XML file, and then download the file from **`https://<adfs server name>/federationmetadata/2007-06/FederationMetadata.xml`**.
2. Open the metadata file in a text editor like Sublime Text or Notepad++, and verify that it is correctly encoded as UTF-8 without BOM.

If the file shows some other encoding type, save it from the text editor with the correct encoding.

3. Verify that AD FS uses forms-based authentication. Sign-ins are performed in a browser window, so you need AD FS to default to this type of authentication.

Edit **`c:\inetpub\adfs\ls\web.config`**, search for the tag , and move the line so it appears first in the list. Save the file so that IIS can automatically reload it.

Note: If you don't see the **`c:\inetpub\adfs\ls\web.config`** file, IIS is not installed and configured on your AD FS server.

4. (Optional) This step is required only if AD FS is configured as an IDP for site-specific SAML. This step is not required if AD FS is configured as the IDP for server-wide SAML.

Configure an additional AD FS relying party identifier. This allows your system to work around any AD FS issues with SAML logout.

Do one of the following:

Windows Server 2008 R2:

- a. In **AD FS 2.0**, right-click on the relying party you created for Tableau Server earlier, and click **Properties**.
- b. On the **Identifiers** tab, in the **Relying party identifier** box, enter **https://<tableauservername>/public/sp/metadata** and then click **Add**.

Windows Server 2012 R2:

- a. In **AD FS Management**, in the **Relying Party Trusts** list, right-click on the relying party you created for Tableau Server earlier, and click **Properties**.
- b. On the **Identifiers** tab, in the **Relying party identifier** box, enter **https://<tableauservername>/public/sp/metadata** and then click **Add**.

Note: AD FS can be used with Tableau Server for a single relying party to the same instance. AD FS cannot be used for multiple relying parties to the same instance, for example, multiple site-SAML sites or server-wide and site SAML configurations.

Step 4: Provide AD FS metadata to Tableau Server

1. Return to the TSM web UI, and navigate to **Configuration > User Identity & Access > Authentication Method** tab.
2. In Step 4 of the SAML configuration window, enter the location of the XML file you exported from AD FS, and select **Upload**.

3. Complete the remaining steps (matching assertions and specifying client type access) as specified in **Configure Server-Wide SAML**.
4. Save and apply changes.

5. Perform the following steps if this is not the first time configuring SAML:

- a. Stop Tableau Server, open TSM CLI, and run the following commands:

```
tsm configuration set -k wgserver.saml.sha256 -v true
```

```
tsm authentication saml configure -a 7776000
```

- b. Apply the changes:

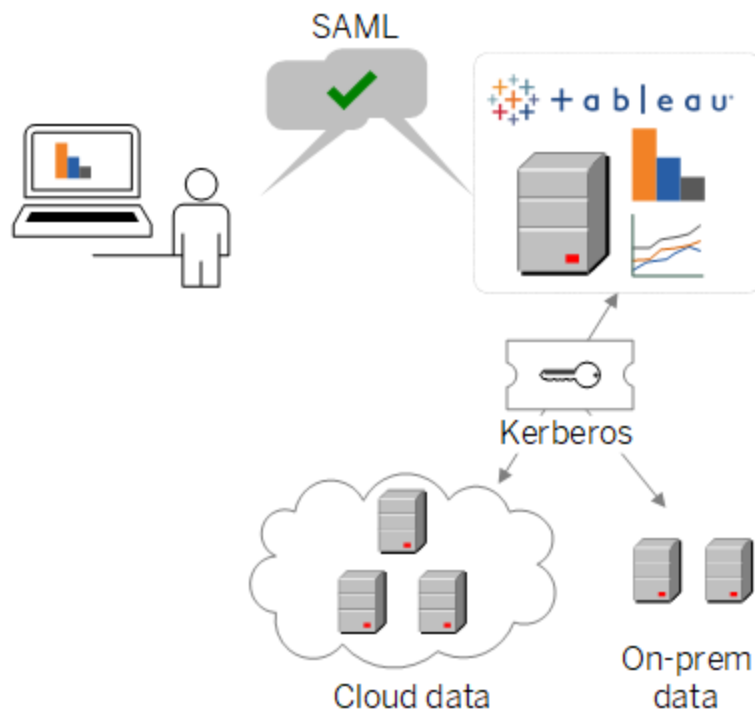

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Use SAML SSO with Kerberos Database Delegation

In a Windows Active Directory (AD) environment, you can enable SAML single sign-on (SSO) to Tableau Server, along with Kerberos database delegation. This provides authorized users direct access to Tableau Server, as well as to the underlying data defined in their published workbooks and data sources.

Overview of the process

In a typical scenario:

1. One of your Tableau analysts publishes a dashboard to Tableau Server. That dashboard contains a connection to a Hadoop cluster, for example, that is configured to accept Kerberos credentials.

Then the workbook publisher sends a link to colleagues for review.
2. When a colleague clicks the link, Tableau Server authenticates the user through the SAML SSO process. Then it looks at the user's authorization scheme, and if allowed, uses the Tableau Server keytab to access the underlying database on behalf of the user. This populates the dashboard with the Hadoop data that the user is authorized to see.

Configure Tableau Server for SAML with Kerberos

Using SAML with Kerberos works inherently when you complete the processes to enable each separately:

1. Configure Tableau Server for SAML, as described in [Configure Server-Wide SAML](#).
2. Configure Tableau Server and your underlying databases to accept Kerberos credentials, as described in [Enable Kerberos Delegation](#) and related articles.

Configure Site-Specific SAML

Use site-specific SAML in a multi-site environment when you want to enable single sign-on, and you also use multiple SAML identity providers (IdPs) or IdP applications. When you enable site SAML, you can specify the IdP or IdP application for each site, or configure some sites to use SAML and the others to use the default server-wide authentication method.

If you want all server users to use SAML and sign in through the same IdP application, see [Configure Server-Wide SAML](#).

Prerequisites for enabling site-specific SAML

Before you can enable SAML single sign-on at the site level, complete the following requirements:

- The Tableau Server identity store must be configured for local identity store.

You cannot configure site-specific SAML if Tableau Server is configured with an external identity store such as Active Directory or OpenLDAP.

- Make sure your environment and your IdP meet the general SAML Requirements.

Some features are supported only in server-wide SAML deployments, including but not limited to:

- Password-protected key files, which are not supported in site-specific SAML deployments.

- You must configure server-wide SAML before you configure site-specific SAML. You do not need to enable server-wide SAML, but site-specific SAML requires the server-wide configuration. See [Configure Server-Wide SAML](#).
- Note the location of the SAML certificate files. You will provide this when you Configure the server to support site-specific SAML.

For more information, see [Put metadata and certificate files in place](#) in the topic on configuring server-wide SAML.

- Add Tableau Server as a service provider to your IdP. You can find this information in the documentation the IdP provides.
- Confirm that the system clocks of the computer hosting the site-SAML IdP and the computer hosting Tableau Server are within 59 seconds of each other. Tableau Server does not have a configuration option to adjust the response skew (time difference) between the Tableau Server computer and the IdP.

Server-wide settings related to site-specific SAML

Return URL and entity ID: In the settings for configuring site-specific SAML, Tableau provides a site-specific return URL and entity ID based on these settings. The site-specific return URL and entity ID cannot be modified. These configurations are set by TSM as described in [Configure Server-Wide SAML](#).

Authentication age and response skew: Server-wide settings, maximum authentication age and response skew, do not apply to site-specific SAML. These configurations are hard-coded:

- The maximum authentication age refers to how long an authentication token from the IdP is valid after it is issued. The hard-coded maximum authentication age site-specific SAML is 24 days.
- The response skew is the maximum number of seconds difference between Tableau Server time and the time of the assertion creation (based on the IdP server time) that still allows the message to be processed. The hard-coded site-specific value for this is 59 seconds.

Username: Required. In addition to the server-wide SAML configuration attribute, the site-specific SAML configuration attribute must be set to "username."

Note: For site-specific SAML to operate successfully with a server-wide SAML default, the username attribute configured for server-wide SAML with the `wgserver.saml.idpattribute.username` configuration key must be "username". The IdP used for server-wide SAML must deliver the username in an attribute named "username."

5 Match attributes

Match the attribute names (assertions) in the IdP's SAML configuration to the corresponding attribute names on Tableau Server. Click Test Connection to fetch available attributes.

Tableau Server Attribute	Identity Provider (IdP) Assertion Name
Username or Email Enter the username or email address attribute that the IdP sends during the authentication process. This must match the attribute name in Tableau	username
Display Name Enter an assertion name for either the first name and last name, or for the full name, depending on how the IdP stores this information. Tableau Server uses these attributes to set the display name.	<div> <input checked="" type="radio"/> First name <input type="radio"/> Last name <input type="radio"/> Full name </div> <div> <input type="text" value="firstName"/> <input type="text" value="lastName"/> <input type="text" value="FullName"/> </div>

Apply

HTTP POST and HTTP REDIRECT: For site-specific SAML, Tableau Server supports HTTP-POST, HTTP-REDIRECT, and HTTP-POST-SimpleSign.

Configure the server to support site-specific SAML

After you complete the prerequisites listed above, you can run the following commands to configure the server to support site-specific SAML.

1. Configure Server-Wide SAML. At a minimum, you must run the following TSM command (if you have already configured server-wide SAML, skip to Step 2):

```
tsm authentication saml configure --idp-entity-id <tableau-server-entity-id> --idp-return-url <tableau-server-return-url>
```

```
--cert-file <path-to-saml-certificate.crt> --key-file <path-to-saml-keyfile.key>
```

2. Enable site SAML. Run the following commands:

```
tsm authentication sitesaml enable
```

```
tsm pending-changes apply
```

About the commands

The `sitesaml enable` command exposes the **Authentication** tab on each site's **Settings** page in the Tableau Server web UI. After you configure the server to support site SAML, you can continue to Configure SAML for a site to work through the settings on the **Authentication** tab.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

If you want to review the commands and settings that will be carried out when you run `pending-changes apply`, you can run the following command first:

```
tsm pending-changes list --config-only
```

Configure SAML for a site

This section takes you through the configuration steps that appear on the **Authentication** page in the Tableau Server web UI. In a self-hosted Tableau Server installation, this page appears only when support for site-specific SAML is enabled at the server level. It is enabled by default in Tableau Cloud.

Note: To complete this process, you will also need the documentation your IdP provides. Look for topics that refer to configuring or defining a service provider for a SAML connection, or adding an application.

Step 1: Export metadata from Tableau

To create the SAML connection between Tableau Server and your IdP, you need to exchange required metadata between the two services. To get metadata from Tableau Server, do either of the following steps. See the IdP's SAML configuration documentation to confirm the correct option.

- Select **Export metadata** to download an XML file that contains the Tableau Server SAML entity ID, Assertion Consumer Service (ACS) URL, and X.509 certificate.

The entity ID is site-specific, and based on the server-wide entity ID that you specified when you enabled site SAML on the server. For example, if you specified `https://tableau_server`, you might see the following entity ID for the site:

```
https://tableau_server-  
/samlservice/public/sp/metadata?alias=48957410-9396-430a-967c-  
75bdb6e002a0
```

You cannot modify the site-specific entity ID or ACS URL that Tableau generates.

- Select **Download signing and encryption certificate** if your IdP expects the required information in a different way. For example, if it wants you to enter the Tableau Server entity ID, ACS URL, and X.509 certificate in separate locations.

The following image has been edited to show that these settings are the same in

Tableau Cloud and Tableau Server.

1 Export metadata from Tableau Online| Server

Select an option for obtaining metadata required by the Identity Provider (IdP):

- Export an XML file that contains the metadata.

or

- Copy the Tableau Online entity ID and ACS URL individually, and download the X.509 certificate and save it as a CER file.

Tableau Online entity ID

Assertion Consumer Service URL (ACS)

Step 2 and Step 3: External steps

For Step 2, to import the metadata you exported in step 1, sign in to your IdP account, and use the instructions provided by the IdP's documentation to submit the Tableau Server metadata.

For Step 3, the IdP's documentation will guide you also in how to provide metadata to a service provider. It will instruct you to download a metadata file, or it will display XML code. If it displays XML code, copy and paste the code into a new text file, and save the file with a .xml extension.

Step 4: Import IdP metadata to the Tableau site

On the **Authentication** page in Tableau Server, import the metadata file that you downloaded from the IdP or configured manually from XML it provided.

Step 5: Match attributes

Attributes contain authentication, authorization, and other information about a user. In the **Identity Provider (IdP) Assertion Name** column, provide the attributes that contain the information Tableau Server requires.

- **Username or Email:** (Required) Enter the name of the attribute that stores user names or email addresses.
- **Display name:** (Optional) Some IdPs use separate attributes for first and last names, and others store the full name in one attribute. If you're using SAML with local authentication, the display name attribute isn't synchronized with the SAML IdP.

Select the button that corresponds to the way your IdP stores the names. For example, if the IdP combines first and last name in one attribute, select **Display name**, and then enter the attribute name.

5 Match attributes

Match the attribute names (assertions) in the IdP's SAML configuration to the corresponding attribute names on Tableau Server. Click Test Connection to fetch available attributes.

Tableau Server Attribute	Identity Provider (IdP) Assertion Name
Username or Email Enter the username or email address attribute that the IdP sends during the authentication process. This must match the attribute name in Tableau	<input type="text" value="NameID"/>
Display Name Enter an assertion name for either the first name and last name, or for the full name, depending on how the IdP stores this information. Tableau Server uses these attributes to set the display name.	<div> <input checked="" type="radio"/> First name <input type="text" value="firstName"/> </div> <div> <input checked="" type="radio"/> Last name <input type="text" value="lastName"/> </div> <div> <input type="radio"/> Full name <input type="text" value="FullName"/> </div>

Step 6: Manage users

Select existing Tableau Server users, or add new users you want to approve for single sign-on.

When you add or import users, you also specify their authentication type. On the Users page, you can change users' authentication type any time after adding them.

For more information, see [Add Users to a Site or Import Users and Set the User Authentication Type for SAML](#).

Important: Users that authenticate with site-specific SAML can belong only to one site. If a user needs to access multiple sites, set their authentication type to the server default. Depending on how site-specific SAML was configured by the server administrator, the server default is either local authentication or server-wide SAML.

Step 7: Troubleshooting

Start with the troubleshooting steps suggested on the Authentication page. If those steps do not resolve the issues, see [Troubleshoot SAML](#).

Update SAML Certificate

After you have configured SAML authentication, you may need to periodically update the certificate. In some cases, you may need to change the certificate for operational changes in your IT environment. In either case, you must use TSM or the Site Authentication page to update the SAML certificate that has already been configured.

Below are the steps to update the certificate and key files for server-wide and site-specific SAML implementations.

Update certificate for server-wide SAML

To change or update the certificate (and the corresponding key file if required) for server-wide SAML, follow the steps below:

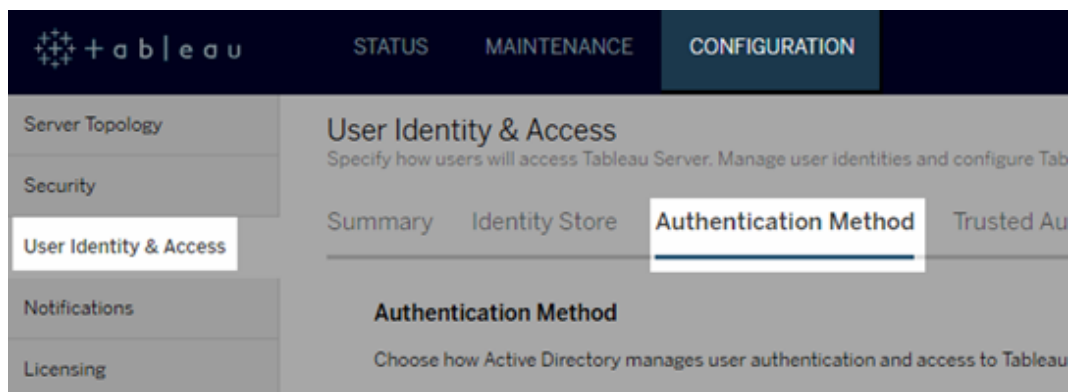

1. Open TSM in a browser:

<https://<tsm-computer-name>:8850>. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Stop Tableau Server.

You can do this either from the TSM web UI, by clicking **Tableau Server is running**, and selecting **Stop Tableau Server**, or from the command line, using the `tsm stop` command.

3. On the **Configuration** tab, select **User Identity & Access**, and then select the **Authentication Method** tab.

4. For **Authentication Method**, select **SAML**.
5. Complete Step 1 - Step 4 in the GUI to update the SAML certificate file and exchange metadata between Tableau Server and your IdP.

The screenshot shows a configuration page for SAML authentication. It is divided into four steps:

- Step 1:** Provide the location for the following SAML attributes and files.
 - Tableau Server return URL: Required
 - SAML entity ID: Required
 - SAML certificate file: Select File
 - SAML key file: Select File
- Step 2:** Download XML metadata file, and register it with your IdP.
 - Download XML Metadata File
- Step 3:** Go to your IdP's website or application and add Tableau Server as a Service Provider. Then export your IdP's metadata XML file.
- Step 4:** Upload your IdP's metadata XML file.
 - SAML IdP metadata file: Select File

6. Click **Save Pending Changes** after you've entered your configuration information.
7. Click **Pending Changes** at the top of the page:

8. Click **Apply Changes and Restart**.

After you change the certificate, you must run `tsm pending-changes apply` to restart Tableau Server services. We also recommend restarting any other services on the computer that use the SAML certificate. If you are changing a root certificate on the operating system, you must reboot the computer.

Update certificate for site-specific SAML

The certificate used for Tableau site metadata is provided by Tableau and not configurable. To update the certificate for site-specific SAML, you must upload a new certificate to your IdP and re-exchange the metadata with Tableau Server.

1. Sign in to the site as a server or site administrator, and select **Settings > Authentication**.
2. Under Authentication types, select **Edit connection** to expand the UI.
3. Open a new tab or window, and sign in to your IdP account.

4. Use the instructions provided by the IdP's documentation to upload a new SAML certificate.
5. Download the new XML metadata file to provide to Tableau Server.
6. Return to the **Authentication** page in Tableau Server, and in Step 4 of the UI, import the metadata file that you downloaded from the IdP.
7. Click the **Apply** button.

Troubleshoot SAML

This topic provides information about resolving issues that can occur when you configure SAML authentication.

SAML and Enable Automatic Logon

If you are using SAML and if Tableau Server is also configured to use Active Directory, do not also select **Enable automatic logon**. **Enable automatic logon** and SAML cannot both be used on the same server installation.

HTTP status 500 error when configuring SAML

Under some circumstances you might get an HTTP status 500 error and see the following error after enabling SAML and navigating to the Tableau Server URL in a browser:

```
org.opensaml.saml2.metadata.provider.MetadataProviderException:  
User specified binding is not supported by the Identity Provider  
using profile urn:oasis:names:tc:SAML:2.0:profiles:SSO:browser
```

To help resolve this error, make sure of the following:

- The IdP URL for the SSO profile specified in the SAML tab is correct.
- The IdP URL for the SSO profile provided while creating the service provider in the IdP is correct.

Tableau Server on Windows Help

- The IdP is configured to use HTTP-POST requests. (Redirect and SOAP are not supported.)

If any of these settings were not correct, make appropriate updates and then perform the SAML configuration steps again, starting with generating and exporting the XML metadata document from Tableau Server.

If these settings are correct, but you still see the error, examine the metadata XML that is produced by Tableau Server and by the IdP, as described in SAML Requirements.

Signing in from the command line

SAML is not used for authentication when you sign in to Tableau Server using `tabcmd` or the [Tableau Data Extract command line utility](#) (provided with Tableau Desktop), even if Tableau Server is configured to use SAML. These tools require the authentication configured when Tableau Server was originally installed (either local authentication or AD).

Login fails: Failed to find the user

Login fails with the following message:

```
>Login failure: Identity Provider authentication successful for user  
<username from IdP>. Failed to find the user in Tableau Server.
```

This error typically means that there is a mismatch between the usernames stored in Tableau Server and provided by the IdP. To fix this, make sure that they match. For example, if Jane Smith's username is stored in the IdP as `jsmith` it must be stored in Tableau Server as `jsmith`.

Login fails: SSL offloading

Logon fails with the following message:

```
Unable to Sign In - Invalid username or password.
```

Additionally, the vizportal logs (set to `debug` mode) contain the following message:

```
DEBUG com.tableau.core.util.RemoteIP - Found header null in X-
FORWARDED-PROTO
```

Note: To log SAML-related events, `vizportal.log.level` must be set to `debug`. For more information, see [Change Logging Levels](#).

This combination of messages indicates a misconfiguration of an external proxy server that is offloading SSL for the connection to Tableau Server. To resolve this issue, see the KB article, ["Unable to Sign In" and "Invalid username or password" Error With SAML After Upgrading](#).

SAML error log

SAML authentication takes place outside Tableau Server, so troubleshooting authentication issues can be difficult. However, login attempts are logged by Tableau Server. You can create a snapshot of log files and use them to troubleshoot problems. For more information, see [Log File Snapshots \(Archive Logs\)](#).

Note: To log SAML-related events, `vizportal.log.level` must be set to `debug`. For more information, see [Change Logging Levels](#).

Check for SAML errors in the following files in the unzipped log file snapshot:

```
\vizportal\vizportal-<n>.log
```

The application process (`vizportal.exe`) handles authentication, so SAML responses are logged by that process.

Trailing slash

On the SAML tab, confirm that the **Tableau Server return URL** does not end with a trailing slash

Correct: **`http://tableau_server`**

Incorrect: `http://tableau_server/`

Confirm connectivity

Confirm that the Tableau Server you are configuring has either a route-able IP address or a NAT at the firewall that allows two-way traffic directly to the server.

You can test your connectivity by running telnet on Tableau Server and attempting to connect with the SAML IdP. For example: `C:\telnet 12.360.325.10 80`

The above test should connect you to the HTTP port (80) on the IdP and you should receive an HTTP header.

Multiple domains

On the SAML tab, confirm that the Tableau Server **Domain** attribute will detect the domain in the `domain\username` format in the SAML assertion by leaving it blank.

Correct: `<empty>`

Incorrect: `yourdomain.com`

Kerberos

Kerberos is a three-way authentication protocol that relies on the use of a trusted third-party network service called the Key Distribution Center (KDC) to verify the identity of computers and provide for secure connections between the computers through the exchange of *tickets*. These tickets provide mutual authentication between computers or services, verifying that one has permission to access the other.

Tableau Server supports Kerberos authentication in an Active Directory Kerberos environment, with authentication to Tableau Server being handled by Kerberos.

Notes:

- The Kerberos support in Tableau Server is for user authentication. It does not handle internal permissions and authorization related to Tableau Server content, such as workbooks.
- Identity pools, which is a tool designed to complement and support additional user provisioning and authentication options you might need in your organization, supports

OpenID Connect (OIDC) authentication only. For more information, see [Provision and Authenticate Users Using Identity Pools](#).

How Kerberos works

When you configure Tableau Server for Kerberos in an Active Directory (AD) environment, the AD domain controller also serves as the Kerberos Key Distribution Center (KDC) and issues Ticket Granting Tickets to the other nodes in the domain. Users authenticated by the KDC do not have to authenticate further when connecting to Tableau Server.

The following is a diagram of the authentication workflow.

- | | |
|--|---|
| 1 User logs into their Active Directory domain. | 2 The Kerberos KDC authenticates the user and sends a Ticket Granting Ticket (TGT) to the user's computer. |
| 3 The user connects to Tableau Server in Tableau Desktop or in a web browser. | 4 Tableau Server authenticates the user. |

Kerberos Requirements

You can configure Kerberos authentication for Tableau Server running in Active Directory environments.

General requirements

- **External Load Balancer/Proxy Server:** If you are going to use Tableau Server with Kerberos in an environment that has external load balancers (ELBs) or proxy server, you need to set these up before you configure Kerberos in the Tableau Server Configuration utility. See [Configuring Proxies and Load Balancers for Tableau Server](#).
- **iOS Browser Support:** An iOS user can use Kerberos authentication with mobile Safari if a Configuration Profile specifying the user's Kerberos identity is installed. See [Configuring an iOS Device for Kerberos Support](#) in the Tableau Mobile Help. For more information about browser support for Kerberos SSO, see [Tableau Client Support for Kerberos SSO](#).
- Tableau Server supports constrained delegation for authentication to data sources. In this scenario, the Tableau data access account is specifically granted rights to the target database SPNs. Unconstrained delegation is not supported.
- The supported data sources (SQL Server, MSAS, PostgreSQL, Hive/Impala, and Teradata) must be configured for Kerberos authentication.
- A keytab file that is configured with the service provider name for the Tableau Server for user authentication. For more information, see [Understanding Keytab Requirements](#).
- Beginning in Tableau Server 2021.2.25, 2021.3.24, 2021.4.19, 2022.1.15, 2022.3.7, and 2023.1.3 (or later), ensure keytab files are created with AES-128 or AES-256 ciphers. RC4 and 3DES ciphers are no longer supported. For more information, see ["Tableau Server could not authenticate you automatically"](#) in the Tableau Knowledge Base.

Active Directory requirements

You must meet the following requirements to run Tableau Server with Kerberos in an Active Directory environment:

- Tableau Server must use Active Directory (AD) for authentication.
- The domain must be an AD 2003 or later domain for Kerberos connections to Tableau Server.
- Smart Card Support: Smart cards are supported when users sign into their workstations with a smartcard and this results in a Kerberos TGT being granted to the user from Active Directory.
- Single-Sign On (SSO): Users must be granted a Kerberos Ticket Granting Ticket (TGT) from Active Directory when they sign into their computers. This is standard behavior for domain-joined Windows computers and standard for Mac computers that use AD as their network account server. For more information on using Mac computers and Active Directory, see [Join your Mac to a network account server](#) in the Apple Knowledge Base.

Kerberos delegation

For Kerberos delegation scenarios the following are required:

- If the domain is AD 2003 or later, single domain Kerberos delegation is supported. The users, Tableau Server, and backend database must be on the same domain.
- If the domain is AD 2008, there is limited cross domain support. Users from other domains can be delegated if the following conditions are met. Tableau Server and the backend database must be on the same domain, and a two way trust is required between the domain where Tableau Server resides and the user's domain.
- If the domain is 2012 or later, full cross-domain delegation is supported. AD 2012 R2 is

preferred because it has a dialog for configuring constrained delegation, while 2012 non-R2 requires manual configuration.

Understanding Keytab Requirements

Kerberos authentication relies on credentials that are stored in specially formatted files called keytab files. You may need to generate keytab files for your Tableau Server deployment. This topic describes the keytab files that Tableau Server uses to access various services in a typical organization. You may need to generate keytabs for Tableau Server to integrate into the following services:

- User authentication (SSO) in Windows Active Directory
- Data source delegation
- Operating system
- Directory service

Important: Beginning in Tableau Server 2021.2.25, 2021.3.24, 2021.4.19, 2022.1.15, 2022.3.7, and 2023.1.3 (or later), ensure keytab files are created with AES-128 or AES-256 ciphers. RC4 and 3DES ciphers are no longer supported. For more information, see ["Tableau Server could not authenticate you automatically"](#) in the Tableau Knowledge Base.

If your organization includes IT professionals who handle identity, authentication, and/or security, then you should work with them to create a plan for generating appropriate keytabs for your Tableau Server deployment.

User authentication (SSO) in Windows Active Directory

If you will be using Active Directory as the identity store for Tableau Server, and you want users to authenticate with Kerberos SSO, then you will need to generate a keytab file for Tableau Server.

Tableau is running on...	Need to manually generate a keytab?
Windows in Active Directory domain	Yes
Linux in Active Directory domain	Yes

Windows or Linux in non-Active Directory environment	Kerberos SSO is not a supported scenario.
--	---

Follow these recommendations (for Windows and Linux versions of Tableau Server):

- Create a service account in your directory for Tableau Server.
- Create a keytab specifically for the Tableau Server service account. Do not reuse the keytab file that the computer account/OS uses to authenticate. You may use the same keytab for Kerberos SSO as you use for the directory authentication in the scenario above.
- You must create service principal names (SPN) in Active Directory for the Tableau Server service.
- Use the batch file in the next section to create the SPNs and the keytab file.
- After you have created the SPNs, upload the keytab file as described in [Configure Kerberos](#).

Batch file: Set SPN and create keytab in Active Directory

You can use a batch file to set the service principal names (SPN) and create a keytab file. These operations are a part of the process to enable Kerberos SSO for Tableau Server (on Windows or Linux) running in Active Directory.

In previous versions of Tableau Server (before 2018.2), the configuration script was generated from the Tableau Server Configuration utility.

To generate a configuration script, copy and paste the following batch file contents into a text file. The batch file creates service principal names (SPN) for Tableau Server and will create a keytab file for the user you specify in the file.

Follow the directions in the file contents. After you have finished customizing the file, save it as a .bat file.

This file must be run in an Active Directory domain by a Domain admin, who will be prompted for the service account password of the account you specify in the file.

The batch file uses the Windows `set`, `setspn`, and `ktpass` commands.

Note: The batch file below is self-documented. However, if you do not have experience with Kerberos and generating keytab files, we recommend that you read the Microsoft blog post, [All you need to know about Keytab files](#), before proceeding. Environmental details in your organization may require additional configuration of the `ktpass` command. For example, you must determine what to set for the `/crypto` parameter. We recommend specifying a single `/crypto` value that is required by your KDC. See the Microsoft article, [ktpass](#) for the full list of supported values for the `/crypto` parameter.

SPN and keytab batch file contents

Beginning in Tableau Server 2022.3, 2022.1.8, 2021.4.12, 2021.3.17, 2021.2.18, 2021.1.20, and 2020.4.23

```
@echo off
setlocal EnableDelayedExpansion

REM *****

REM This script generates the Service Principal Names (SPNs) and
keytab files required for
REM Kerberos SSO with Apache.
REM This script executes set, setspn, and ktpass commands included
in any Windows Server
REM Operating System from 2003 on.
REM Before running this script you must enter configuration inform-
ation for the setspn and
REM ktpass commands.
REM Elements that require your configuration information are
enclosed in as such:
```

```

REM  ! -- and --!.
REM After you customize this file, save it as a .bat file, and run
on a domain-joined
REM computer.
REM This script must be run by a Domain admin.

REM *****

REM The following set command will prompt the domain admin for cre-
dentials of the
REM Tableau Server service account.
REM This account must be a valid domain user account.
REM If the password contains a literal \" (backslash - double
quote), all backslashes
REM immediately before the double quote must be
REM duplicated when typed for the password to work, e.g. if pass-
word contains
REM \" replace with \\\", if passwords contains \\" replace with
\\\\\"

set /p adpass= "Enter password for the Tableau Server service
account."
set adpass=!adpass:="\!"

REM *****

REM The following setspn commands create the SPN in the domain.
REM More information on setspn can be found here:
REM http://technet.microsoft.com/en-us/library/cc731241\(WS.10\).aspx

REM Enter the canonical FQDN and the host names for Tableau Server
followed by the
REM Tableau Server service account name.
REM Use this syntax: HTTP/hostname domain\service_account_name.
REM The example below shows syntax for a computer named "tableau01"
in the "example.lan"

```

Tableau Server on Windows Help

```
REM domain, with service account, "tab-serv-account":
REM setspn -s HTTP/tableau01 example\tab-serv-account
REM setspn -s HTTP/tableau01.example.lan example\tab-serv-account
REM DNS and AD are not case sensitive, but the keytab files are.
Verify that host names
REM match letter case as stored in DNS.
REM Use Windows Server's DNS Manager utility to verify host name
case.

REM *****

echo Creating SPNs...
setspn -s HTTP/!--replace with canonical host name and service
account --!
setspn -s HTTP/!--replace with canonical FQDN and service account -
-!

REM *****

REM The following commands create the keytab file in the same dir-
ectory where the
REM bat file is run. More information on ktpass can be found here:
REM https://docs.microsoft.com/en-us/windows-server-
/administration/windows-commands/ktpass
REM Note: keytab files are case-sensitive.
REM The realm following the FQDN should be all uppercase.
REM Syntax is:
REM ktpass /princ HTTP/!--FQDN--!@!--Kerberos_Realm--! /pass !ad-
pass!
REM /pttype KRB5_NTPRINCIPAL /crypto !--cipher--! /out
keytabs\kerberos.keytab
REM Best practice: specify the /crypto value that is required by
your KDC.
REM Options for /crypto = {DES-CBC-CRC|DES-CBC-MD5|AES256-
SHA1|AES128-SHA1|All}
REM Do not specify /crypto All because it will result in a keytab
```

```

that contains ciphers that are not supported
REM and cause errors.
REM When using AES256-SHA1 OR AES128-SHA1, the /mapuser option must
be included
REM in the ktpass command to ensure the keytab file is mapped prop-
erly to the user. For example:
REM ktpass /princ HTTP/!--FQDN--!@!--Kerberos_Realm--! /pass !ad-
pass! /ptype KRB5_NT_PRINCIPAL /mapuser <domain\username> /crypto
AES256-SHA1 /out keytabs\kerberos.keytab
REM The following example shows the ktpass syntax with the
example.lan configuration from above:
REM ktpass /princ HTTP/!--FQDN--!@!--Kerberos_Realm--! /pass !ad-
pass! /ptype KRB5_NT_PRINCIPAL /crypto DES-CBC-CRC /out keyt-
abs\kerberos.keytab

REM *****

echo Creating Keytab files in %CD%\keytabs
mkdir keytabs
ktpass /princ HTTP/!--FQDN--!@!--Kerberos_Realm--! /pass !adpass!
/ptype KRB5_NT_PRINCIPAL /crypto DES-CBC-CRC /out keyt-
abs\kerberos.keytab

```

For earlier versions of Tableau Server

```

@echo off
setlocal EnableDelayedExpansion

REM *****

REM This script generates the Service Principal Names (SPNs) and
keytab files required for
REM Kerberos SSO with Apache.
REM This script executes set, setspn, and ktpass commands included
in any Windows Server
REM Operating System from 2003 on.

```

Tableau Server on Windows Help

```
REM Before running this script you must enter configuration information for the setspn and
REM ktpass commands.
REM Elements that require your configuration information are enclosed in as such:
REM  ! -- and --!.
REM After you customize this file, save it as a .bat file, and run on a domain-joined
REM computer.
REM This script must be run by a Domain admin.

REM *****

REM The following set command will prompt the domain admin for credentials of the
REM Tableau Server service account.
REM This account must be a valid domain user account.
REM If the password contains a literal \" (backslash - double quote), all backslashes
REM immediately before the double quote must be
REM duplicated when typed for the password to work, e.g. if password contains
REM \" replace with \\", if passwords contains \"\" replace with \\\"
REM \\\"

set /p adpass= "Enter password for the Tableau Server service account."
set adpass=!adpass:=\"=!

REM *****

REM The following setspn commands create the SPN in the domain.
REM More information on setspn can be found here:
REM http://technet.microsoft.com/en-us/library/cc731241\(WS.10\).aspx
REM Enter the canonical FQDN and the host names for Tableau Server followed by the
```

```

REM Tableau Server service account name.
REM Use this syntax: HTTP/hostname domain\service_account_name.
REM The example below shows syntax for a computer named "tableau01"
in the "example.lan"
REM domain, with service account, "tab-serv-account":
REM setspn -s HTTP/tableau01 example\tab-serv-account
REM setspn -s HTTP/tableau01.example.lan example\tab-serv-account
REM DNS and AD are not case sensitive, but the keytab files are.
Verify that host names
REM match letter case as stored in DNS.
REM Use Windows Server's DNS Manager utility to verify host name
case.

REM *****

```
your KDC.
REM Options for /crypto = {DES-CBC-CRC|DES-CBC-MD5|RC4-HMAC-
NT|AES256-SHA1|AES128-SHA1|All}
REM Specifying /crypto All will result in passwords stored with RC4
cipher, which is
REM no longer considered secure.
REM When using AES256-SHA1 OR AES128-SHA1, the /mapuser option must
be included
REM in the ktpass command to ensure the keytab file is mapped prop-
erly to the user. For example:
REM ktpass /princ HTTP/!--FQDN--!@!--Kerberos_Realm--! /pass !ad-
pass! /ptype KRB5_NT_PRINCIPAL /mapuser <domain\username> /crypto
AES256-SHA1 /out keytabs\kerberos.keytab
REM The following example shows the ktpass syntax with the
example.lan configuration from above:
REM ktpass /princ HTTP/!--FQDN--!@!--Kerberos_Realm--! /pass !ad-
pass! /ptype KRB5_NT_PRINCIPAL /crypto DES-CBC-CRC /out key-
tabs\kerberos.keytab

REM *****

echo Creating Keytab files in %CD%\keytabs
mkdir keytabs
ktpass /princ HTTP/!--FQDN--!@!--Kerberos_Realm--! /pass !adpass!
/ptype KRB5_NT_PRINCIPAL /crypto DES-CBC-CRC /out key-
tabs\kerberos.keytab
```

Operating system

If your organization uses Kerberos for authentication, then the computer where Tableau Server is running must be authenticated with the Kerberos realm in which it's running.

Tableau is running on...	Need to manually generate a keytab?
Windows in Active Directory domain	No

Linux in Active Directory domain	Yes
Windows or Linux in non-Active Directory environment	Yes

If you are running Tableau Server on Windows, and the computer is joined to the Active Directory, then you do not need to manage or generate a keytab file for the operating system.

If you are running Tableau Server on Linux in a Kerberos realm (MIT KDC or Active Directory), then you will need to generate a keytab file specifically for the computer operating system. The keytab you create for the computer should be specifically for OS authentication. Do not use the same keytab file for OS authentication that you will be using for the other services described later in this topic.

Directory service

If your organization uses a directory service, such as LDAP or Active Directory, to manage user identity, then Tableau Server requires read-only access to the directory.

Alternatively, you can configure Tableau Server to manage all accounts by installing with a local identity store. In this case, you do not need a keytab.

The following table summarizes keytab requirements:

Tableau is running on...	Directory service	Need to manually generate a keytab?
Windows in AD domain	Active Directory	No
Windows	LDAP (GSSAPI bind)	Yes
Linux	Active Directory or LDAP (GSSAPI bind)	Yes
Windows or Linux	Active Directory or LDAP (Simple bind)	No

Windows or Linux	Local identity store	No keytab required.
------------------	----------------------	---------------------

If you need to manually generate a keytab for this scenario, then you will use it for GSSAPI bind to the directory. Follow these recommendations:

- Create a service account in your directory for Tableau Server.
- Create a keytab specifically for the Tableau Server service account. Do not reuse the keytab file that the computer account/OS uses to authenticate.
- Upload the keytab file as part of the json configuration of the Tableau Server identity store. See `identityStore` Entity.

As part of your disaster recovery plan, we recommend keeping a backup of the keytab and conf files in a safe location off of the Tableau Server. The keytab and conf files that you add to Tableau Server will be stored and distributed to other nodes by the Client File Service. However, the files are not stored in a recoverable format. See [Tableau Server Client File Service](#).

Datasource delegation

You can also use Kerberos delegation to access data sources in an Active Directory. In this scenario, users can be authenticated to Tableau Server with any supported authentication mechanism (SAML, local authentication, Kerberos, etc), but can access datasources that are enabled by Kerberos.

Follow these recommendations:

- The computer account for Tableau Server (Windows or Linux) must be in Active Directory domain.
- The keytab file that you use for Kerberos delegation can be the same keytab that you use for Kerberos user authentication (SSO).

- The keytab must be mapped to the service principal for Kerberos delegation in Active Directory.
- You may use the same keytab for multiple data sources.

For more information, see the following configuration topics:

- Tableau Server on Linux: [Enable Kerberos Delegation](#)
- Tableau Server on Windows: [Enabling Kerberos Delegation](#)

Configure Kerberos

You can configure Tableau Server to use Kerberos. This allows you to provide a single sign-on (SSO) experience across all the applications in your organization. Before you configure Tableau Server for Kerberos make sure your environment meets the Kerberos Requirements.

Note: Kerberos constrained delegation for SSO to Tableau Server is not supported. (Constrained delegation for data sources is supported.) For more information, see Single-Sign On (SSO) in Kerberos Requirements.

To configure Kerberos, you must first enable Kerberos, and then specify a keytab file for user authentication. The keytab file you specify must be configured with the service provider name for the Tableau Server for user authentication. If you are using Kerberos authentication for data sources, those credentials should be included in the single keytab file that you will specify during Kerberos configuration on Tableau Server.

As part of your disaster recovery plan, we recommend keeping a backup of the keytab file in a safe location off of the Tableau Server. The keytab file that you add to Tableau Server will be stored and distributed to other nodes by the Client File Service. However, the file is not stored in a recoverable format. See Tableau Server Client File Service.

Use the TSM web interface

Tableau Server on Windows Help

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click **User Identity & Access** on the **Configuration** tab and then click **Authentication Method**.
3. Under **Authentication Method**, select **Kerberos** in the drop-down menu.
4. Under Kerberos, select **Enable Kerberos for single sign-on (SSO)**.
5. To copy the keytab file to the server, click **Select File**, and then browse to the file on your computer.

The screenshot shows the 'Authentication Method' configuration window. At the top, it says 'Specify how Active Directory manages user authentication and access to Tableau Server.' Below this is a dropdown menu with 'Kerberos' selected. Under the 'Kerberos' section, there is a checkbox labeled 'Enable Kerberos for single sign-on (SSO)' which is currently unchecked. Below the checkbox, it says 'Copy the .keytab file to Tableau Server.' and 'Keytab file' followed by a 'Select File' button. At the bottom of the window are two buttons: 'Cancel' and 'Save Pending Changes'.

6. Click **Save Pending Changes** after you've entered your configuration information.
7. Click **Pending Changes** at the top of the page:

8. Click **Apply Changes and Restart**.

Use the TSM CLI

1. If you are running Tableau Server on in a distributed cluster deployment, then you will need to manually distribute the keytab file to each node and then set the permissions. Copy the keytab file to the same directory on each node in the cluster. After you have copied the keytab file to each node and set permissions on the file, then run the following TSM commands on one node. The configuration will propagate to each node.
2. Type the following command to specify the location and name of the keytab file:

```
tsm authentication kerberos configure --keytab-file <path-to-keytab_file>
```

3. Type the following command to enable Kerberos:

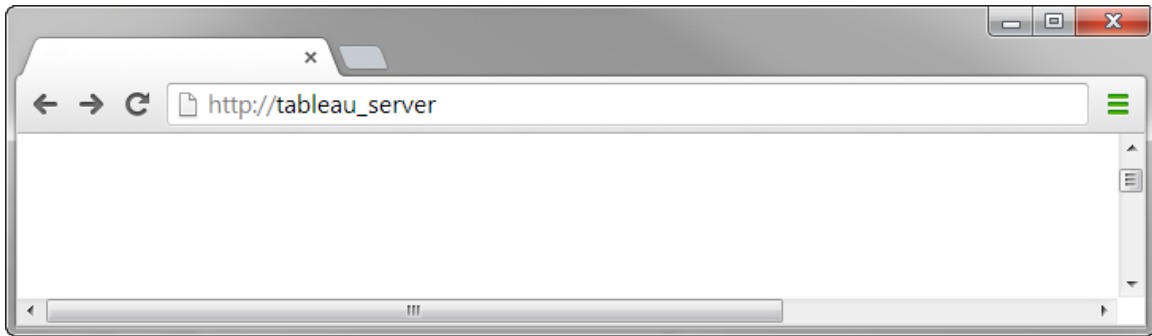

```
tsm authentication kerberos enable
```

4. Run `tsm pending-changes apply` to apply changes.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Confirm your SSO configuration

Once Tableau Server has restarted, test your Kerberos configuration from a web browser on a different computer by typing the Tableau Server name in the URL window:

You should be automatically authenticated to Tableau Server.

Tableau Client Support for Kerberos SSO

This article describes some requirements for and nuances with using Kerberos single sign-on (SSO) with Tableau Server, depending on the particular Tableau client and operating system. Tableau clients covered in this article include common web browsers, Tableau Desktop, and the Tableau Mobile app.

General browser client support

To use browser-based Kerberos Single Sign-on (SSO), the following must be true:

- Kerberos must be enabled on Tableau Server.
- The user must have a user name and password to sign in to Tableau Server.

Note: If Kerberos SSO fails, users can fall back on their user name and passwords credentials.

- The user must be authenticated to Active Directory through Kerberos on the client computer or mobile device. Specifically, this means that they have a Kerberos Ticket Granting Ticket (TGT).

Tableau Desktop and browser clients

On Windows or the Mac, you can use Kerberos SSO to sign in to Tableau Server from the following versions of Tableau Desktop or browser. Where noted, additional configuration is required.

Windows

- Tableau Desktop 10.3 or later supported.
- Internet Explorer - supported, may require configuration - see [Note 1](#)
- Chrome - supported, may require configuration -see [Note 1](#)
- Firefox - requires configuration - see [Note 2](#)
- Safari - not supported

Mac OS X

- Tableau Desktop 10.3 or newer
- Safari - supported
- Chrome - see [Note 3](#)
- Firefox - see [Note 2](#)
- Internet Explorer - not supported

Tableau Mobile app clients

On a iOS or Andoid device, you can use the following Tableau Mobile or mobile browser versions to use Kerberos authentication to Tableau Server:

iOS

- Tableau Mobile app- see [Note 4](#)
- Safari - see [Note 4](#)
- Chrome - not supported

Android - see [Note 5](#)

- Tableau Mobile app
- Chrome

Operating system and browser-specific notes

The following notes describe configuration requirements or issues with specific operating system and client combinations.

Note 1: Internet Explorer or Chrome on Windows desktop

Kerberos SSO is supported in both Internet Explorer and Chrome, but it requires configuration in **Windows Internet Options**:

1. Enable **Integrated Windows Authentication**.
2. Verify that Tableau Server URL is in the local intranet zone.

Internet Explorer can sometimes detect intranet zones and configure this setting. If it has not detected and configured the Tableau Server URL, you must manually add the URL to the local intranet zone.

To enable Integrated Windows Authentication:

1. In Windows Control Panel, open **Internet Options**.
2. On the **Advanced** tab scroll down to the **Security** section.
3. Select **Enable Integrated Windows Authentication**.
4. Click **Apply**.

To verify or add the Tableau Server URL to the local intranet zone:

1. In Windows Control Panel, open **Internet Options**.
2. On the **Security** tab, select **Local intranet**, and then click **Sites**.
3. On the **Local intranet** dialog box, click **Advanced**.

In the **Websites** field, look for the internal Tableau Server URL.

In some organizations, IT administrators will use a wildcard (*) to specify internal URLs. For example, the following URL includes all servers in the internal `example.lan` namespace in the local intranet zone:

```
https://*.example.lan
```

The following image shows a specific URL of `https://tableau.example.lan`.

4. If the Tableau Server URL or a wildcard URL is not specified in the **Websites** field, enter the Tableau Server URL in the **Add the website to the zone** field, click **Add**, and then click **OK**.

If the Tableau Server URL is already listed in **Websites**, you can simply close the dialog.

Note 2: Firefox on Windows or Mac OS X desktop

You can use Firefox with Kerberos SSO on either Windows or Mac to sign in to Tableau Server. To do this, you must complete the following steps to configure Firefox to support Kerberos:

1. In Firefox, enter `about:config` in the address bar.
2. Click **I'll be careful, I promise** when warned about changing advanced settings.
3. Enter `negotiate` in the **Search** box.

4. Double-click **network.negotiate-auth.allow-non-fqdn**, and then set the value to **true**.
5. Double-click **network.negotiate-auth.trusted-uris** and enter the Tableau Server fully qualified domain name (FQDN). For example, `tableau.example.com`.

Note 3: Chrome on Mac OS X desktop

According to Chrome documentation, Kerberos SSO works on a Mac when you launch Chrome from a terminal window with the following command:

```
open -a "Google Chrome.app" --args --auth-server-whitelist="tableauserver.example.com"
```

where `tableauserver.example.com` is the URL for Tableau Server in your environment.

However, we have found inconsistent results in our testing. Therefore, if you want to use Kerberos SSO on a Mac, we recommend that you use Safari or Firefox. For more information, see the *Integrated Authentication* section at [HTTP authentication](#) on The Chromium Projects site.

Note: Users can still use Chrome on Mac OS X to sign in to Tableau Server, but they might be prompted to enter their user name and password (single sign-on may not work).

Note 4: Mobile Safari or Tableau Mobile on iOS

Kerberos SSO is supported if iOS is configured for Kerberos. The iOS device must have a Kerberos authentication configuration profile installed. This is usually done by an enterprise IT group. Tableau Support cannot assist with configuring iOS devices for Kerberos. See the [authentication topic](#) in the *Tableau Mobile Deployment Guide*.

Note 5: Android platform

Kerberos SSO is not supported on the Tableau Mobile app on the Android operating system. You can still use your Android device and the Tableau Mobile app or a supported mobile browser to connect to Tableau Server. In this scenario, rather than authenticating with Kerberos, users will be prompted to enter their credentials when accessing Tableau Server.

More information

- *Tableau Mobile Deployment Guide*: [Control authentication and access for Tableau Mobile](#)
- See *Web Browsers* under [Tableau Server Tech Specs](#)

Troubleshoot Kerberos

The troubleshooting suggestions in this topic are divided into issues related to single sign-on (SSO) on the server and issues with the delegated data sources.

Single sign-on to Tableau Server

In a Kerberos SSO environment, a user signing in to Tableau Server from a web browser or Tableau Desktop might see a message indicating that Tableau Server can't sign them in automatically (using single sign-on). It suggests that they provide a Tableau Server user name and password instead.

Troubleshooting sign-in errors on the client computer

- **Enter the user name and password**—To check the user's general access to Tableau Server, sign in by entering the user's name and password.

If these credentials fail, the user might not be a user on Tableau Server. For Kerberos SSO to work, the user must be able to access Tableau Server, and they must be granted a Ticket Granting Ticket (TGT) by Active Directory (as described in the **TGT** item later in this list).

- **Check other users' SSO credentials**—Try to connect with SSO to Tableau Server using other user accounts. If all users are affected, the problem might be in the Kerberos configuration.
- **Use a computer other than the server computer**—Kerberos SSO does not work when you sign in to Tableau Server on localhost. Clients must connect from a computer other than the Tableau Server computer.

- **Use a server name, not IP address**—Kerberos SSO does not work if you enter an IP address as the Tableau Server name. In addition, the server name you use to access Tableau Server must match the name used in the Kerberos configuration (see [Key table entry](#), below).
- **Confirm that the client has TGT**—The client computer must have a TGT (Ticket Granting Ticket) from the Active Directory domain. Constrained delegation, with the proxy granting a ticket, is not supported.

To confirm the client computer has a TGT, do the following:

- On Windows, open a command prompt and type the following: `klist tgt`
- On the Mac, open a terminal window and type the following: `klist`

The output should show a TGT for the user/domain trying to authenticate to Tableau Server.

The client computer might not have a TGT in the following circumstances:

- The client computer is using a VPN connection.
 - The client computer is not joined to the domain (for example, it is a non-work computer being used at work).
 - The user signed in to the computer with a local (non-domain) account.
 - The computer is a Mac that is not using Active Directory as a network account server.
- **Confirm browser version and settings**—For web browser sign-in, make sure the browser is supported for Kerberos and, if necessary, is configured correctly.
 - Internet Explorer (IE) and Chrome work “out of the box” on Windows.
 - Safari works “out of the box” on the Mac.

- Firefox requires additional configuration.

For more information, see Tableau Client Support for Kerberos SSO.

Troubleshooting sign-in errors on the server

If you cannot solve the problem from the client computer, your next steps are to troubleshoot on the computer running Tableau Server. The administrator can use the request ID to locate the sign-in attempt in the Apache logs on Tableau Server.

- **Log files**—Check the Apache error.log for an error with the exact time/date of the failed sign-in attempt.
 - In a ziplog archive, these logs are in the \httpd folder.
 - On Tableau Server, these logs are in the \data\tabsvc\logs\httpd\ folder.
- **Key table entry**—If the error.log entry includes the message, “No key table entry matching HTTP/<servername>.<domain>.<org>@”, for example:

```
[Fri Oct 24 10:58:46.087683 2014] [[:error] [pid 2104:tid 4776]
[client 10.10.1.62:56789] gss_acquire_cred() failed: Unspe-
cified GSS failure. Minor code may provide more information (,
No key table entry found matching HTTP/servername.domain.com@)
```

This error is a result of a mismatch of any of the following:

- **Tableau Server URL** - The URL used by the client computer to access the server.

This is the name that you type into Tableau Desktop or a browser address bar. It could be a shortname (`http://servername`) or a fully-qualified domain name (`http://servername.domain.com`)

- **DNS reverse lookup** for the server IP address.

This looks up a DNS name using an IP address.

At a command prompt type:

```
ping servername
```

with the IP address returned by pinging the server, do a reverse DNS lookup type:

```
nslookup <ip address>
```

The nslookup command will return network information for the IP address. In the *Non-authoritative answer* portion of the response, verify that the fully qualified domain name (FQDN) matches the following configured values:

- The Kerberos .keytab file
- Service Principal Name (SPN) for the server

For more information about configuring these values, see [Understanding Keytab Requirements](#).

Verify Kerberos configuration script

You may need to modify the ktpass command that you used to generate the keytab file for environmental variables. Review the troubleshooting steps in the Knowledge Base article, [Unable to Generate Kerberos Script Configuration for Tableau Server](#).

Data source SSO

Delegated data source access failures

Check the vizqlserver log files for "workgroup-auth-mode."

- In a ziplog archive, these logs are in the \vizqlserver\Logs folder
- On the Tableau Server, these logs are in the \data\tabsvc\vizqlserver\Logs folder

Look for "workgroup-auth-mode" in the log files. It should say "kerberos-impersonate" not "as-is".

Kerberos delegation multi-domain configuration

Tableau Server can delegate users from other Active Directory domains. If your database uses MIT Kerberos, you may need to adjust your Kerberos principal to database user mapping. Specifically, you will need to update krb5.conf with rules for each Kerberos realm that users will connect from. Use the `auth_to_local` tag in the `[realms]` section to map principal names to local user names.

For example, consider a user, `EXAMPLE\jsmith`, whose Kerberos Principal is `jsmith@EXAMPLE.LAN`. In this case, Tableau Server will specify a delegated user, `jsmith@EXAMPLE`. Tableau Server will use the Active Directory legacy domain alias as the Kerberos Realm.

The target database may already have a rule such as the following to map the user, `jsmith@EXAMPLE.LAN` to the database user, `jsmith`.

```
EXAMPLE.LAN = {  
    RULE: [1:$1@$0] (.*@EXAMPLE.LAN) s/@.*//
```

```

    DEFAULT
}

```

To support delegation, you must add another rule to map `jsmith@EXAMPLE` to a database user:

```

EXAMPLE.LAN = {
    RULE:[1:$1@$0] (. *@EXAMPLE.LAN) s/@.*//
    RULE:[1:$1@$0] (. *@EXAMPLE) s/@.*//
    DEFAULT
}

```

See the MIT Kerberos Documentation topic, [krb5.conf](#), for more information.

Cross-domain constrained delegation

In some cross-domain scenarios where the KDC is running on a Windows Server prior to Windows 2012, delegation may fail. Errors you may see include:

- SQL Server Network Interfaces: The system cannot contact a domain controller to service the authentication request. Please try again later.
- SQL Server Native Client: Cannot generate SSPI context.
- The Domain Controller returns: KRB-ERR-POLICY error with a status `STATUS_CROSSREALM_DELEGATION_FAILURE (0xc000040b)`.

Cross-domain refers to a scenario where Tableau Server is running in a different domain than the data source with different service accounts. For example:

- Tableau Server runs on DomainA with DomainA service account.
- SQL Server runs on DomainB with DomainB service account.

Traditional constrained delegation only works if both servers are in the same domain. The user can come from other domains.

If you are seeing the errors noted above, then to enable this scenario, your Active Directory administrator should remove any traditional constrained delegation which is configured on the delegating account. Removing delegation can be achieved with Active Directory

management tools or by removing the values associated with the Active Directory property, `msDS-AllowedToDelegateTo`.

If you want to preserve an existing single domain delegation alongside cross-domain delegation, you must configure both using resource-based constrained delegation.

For more information about Kerberos and constrained delegation, see the Microsoft topic, [Kerberos Constrained Delegation Overview](#).

Web authoring

There are two web authoring scenarios that do not support Kerberos delegation: "Connect to data on the web" and "Create datasource on the web." feature does not support delegation yet. Specifically, if you create a datasource that uses Kerberos on the with web authoring, the data source will use Run As service account authentication. If you want to use Kerberos delegation to create a datasource, then you must publish with Tableau Desktop. For more information on Run As service account, see [Data Access with the Run As Service Account](#).

Configure Mutual SSL Authentication

Using mutual SSL, you can provide users of Tableau Desktop, Tableau Mobile, and other approved Tableau clients a secure, direct-access experience to Tableau Server. With mutual SSL, when a client with a valid SSL certificate connects to Tableau Server, Tableau Server confirms the existence of the client certificate and authenticates the user, based on the user name in the client certificate. If the client does not have a valid SSL certificate, Tableau Server can refuse the connection.

You can also configure Tableau Server to fall back to username/password authentication if mutual SSL fails. Additionally, a user can log in using the REST API with a username and password (if one exists) whether or not fallback authentication is configured.

User authentication session time limits

When users log in with mutual SSL, the authentication session is governed by the same method that governs the Tableau Server global authentication session configuration.

For clients that connect to Tableau Server using a web browser, configuration of the global authentication session is described in the *Security Hardening Checklist*, see 10. Verify session lifetime configuration.

Sessions for connected clients (Tableau Desktop, Tableau Mobile, Tableau Prep Builder, and Bridge) use OAuth tokens to keep users logged in by re-establishing a session. By default, OAuth client tokens reset after a year. If a client token has not been used in 14 days, then it will expire. You can change these values by setting the `refresh_token.absolute_expiry_in_seconds` and `refresh_token.idle_expiry_in_seconds` options. See [tsm configuration set Options](#).

Certificate usage

Before you enable and configure mutual SSL, you must configure external SSL. External SSL authenticates Tableau Server to the client and encrypts the session using the certificate and key that is required when you configure external SSL.

For mutual SSL, an additional certificate file is required. The file is a concatenation of CA certificate files. The file type must be `.crt`. A "CA" is a *certificate authority* that issues certificates to the client computers that will connect to Tableau Server. The action of uploading the CA certificate file establishes a trust, which enables Tableau Server to authenticate the individual certificates that are presented by the client computers.

As part of your disaster recovery plan, we recommend keeping a backup of the certificate and revocation (if applicable) files in a safe location off of the Tableau Server. The certificate and revocation files that you add to Tableau Server will be stored and distributed to other nodes by the Client File Service. However, the files are not stored in a recoverable format. See [Tableau Server Client File Service](#).

RSA key and ECDSA curve sizes

The CA certificate used for mutual SSL must either have an RSA key strength of 2048, or ECDSA curve size of 256.

.You can configure Tableau Server to accept the less-secure sizes by setting the respective configuration keys:

- `ssl.client_certificate_login.min_allowed.rsa_key_size`
- `ssl.client_certificate_login.min_allowed.elliptic_curve_size`

See tsm configuration set Options.

Client certificate requirements

Users authenticating to Tableau Server with mutual SSL must present a client certificate that meets minimum security requirements.

Signing algorithm

Client certificates must use a SHA-256 or greater signing algorithm.

Tableau Server configured for mutual SSL authentication will block authentication of users with client certificates that use the SHA-1 signing algorithm.

Users who attempt to log in with SHA-1 client certificates encounter an "Unable to sign in" error, and the following error will be visible in the VizPortal logs:

```
Unsupported client certificate signature detected: [certificate Signature Algorithm name]
```

You can configure Tableau Server to accept the less secure SHA-1 signing algorithm by setting the `ssl.client_certificate_login.blocklisted_signature_algorithms` tsm configuration option.

RSA key and ECDSA curve sizes

The client certificate used for mutual SSL must either have an RSA key strength of 2048, or ECDSA curve size of 256.

Tableau Server will fail mutual authentication requests from client certificates that do not meet these requirements. You can configure Tableau Server to accept the less-secure sizes by setting the respective configuration keys:

- `ssl.client_certificate_login.min_allowed.rsa_key_size`
- `ssl.client_certificate_login.min_allowed.elliptic_curve_size`

See tsm configuration set Options.

Use the TSM web interface

1. Configure SSL for External HTTP Traffic to and from Tableau Server.
2. Open TSM in a browser:

<https://<tsm-computer-name>:8850>. For more information, see Sign in to Tableau Services Manager Web UI.
3. On the **Configuration** tab, select **User Identity & Access > Authentication Method**.
4. Under **Authentication Method**, select **Mutual SSL** in the drop-down menu.
5. Under Mutual SSL, select **Use mutual SSL and automatic sign in with client certificates**.
6. Click **Select File** and upload your certificate authority (CA) certificate file to the server.

The file (.crt) is an all-in-one file that includes certificates of CAs that are used for client authentication. The file you upload must be a concatenation of the various PEM-encoded certificate files, in order of preference.

7. Enter remaining SSL configuration information for your organization.

Username format: When Tableau Server is configured for mutual SSL, the server gets the user name from the client certificate, so it can establish a direct sign-in for the client user. The name that Tableau Server uses depends on how Tableau Server is configured for user authentication:

- Local Authentication—Tableau Server uses the UPN (User Principal Name) from the certificate.
- Active Directory (AD)—Tableau Server uses LDAP (Lightweight Directory Access Protocol) to get the user name.

Alternatively, you can set Tableau Server to use the CN (Common Name) from the client certificate.

The screenshot shows the 'Authentication Method' configuration window. At the top, it says 'Specify how Active Directory manages user authentication and access to Tableau Server.' Below this is a dropdown menu set to 'Mutual SSL'. Under the 'Mutual SSL' section, there is a description: 'Use mutual SSL for secure communication between Tableau Server and web clients and for automatic sign-in across all Tableau Server components. [Learn more](#)'. There are two checkboxes: 'Use mutual SSL and automatic sign in with client certificates' (unchecked) and 'Use username and password if SSL authentication fails' (unchecked). Below the first checkbox is a label 'SSL CA certificate file' and a 'Select File' button. Below the second checkbox is a label 'Username retrieval method' and three radio buttons: 'LDAP (Lightweight Directory Access Protocol)', 'UPN (User Principal Name)' (which is selected), and 'CN (Common Name)'. At the bottom, there are 'Cancel' and 'Save Pending Changes' buttons.

8. Click **Save Pending Changes** after you've entered your configuration information.

9. Click **Pending Changes** at the top of the page:

10. Click **Apply Changes and Restart**.

Use the TSM CLI

Step 1: Require SSL for external server communication

To configure Tableau Server to use SSL for external communication between Tableau Server and web clients, run the `external-ssl enable` command as follows, providing the names for the server certificate's `.crt` and `.key` files:

```
tsm security external-ssl enable --cert-file <file.crt> --key-file <file.key>
```

- For `--cert-file` and `--key-file`, specify the location and file name where you saved the server's CA-issued SSL certificate (.crt) and key (.key) files.
- The above command assumes the you are signed in as a user that has the **Server Administrator** site role on Tableau Server. You can instead use the `-u` and `-p` parameters to specify an administrator user and password.
- If the certificate key file requires a passphrase, include the `--passphrase` parameter and value.

Step 2: Configure and enable mutual SSL

Add mutual authentication between the server and each client, and allow for Tableau client users to be authenticated directly after the first time they provide their credentials.

1. Run the following command:

```
tsm authentication mutual-ssl configure --ca-cert <certificate-
file.crt>
```

For `--ca-cert`, specify the location and file name of the certificate authority (CA) certificate file.

The file (.crt) is an all-in-one file that includes certificates of CAs that are used for client authentication. The file you upload must be a concatenation of the various PEM-encoded certificate files, in order of preference.

2. Run the following commands to enable mutual SSL and apply the changes:

```
tsm authentication mutual-ssl enable
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart

behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Additional options for mutual SSL

You can use `mutual-ssl configure` to configure Tableau Server to support the following options.

For more information, see [tsm authentication mutual-ssl <commands>](#).

Fallback authentication

When Tableau Server is configured for mutual SSL, authentication is automatic and clients must have a valid certificate. You can configure Tableau Server to allow a fallback option, to accept user name and password authentication.

```
tsm authentication mutual-ssl configure -fb true
```

Tableau Server accepts username and password authentication from REST API clients, even if the above option is set to `false`.

User name mapping

When Tableau Server is configured for mutual SSL, the server authenticates the user directly by getting the user name from their client certificate. The name that Tableau Server uses depends on how the server is configured for user authentication:

- **Local Authentication**—uses the UPN (User Principal Name) from the certificate.
- **Active Directory (AD)**—uses LDAP (Lightweight Directory Access Protocol) to get the user name.

You can override either of these defaults to set Tableau Server to use the common name.

```
tsm authentication mutual-ssl configure -m cn
```

For more information, see [Mapping a Client Certificate to a User During Mutual Authentication](#)

Certificate Revocation List (CRL)

You might need to specify a CRL if you suspect that a private key has been compromised, or if a certificate authority (CA) did not issue a certificate properly.

```
tsm authentication mutual-ssl configure -rf <revoke-file.pem>
```

How Mutual SSL Authentication Works

Mutual (or two-way) SSL authentication provides a combination of an encrypted data stream, mutual authentication of both server and client, and direct access convenience. To use mutual SSL with Tableau Server, you need the following:

- External SSL configured on Tableau Server.
- A trusted CA-issued SSL certificate for Tableau Server. The file is a concatenation of CA certificate files. A "CA" is a *certificate authority* that issues certificates to the client computers that will connect to Tableau Server. The action of uploading the CA certificate file establishes a trust, which enables Tableau Server to authenticate the individual certificates that are presented by the client computers.
- A certificate on each client that will connect to Tableau Server.
- A Tableau Server configured to use mutual SSL.

Tableau Server and the client verify that each other has a valid certificate, and Tableau Server authenticates the user, based on the user name in the client certificate.

The following image shows a little more detail about the sequence of events that occurs with mutual SSL.

1. The user navigates to Tableau Server.
2. Tableau Server sends its SSL certificate to the client computer.
3. The client computer verifies the Tableau Server certificate.
4. The client computer sends its certificate to Tableau Server.
5. Tableau Server verifies the client certificate.
6. Tableau Server references the user name in the client certificate to authenticate the user.

Mapping a Client Certificate to a User During Mutual Authentication

When you use mutual (two-way) SSL authentication, the client presents its certificate to Tableau Server as part of the authentication process. Tableau Server then maps user information in the client certificate to a known user identity. The strategy that Tableau Server uses to perform client mapping depends on the content of your organization's client certificates.

This topic discusses the ways information in a client certificate can map to a user identity and how to change the way Tableau Server performs that mapping. To understand how the mapping happens and whether you need to change it, you must know how client certificates are structured in your organization.

- [User-name mapping options](#)
- [Change the certificate mapping](#)
- [Address user-name ambiguity in multi-domain organizations](#)

User-name mapping options

Tableau Server uses one of the following approaches to map a client certificate to a user identity:

- **Active Directory.** If Tableau Server is configured to use Active Directory for user authentication, when Tableau Server receives a client certificate, it passes the certificate to Active Directory, which maps the certificate to an Active Directory identity. Any explicit user name information in the certificate is ignored.

Note: This approach requires client certificates to be published for the user accounts in Active Directory.

- **User principal name (UPN).** A client certificate can be configured to store the user name in the user principal name field. Tableau Server reads the UPN value and maps it to a user in Active Directory or to a local user.
- **Common name (CN).** A client certificate can be configured to store the user name in the common name field of the certificate. Tableau Server reads the CN value and maps it to a user in Active Directory or to a local user.

If you configure the server for Active Directory authentication and UPN or CN user-name mapping, put the user name in one of the following formats:

`username, domain/username, or username@domain.`

For example: `jsmith, example.org/jsmith, or jsmith@example.org.`

If the server uses local authentication, the format of the name in the UPN or CN fields is not predetermined, but the name in the field must match a user name on the server.

Tableau Server on Windows Help

Change the certificate mapping

You use the `tsm authentication mutual-ssl <commands>` commands to map a client certificate to a user identity in Tableau Server:

```
tsm authentication mutual-ssl configure -m <value>
```

Possible values are `ldap` for Active Directory mapping, `upn` for UPN mapping, or `cn` for CN mapping.

When you first install and configure Tableau Server, the server sets the default user-name mapping to match the server's authentication type:

- If the server is configured to use Active Directory, it also uses Active Directory for mapping the certificate to the user identity.
- If the server is configured to use local authentication, the server gets the user-name value from the UPN field in the certificate.

If the default behavior for how Tableau Server maps a user name to an identity is not correct for your server configuration, run the following set of commands to change the mapping to use the CN value:

```
tsm authentication mutual-ssl configure -m cn
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Address user-name mapping ambiguity in multi-domain organizations

Under some circumstances, the user name in a certificate's UPN or CN field can be ambiguous. This ambiguity can lead to unexpected results when the user name is mapped to a user identity on the server.

For example, if Tableau Server is presented with a user name that does not include a domain, the server maps the user name to an identity using the default domain. This can cause an incorrect user-name mapping, potentially assigning a user a different user's identity and permissions.

This can occur particularly in environments where the following conditions apply:

- Your organization supports multiple Active Directory domains.
- The server is configured to use Active Directory authentication.
- The server is configured to use UPN or CN mapping.
- Some users have the same user name but different domains. For example, `jsmith@example.org` and `jsmith@example.com`.
- The user name in the certificate's UPN or CN fields does not include the domain as part of the user name—for example, it shows `jsmith`.

To avoid incorrect user-name mapping, make sure the client certificates include fully qualified user names with the domain, using the format `jsmith@example.org` or `example.org/jsmith`.

OpenID Connect

You can configure Tableau Server to support OpenID Connect for single sign-in (SSO).

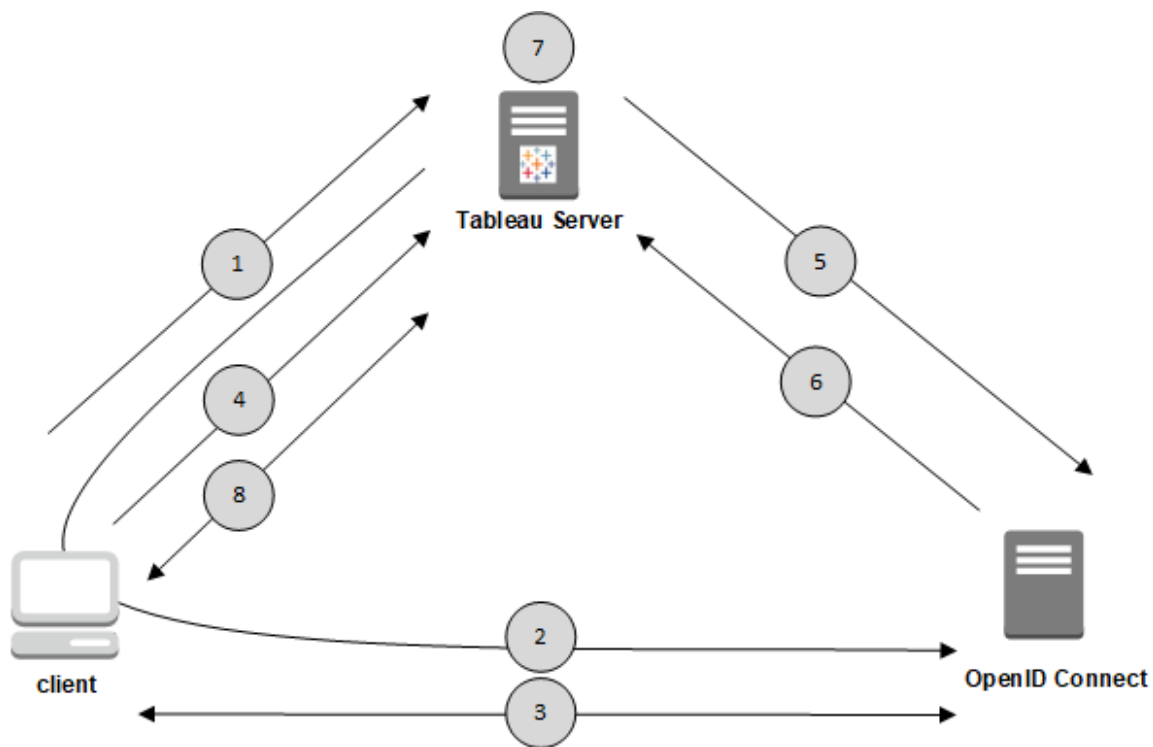

OpenID Connect is a standard authentication protocol that lets users sign in to an identity provider (IdP) such as Google. After they've successfully signed in to their IdP, they are automatically signed in to Tableau Server.

Configuring OpenID Connect involves several steps. The topics in this section provide general information about using Tableau Server with OpenID Connect, and provide a sequence for configuring the IdP and Tableau Server.

Note: Unless otherwise noted, information about OIDC authentication applies to both OIDC authentication configured in TSM during Tableau Server setup or OIDC authentication configured with **identity pools**.

Authentication overview

This section describes the OpenID Connect authentication process with Tableau Server.

Step 1: A user attempts to log in to Tableau Server from a client computer.

Step 2: Tableau Server redirects the request for authentication to the IdP gateway.

Step 3: The user is prompted for credentials and successfully authenticates to the IdP.
The IdP responds with a redirect URL back to Tableau Server. The redirect URL includes an authorization code for the user.

Step 4: The client is redirected to Tableau Server and presents the authorization code.

Step 5: Tableau Server presents the client's authorization code to the IdP along with its own client credentials. Tableau Server is also client of the IdP. This step is intended to prevent spoofing or man-in-the-middle attacks.

Step 6: The IdP returns an access token and an ID token to Tableau Server.

- **JSON Web Token (JWT) validation:** By default Tableau Server performs a validation of the IdP JWT. During discovery, Tableau Server retrieves the public keys specified by the `jwks_uri` in the IdP configuration discovery document. Tableau Server validates the ID token for expiry and then verifies the JSON web signature (JWS), the issuer (IdP), and the client ID. You can learn more about the JWT process in the OpenID documentation, [10. Signatures and Encryption](#), and the IETF proposed standard, [JSON Web Token](#). We recommend leaving JWT validation enabled, unless your IdP does not support it.
- The ID token is a set of attribute key-pairs for the user. The key-pairs are called *claims*. Here is an example IdP claim for a user:

```
"sub"                :
"7gYhRR3HiRRCaRcgvY50ubrtjGQBMJW4rXbpPFp-
g2cptHP62m2sqowM7G1LwjN5"
"email"              : "alice@tableau.com",
"email_verified"     : true,
"name"               : "Alice Adams",
"given_name"         : "Alice",
"family_name"        : "Adams",
"phone_number"       : "+359 (99) 100200305",
"profile"            : "https://tableau.com/users/alice"
```

Step 7: Tableau Server identifies the user from the IdP claims and completes the authentication request from Step 1. Tableau Server searches for the user's account record stored in the repository by matching the "sub" (subject identifier) to identify the correct user

account. If no user account is stored with the sub claim value, then Tableau Server searches for a username in the repository that matches the "email" claim from the IdP. When a username match succeeds, Tableau Server will store the corresponding sub claim to the user's record in the repository. Tableau Server can be configured to use different claims for this process. See [Requirements for Using OpenID Connect](#).

Step 8: Tableau Server authorizes the user.

How Tableau Server Works with OpenID Connect

OpenID Connect is a flexible protocol that supports many options for the information that's exchanged between a service provider (here, Tableau Server) and an IdP. The following list provides details about the Tableau Server implementation of OpenID Connect. These details can help you understand what types of information Tableau Server sends and expects, and how to configure an IdP.

- Tableau Server supports only the OpenID Authorization Code Flow as described in the [OpenID Connect final specification](#).
- Tableau Server relies on using discovery or a provider URL to retrieve the OpenID Provider metadata. Alternatively, you can host a static discovery document on Tableau Server. For more information see [Configure Tableau Server for OpenID Connect](#).
- Tableau Server supports the `client_secret_basic` and `client_secret_post` Client Authentication methods specified in the OpenID Connect specification.
- Tableau Server expects a `kid` value in the `id_token` attribute's JOSE Header. This value is matched with one of the keys found in the JWK Set document, whose URI is specified by the `jwks_uri` value in the OpenID discovery document. A `kid` value must be present even if there is only one key in the JWK Set document.
- Tableau Server does include OpenID support for the JWK `x5c` parameter or for using X.509 certificates.

- By default, Tableau Server ignores proxy settings and sends all OpenID requests directly to the IdP.

If Tableau Server is configured to use a forward proxy to connect to the internet, then you must make additional changes as described in [Configure Tableau Server for OpenID Connect](#).

Requirements for Using OpenID Connect

This topic describes the requirements to use OpenID Connect with Tableau Server.

Note: The TSM authentication configuration commands apply only to OIDC authentication configured in TSM during Tableau Server setup. To make OIDC authentication configuration changes for identity pools, you can use the [Update Authentication Configuration](#) endpoint using Tableau REST OpenAPI.

IdP account

You must have access to an identity provider (IdP) that supports the OpenID Connect (OIDC) protocol. You must also have an account with the IdP. OpenID Connect is supported by many identity providers. The OIDC protocol is an open and flexible standard, and as such, not all implementations of the standard are identical. As you configure Tableau Server for OIDC, work with your IdP.

The Google IdP implementation has been extensively tested with Tableau Server and is the model IdP for the configuration documented in these topics.

Local identity store

To use OpenID Connect on Tableau Server, one of the following must be true:

- **If configuring OIDC in TSM during Tableau Server setup**, Tableau Server must be configured to use a local identity store. The server must be configured so that you explicitly create users on the Tableau Server, rather than importing them from an external directory such as Active Directory. Managing users with an external identity store is not supported with OpenID.

- **If configuring OIDC using identity pools**, OIDC can be configured with 1) a local identity store or 2) AD or LDAP is the identity store configured in TSM during Tableau Server setup.

IdP claims: mapping users

To sign in successfully to Tableau Server, a given user must be provisioned in OpenID and then mapped to a user account on Tableau Server. OpenID uses a method that relies on *claims* to share user account attributes with other applications. Claims include user account attributes such as email, phone number, given name, etc. To understand how Tableau Server maps IdP claims to user accounts, see Authentication overview.

Tableau Server relies on the IdP claims to map user accounts from the IdP to those hosted on Tableau Server. By default, Tableau Server expects the IdP to pass the email claim. Depending on your IdP, you may need to configure Tableau Server to use a different IdP claim.

If you are using Google as an IdP, then use the default, `email` claim to map IdP identities to Tableau Server user accounts. If you are not using Google as an IdP, then work with your IdP to determine the claim for which you should configure Tableau Server.

Default: using email claim to map users

By default, the user's user name in Tableau Server must match the `email` claim in the IdP ID token. Therefore, in the default configuration, you must use email addresses (also referred to as UPN) as the username in Tableau Server. If you use Google as the IdP, the user name in Tableau Server must be the user's Gmail address (`alice@gmail.com`). Using a complete email address helps to guarantee the uniqueness of the user name in Tableau Server, even when two users have the same email but are on different email hosts.

Note: When you create a user identity in Tableau Server, you specify a user name, password, and optionally an email address. For using OpenID Connect in the default configuration, the user name (expressed as an email address) is the value that must match the user's name in the IdP. The optional email address in the Tableau Server user identity is not used for OpenID authentication.

Ignoring the domain name

You can configure Tableau to ignore the domain portion of an email address when matching the IdP `email` claim to a user account on Tableau Server. In this scenario, the `email` claim in the IdP might be `alice@example.com`, but this will match a user named `alice` in Tableau Server. Ignoring the domain name might be useful if you already have users defined in Tableau Server that match the user names portion of the `email` claim, but not the domain portions.

Important: We do not recommend ignoring the user domain name without taking precautions. Specifically, verify that user names are unique across the configured domains that you've created in your IdP.

Setting Tableau Server to ignore the user domain name has the potential to result in unintended user log on. Consider the case where your IdP has been configured for multiple domains (`example.com` and `tableau.com`). If two users with the same first name, but different user accounts (`alice@tableau.com` and `alice@example.com`) are in your organization, then the first one to complete the OpenID provisioning sequence will claim the `sub` mapping in the IdP. If the wrong user is mapped, then the other user will be unable to log on until the associated `sub` value is reset.

To configure Tableau Server to ignore domain names in user names from the IdP, set `tsm authentication openid configure --ignore-domain` to `true`. For more information, see `tsm authentication openid <commands>`.

When you change the `tsm authentication openid configure --ignore-domain` option to ignore the domain in user names, all user names in Tableau Server must have a domain name.

Using custom claims to map users

As referenced in Authentication overview, the `sub` claim is often included in IdP claims. Typically, the `sub` claim is a unique string that identifies a given user account. The benefit of using a `sub` claim is that it will not change, even if you or another admin updates other user

attributes or IdP claims (email, phone number, etc) associated with that account. By default, Tableau Server identifies and verifies OpenID users according to the `sub` claim in the IdP ID token.

The OpenID `sub` claim value must be mapped to the corresponding user in Tableau Server. Since the `sub` claim is an arbitrary string, a different claim is used to associate accounts during the first sign-in session. The first time a user signs in to Tableau Server with OpenID, Tableau will match the OpenID user account to a corresponding user account on Tableau. By default, Tableau will use the IdP claim, `email`, to identify the Tableau user. Tableau will then update that user's record with the `sub` claim from OpenID. Since the ID token always includes the `sub` claim along with other claims, on subsequent sessions, Tableau will identify that user with the `sub` claim only.

For some organizations, mapping user names with the email address is not reliable or not supported by the IdP. Beginning with Tableau Server 10.2, you can map user accounts from any arbitrary IdP claim to the Tableau Server username.

The IdP claim you are using must map exactly to a corresponding Tableau Server username. In the example below, the username is `kwilliams`.

Server Users 77

New User

Username: Username available

<input checked="" type="checkbox"/> Customer Support	<input type="text" value="Interactor"/>
<input checked="" type="checkbox"/> Default	<input type="text" value="Publisher"/>
<input type="checkbox"/> Development	

☐ Selected users are Server Administrators

To change the IdP claim that is used to map identity on Tableau Server, use the `tsm authentication openid map-claims --user-name` command. For more information, see `tsm authentication openid <commands>`.

Changing the `sub` claim

As described above, the `sub` claim is the identifier that Tableau Server uses to identify users after the initial mapping session. The `sub` claim is written to the corresponding user account in Tableau Server. If your IdP does not provide a `sub` claim, then you can specify an arbitrary claim to use instead. Like `sub`, the claim value you specify must be unique and should not change when other user claims are updated.

To specify a different IdP claim for default sub claim, use the use the `tsm authentication openid map-claims --id` command. For more information, see `tsm authentication openid <commands>`.

Where `arbitraryClaim` is the name of the IdP claim that you want to use as the replacement for the `sub` claim.

Authentication context

If your OpenID Connect IdP requires a specific authentication context, you can specify a list of essential and voluntary ACR values using the `vizportal.openid.essential_acr_values` and `vizportal.openid.voluntary_acr_values` configuration keys. For more information, see `tsm configuration set Options`.

Configure the Identity Provider for OpenID Connect

This topic provides information about configuring an identity provider (IdP) to use OpenID Connect with Tableau Server. This is one step in a multi-step process. The following topics provide information about configuring and using OpenID Connect with Tableau Server.

- OpenID Connect
- Configure the Identity Provider for OpenID Connect (you are here)
- Configure Tableau Server for OpenID Connect
- Signing In to Tableau Server Using OpenID Connect

Configure the IdP

Before you can use OpenID Connect with Tableau Server, you must have an account with an identity provider (IdP) and a project or application with the IdP. When you configure Tableau Server, you will need to be able to provide the following information:

- Provider client ID. This is the identifier that the IdP assigned to your application.
- Provider client secret. This is a token that is used by Tableau to verify the authenticity of the response from the IdP. This value is a secret and should be kept securely.
- Provider configuration URL. This is the URL at the provider's site that Tableau Server should send authentication requests to.

Redirect URL

Some IdPs will require a redirect URL for your Tableau Server. You can manually construct your URL for the IdP using the following syntax:

```
<protocol>://<host>/vizportal/api/web/v1/auth/openIdLogin
```

For example, `https://t-`

`ableau.example.com/vizportal/api/web/v1/auth/openIdLogin`.

Example IdP process

The following procedure provides an outline of the steps that you follow with the provider. As an example, the procedure discusses using Google as a provider. However, each provider has a somewhat different flow, so the specifics of the steps (and their order) might vary depending on your provider.

1. Register at the provider's developer site and sign in. For example, for Google, you can go to the Developers Console at this URL: <https://console.developers.google.com>
2. Create a new project, application, or relying party account.
3. In the developer dashboard, follow the steps for getting an OAuth 2.0 client ID and client secret. Record these values for later.

Note: Keep the client secret in a secure place.

4. On the developer site, find the URL of the endpoint that the IdP uses for OpenID Connect discovery. For example, Google uses the URL <https://accounts.google.com/.well-known/openid-configuration>.

[known/openid-configuration](#). Record this URL for later.

Alternatively, if your IdP has provided you with a static discovery document, copy that file to a local directory on the Tableau Server for later.

Configure Tableau Server for OpenID Connect

This topic describes how to configure Tableau Server to use OpenID Connect for single-sign on (SSO). This is one step in a multi-step process. The following topics provide information about configuring and using OpenID Connect with Tableau Server.

- OpenID Connect
- Configure the Identity Provider for OpenID Connect
- Configure Tableau Server for OpenID Connect (you are here)
- Signing In to Tableau Server Using OpenID Connect

Notes:

- Before you perform the steps described here, you must configure the OpenID identity provider (IdP) as described in [Configure the Identity Provider for OpenID Connect](#).
- The procedures described in this topic apply to OIDC authentication configured in TSM during Tableau Server setup and not OIDC authentication configured with identity pools. For more information about identity pools, see [Provision and Authenticate Users Using Identity Pools](#).

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click User **Identity & Access** on the **Configuration** tab and then click **Authentication Method**.
3. Under **Authentication Method**, select **OpenID Connect** in the drop-down menu.

4. Under OpenID Connect, select **Enable OpenID authentication for the server**.
5. Enter the OpenID configuration information for your organization:

Authentication Method

Specify how the identity store manages user authentication and access to Tableau Server.

OpenID Connect ▾

OpenID Connect

Use OpenID when you want users on Tableau Server to authenticate with an external OpenID Connect Identity Provider. Follow the steps below to configure OpenID.

☒ Enable OpenID authentication for the server

Step 1: Create the OpenID configuration by providing the client id, secret, and discovery URL provided by your OpenID Connect Identity Provider.

Provider client ID

Provider client secret

Provider configuration URL

Step 2: Provide the hostname and protocol of the return URL your OpenID Connect Identity Provider will use to redirect users back to Tableau Server.

Tableau Server external URL

Step 3: Copy the URL below and configure your OpenID Connect Identity Provider to redirect users to this endpoint after authenticating.

Cancel

Save Pending Changes

Note: If your provider relies on a configuration file hosted on the local computer (rather than a file hosted at a public URL), you can specify the file with the tsm authentication openid <commands>. Use the `--metadata-file <file_path>` option to specify a local IdP configuration file.

6. Click **Save Pending Changes** after you've entered your configuration information.
7. Click **Pending Changes** at the top of the page:

8. Click **Apply Changes and Restart**.

Use the TSM CLI

The procedure in this section describes how to use TSM command line interface to configure OpenID Connect. You can also use a configuration file for the initial configuration of OpenID Connect. See `openIDSettings` Entity.

1. Use the `configure` command of `tsm authentication openid <commands>` to set the following required options:

`--client-id <id>`: Specifies the provider client ID that your IdP has assigned to your application. For example, `"laakjwdlnaoiloadjkwha"`.

`--client-secret <secret>`: Specifies the provider client secret. This is a token that is used by Tableau to verify the authenticity of the response from the IdP. This value is a secret and should be kept securely. For example, `"fwahfkjaw72123="`.

`--config-url <url>` or `--metadata-file <file_path>`: Specifies location of provider configuration json file. If the provider hosts a public json discovery file, then use `--config-url`. Otherwise, specify a path on the local computer and file name for `--metadata-file` instead.

`--return-url <url>`: The URL of your server. This is typically is the public name of your server, such as `"http://example.tableau.com"`.

For example, run the command:

```
tsm authentication openid configure --client-id "laakjwdlna-  
oiloadjkwha" --client-secret "fwahfkjaw72123=" --config-url  
"https://example.com/openid-configuration" --return-url  
"http://tableau.example.com"
```

There are additional, optional configurations that you can set for Open ID Connect using either `openIDSettings` Entity or `tsm authentication openid <commands>`. In addition, if you need to configure IdP claim mapping, see `Options for openid map-claims`.

2. Type the following command to enable Open ID Connect:

```
tsm authentication openid enable
```

3. Run `tsm pending-changes apply` to apply changes.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt.

For more information, see `tsm pending-changes apply`.

Configure OpenID to work with a forward proxy

By default, Tableau Server ignores proxy settings and sends all OpenID requests directly to the IdP.

Beginning with Tableau Server 2021.2.2 and newer, if Tableau is configured to use a forward proxy to connect to the internet, then you may configure Tableau Server to use the proxy host and port settings to contact the OpenID IdP.

How you configure Tableau Server is different depending on how you have implemented forward proxy in your organization:

- Forward proxy is configured on the Windows computer where Tableau Server is running.
- Tableau Server sends all outbound traffic directly to a forward proxy server running in your organization.

Windows system proxy configuration

If your organization has configured forward proxy on each Windows computer use this method to use the system proxy configuration for OpenID on Tableau Server. Run the following commands:

```
tsm configuration set -k tomcat.useSystemProxies -v true
```

```
tsm pending-changes apply
```

Forward proxy server

Use the command, `tsm configuration set`, to make the changes.

- For HTTPS proxy hosts, use the following key-value pairs:

```
-k tomcat.https.proxyHost -v host.domain
```

```
-k tomcat.https.proxyPort -v port_number
```

For example, if your proxy server is at `https://proxy.example.lan:8443`, then run the following commands:

```
tsm configuration set -k tomcat.https.proxyHost -v proxy.example.lan
```

```
tsm configuration set -k tomcat.https.proxyPort -v 8443
```

```
tsm pending-changes apply
```

- For HTTP proxy hosts, use the following key-value pairs:

```
-k tomcat.http.proxyHost -v host.domain
```

```
-k tomcat.http.proxyPort -v port_number
```

After you have set these keys, run `tsm pending-changes apply`.

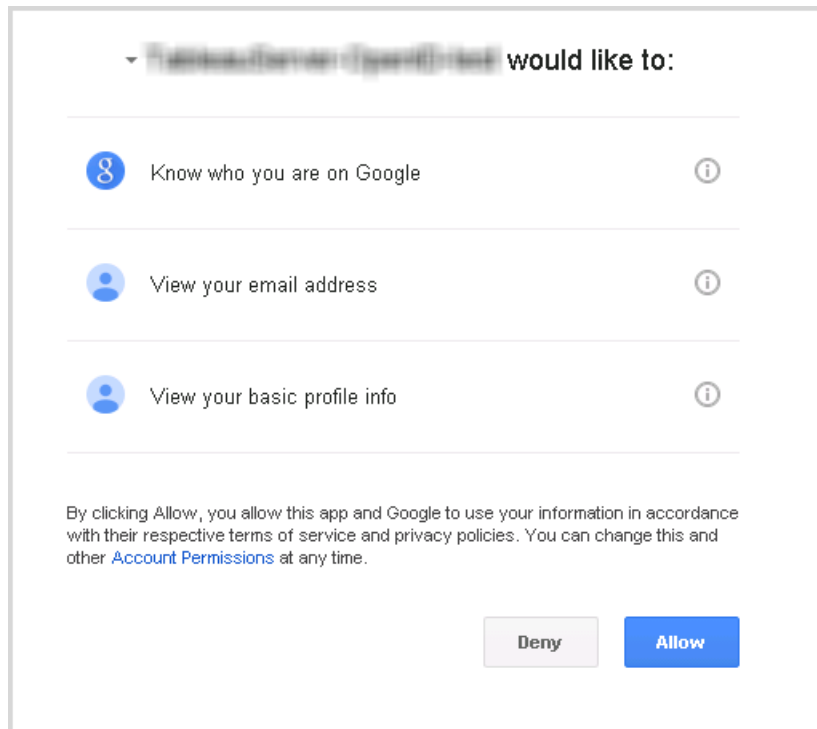

Signing In to Tableau Server Using OpenID Connect

This topic provides information about signing in to Tableau Server using OpenID Connect. The following topics provide information about configuring and using OpenID Connect with Tableau Server.

- OpenID Connect
- Configure the Identity Provider for OpenID Connect
- Configure Tableau Server for OpenID Connect
- Signing In to Tableau Server Using OpenID Connect (you are here)

Signing in using OpenID Connect

After Tableau Server has been configured to use OpenID Connect, users who access the server and aren't already signed in are redirected to the IdP site, where they are prompted to sign in. Users enter the credentials that they have with the IdP. In many cases, the user is also asked to authorize the IdP to share information with Tableau Server, as in the following example:

When a user signs in using OpenID Connect, the IdP sends a unique user identifier (known in OpenID as the sub value) as part of the information that's redirected to Tableau Server. This sub value is associated with the user's Tableau user identity.

Restricting sign-in to server administrators for command-line tools

Command-line tools for working with Tableau Server (`tabcmd`, TSM, and `tableau.com`) do not support sign-in using OpenID Connect. When OpenID Connect is enabled for the server, these tools still require sign-in using a Tableau Server username and password.

Even if users normally authenticate using OpenID Connect, each user has a Tableau Server username and password. This means that users could use command-line tools like `tabcmd`. As a security measure, you can make sure that *only* server administrators can use command-line tools. To do this, use `tsm configuration set` to set `wgserver.authentication.restricted` to `true`. When this setting is `true`, only server administrators can sign in to Tableau Server using a username and password; all other users *must* sign in to the server using a single sign-on (SSO) option like OpenID Connect. The effect is that users who are not administrators also cannot then use command-line tools. To make this change, run the following sequence of TSM commands:

```
tsm configuration set -k wgserver.authentication.restricted -v true
tsm pending-changes apply
```

OpenID Connect Authentication Request Parameters

The OpenID authentication request sent from Tableau Server passes information using a limited set of parameters, as listed in this topic. If your OpenID IdP requires parameters that are not in the following list, it is not compatible for use with Tableau Server.

- `scope`. This value specifies a profile that tells the IdP what user information claims to return. This value can be configured by a Tableau Server administrator. The default value is "openid email profile". For more information, see [Configure the scope value](#) later in this document.
- `response_type`. OpenID Connect supports multiple flows. This value tells the IdP which flow Tableau Server expects. Tableau supports only the authorization code flow, and the value is always set to "code".
- `client_id`. This value specifies the server's ID (**Provider client ID** in the Tableau Server Configuration dialog box), which lets the IdP know where the request came from. It is provided by the IdP when the service is registered. The value is configurable by a Tableau Server administrator.

- `redirect_uri`. This value specifies the URL that the IdP redirects to after the user has authenticated using OpenID Connect. The URL must include the host and protocol (for example, `http://example.tableau.com`), but Tableau provides the URL endpoint.
- `nonce`. Tableau Server generates a nonce value to verify that the client that it redirected to matches the entity that comes back from the IdP.

Configure the scope value

The `scope` value indicates to the IdP the information that Tableau Server requests about the user. By default, Tableau Server sends the value "openid profile email". This indicates that Tableau uses OpenID to authenticate (this part of the `scope` attribute value must always be included) and that Tableau Server is requesting the user profile and email information during the exchange of the user authorization code.

If this default scope is not appropriate for your scenario, you can have Tableau Server request custom information about the user. To do so, you configure the IdP with a custom profile (for example, something like "tableau-scope"). You can then configure Tableau Server to send the scope request using the name of the custom profile.

To change the scope value that Tableau Server requests, use the following TSM CLI command:

```
tsm authentication openid configure --custom-scope-name custom-  
scope-name
```

Notes:

- Tableau Server always includes "openid" as part of the scope value (even if you don't include it in the `custom_scope` setting).
- The TSM authentication configuration commands apply only to OIDC authentication configured in TSM during Tableau Server setup. To make OIDC authentication configuration changes for identity pools, you can use the [Update Authentication Configuration](#) endpoint using Tableau REST OpenAPI.

Changing IdPs in Tableau Server for OpenID Connect

This topic provides information about changing an identity provider (IdP) if you have configured Tableau Server to use OpenID Connect.

Change providers

You might decide to change the IdP that Tableau Server is configured to use. To do so, you follow the procedure that you used to configure the first IdP: establish an account, get a customer ID and secret, configure Tableau Server with that information, and provide the IdP with the redirect URL for Tableau Server. For more information, see [Configure Tableau Server for OpenID Connect](#).

Reset user identifiers

However, you also need to perform an additional step: you must clear any user identifiers (`sub` values or claims) that have already been associated with Tableau Server users. The new IdP will have different `sub` values for each user, and you must clear the existing ones so that Tableau Server can store a new `sub` value when the user signs in using the new IdP.

To clear `sub` values for users, use the `tabcmd reset_openid_sub` command. You can reset (that is, clear) `sub` values for an individual user, as in the following example:

```
tabcmd reset_openid_sub --target-username jsmith
```

You can also clear the `sub` value for all users using this command:

```
tabcmd reset_openid_sub --all
```

Note: Clearing user identifiers for members of an **identity pool** is not supported.

Troubleshoot OpenID Connect

Use the following topics to troubleshoot OpenID Connect (OIDC) issues in Tableau Server.

OpenID Connect protocol is supported by many identity providers. The OIDC protocol is an open and flexible standard, and as such, not all implementations of the standard are identical.

Most issues that administrators encounter when configuring Tableau Server for OIDC are the result of how different identity providers implement OIDC. If you encounter errors as you set up OIDC with Tableau Server, we recommend that you work with your IdP to resolve them.

Enabling enhanced OpenID logging

To efficiently troubleshoot OpenID Connect issues in Tableau Server, enable enhanced logging by setting the logging level to debug, and full logging for OpenID using the `vizportal.openid.full_server_request_logging_enabled` configuration key to `true` using these TSM commands:

```
tsm configuration set -k vizportal.log.level -v debug
```

```
tsm configuration set -k vizportal.openid.full_server_request_logging_enabled -v true
```

```
tsm pending-changes apply
```

After completing your troubleshooting, we recommend setting the values of both configuration keys back to their defaults to limit the information collected in logs and to reduce log file sizes. For details on resetting configuration keys to defaults, see [Resetting a configuration key to default](#).

Note: Enhanced logging for **identity pools** isn't supported. However, `vizportal.log.level debug` logging is supported.

Signing in from the command line

Even if Tableau Server is configured to use OpenID, it isn't used if you sign in to Tableau Server using `tabcmd`, the **REST API**, or the **Tableau Data Extract command line utility** (provided with Tableau Desktop).

Login failed

Login can fail with the following message:

Tableau Server on Windows Help

Login failure: Identity Provider authentication successful for user <username from IdP>. Failed to find the user in Tableau Server.

This error typically means that there's a mismatch between a username stored in Tableau Server and the username provided by the IdP. To fix this, make sure that they match. For example, if Jane Smith's username is stored in the IdP as `j.smith` it must be stored in Tableau Server as `j.smith` as well.

Error 69: "Unable to Sign In"

An error 69 might be returned when you attempt to sign in to Tableau Server with a web browser and receive an error, "Unable to Sign In. Sign in failed. Contact your Tableau Server administrator." The URL that returns this message is `https://example.-com/#/error/signin/69?redirectPath=%2.`

If you receive this error, check with your IDP provider to verify if the IdP is expecting `client_secret_post` instead of `client_secret_basic` (the Tableau default).

If the IdP is expecting `client_secret_post`, then you must set the `vizportal.openid.client_authentication` parameter to `client_secret_post`.

For example; If you receive this error and you have configured OIDC for the Salesforce IdP, then you must set the `vizportal.openid.client_authentication` parameter.

See tsm configuration set Options for more information.

OpenID error log

OpenID authentication takes place outside Tableau Server, so troubleshooting authentication issues can be difficult. However, sign-in attempts are logged by Tableau Server. You can create a snapshot of log files and use them to troubleshoot problems. For more information, see Tableau Server Logs and Log File Locations.

Note: To log OpenID-related events, `vizportal.log.level` must be set to debug with tsm configuration set Options.

Check for OpenID errors in the following files in the unzipped log file snapshot:

```
\vizportal\vizportal-<n>.log
```

User not found

An error "user not found" might be returned if the "sub" claims have changed after initial logins of users. You can verify this issue if you see the following in the vizportal logs: `Possible conflicting or stale account: <username> A different user already owns this account.`

If you continue to see this issue, reset the "sub" claims for that user or for all users on Tableau Server. For more information, see [Reset user identifiers](#).

Trusted Authentication

When you embed Tableau Server views into web pages, everyone who visits the page must be a licensed user on Tableau Server. When users visit the page they are prompted to sign in to Tableau Server before they can see the view. If you already have a way of authenticating users on the webpage or within your web application, you can avoid this prompt and save your users from having to sign in twice by setting up trusted authentication.

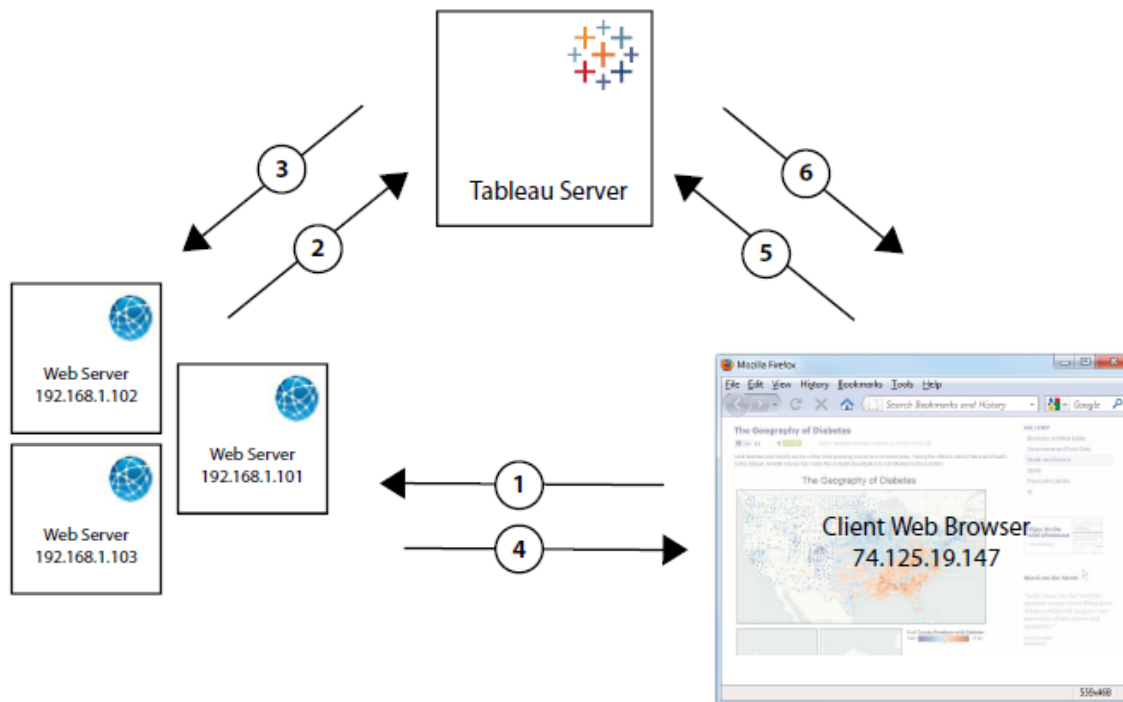

Trusted authentication simply means that you have set up a trusted relationship between Tableau Server and one or more web servers. When Tableau Server receives requests from these trusted web servers it assumes that your web server has handled whatever authentication is necessary.

If your web server uses SSPI (Security Support Provider Interface), you do not need to set up trusted authentication. You can embed views and your users will have secure access to them as long as they are licensed Tableau Server users and members of your Active Directory.

Note: Client browsers must be configured to [allow third-party cookies](#) if you want to use trusted authentication with embedded views.

How Trusted Authentication Works

The diagram below describes how trusted authentication works between the client's web browser, your web server(s) and Tableau Server.

1 User visits the webpage: When a user visits the webpage with the embedded Tableau Server view, the webpage sends a GET request to your web server for the HTML for that page.

2 Web server POSTS to Tableau Server: The web server sends a POST request to the trusted Tableau Server (for example, `https://<server_name>/trusted`, not `https://<server_name>`). That POST request must have a `username` parameter. The `username` value must be the username for a licensed Tableau Server user. If Tableau Server is hosting multiple sites and the view is on a site other than the Default site, then the POST request must also include a `target_site` parameter.

3 Tableau Server creates a ticket: Tableau Server checks the IP address or host name of the web server (192.168.1.XXX in the above diagram) that sent the POST request. If the web server is listed as a trusted host then Tableau Server creates a ticket in the form of a unique string. Tickets must be redeemed within three minutes after they are issued. Tableau Server responds to the POST request with that ticket. Or if there is an error and the ticket cannot be created, then Tableau Server responds with a value of -1. The server must have an IPv4 address. IPv6 addresses are not supported. For more information, see Ticket Value of -1 Returned from Tableau Server.

4 Web server passes the URL to the browser: The web server constructs the URL for the view and inserts it into the HTML for the page. The ticket is included (for example, `https://<server_name>/trusted/<unique_ticket>/views/<view_name>`). The web server passes the HTML back to the client's web browser.

5 Browser requests view from Tableau Server: The client web browser sends a GET request to Tableau Server that includes the URL with the ticket.

6 Tableau Server redeems the ticket: Tableau Server redeems the ticket, creates a session, logs the user in, removes the ticket from the URL, and then sends the final URL for the embedded view to the client.

The session allows the user to access any of the views that the user would have if they logged onto the server. In the default configuration, users authenticated with trusted tickets have restricted access such that only views are available. They cannot access workbooks, project pages, or other content hosted on the server.

To change this behavior, see the `wgserver.unrestricted_ticket` option at tsm configuration set Options.

Tableau Server on Windows Help

How is a trusted ticket stored?

Tableau Server stores trusted tickets in the Tableau Server repository using the following process:

1. Tableau Server generates a two-part ticket: the first part is a Base64-encoded unique ID (UUID) and the second part is a 24-character random secret string.
2. Tableau Server hashes the secret string and stores it with the unique ID in the repository. Hashing takes the secret string as input, and uses an algorithm to compute a unique string. This unique string protects the security of the secret string from unauthorized users.
3. Tableau Server sends the Base64 UUID and the original 24-character random string to the client.
4. The client returns the Base64 UUID and the original 24-character secret string to Tableau Server as part of the request for a view.
5. Tableau Server locates the string pair with the Base64 UUID, and then hashes the secret string to verify that it matches the hash stored in the repository.

This process ensures that any trusted ticket content stored on Tableau Server cannot be used to impersonate users or access content protected by authentication. However, because the full trusted ticket is sent over HTTP between Tableau Server and the client, the process relies on secure and encrypted transmission of HTTP data. Therefore, we recommend that you only deploy trusted tickets over SSL/TLS or another layer of network encryption.

Add Trusted IP Addresses or Host Names to Tableau Server

The first step in setting up trusted authentication is to configure Tableau Server to recognize and trust requests from one or more web servers:

Use the TSM web interface

1. Open TSM in a browser:

`https://<server_name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click **User Identity & Access** on the **Configuration** tab and then click **Trusted Authentication**.
3. Under **Trusted Authentication**, for each trusted host, enter the name or IP address and then click **Add**:

Trusted Authentication
Use trusted authentication to allow single sign-on to view Tableau Server content embedded in webpages. Establish a trusted relationship between Tableau Server and one or more web server by adding trusted hosts and specifying token length for each trusted ticket. Do not set up trusted authentication if your web server uses SSPI. [Learn more](#)

Trusted hosts	<input type="text" value="10.32.139.6"/>	<input type="button" value="Delete"/>
	<input type="text" value="webserver1"/>	<input type="button" value="Delete"/>
	<input type="text" value="webserver2"/>	<input type="button" value="Add"/>
Token Length	<input type="text" value="24"/>	<input type="button" value="x"/>

Notes:

The values you specify completely overwrite any previous setting. Therefore, you must include the full list of hosts if you want to amend an existing list.

Static IP addresses are required: The web servers you specify must use static IP addresses, even if you use host names.

If you have one or more proxy servers between the computer that is requesting the trusted ticket (one of those configured in Step 2 as shown at Trusted Authentication) and Tableau Server, you also need to add them as trusted gateways using the `tsm configuration set gateway.trusted` option. See [Configuring Proxies and Load Balancers for Tableau Server](#) for steps.

4. Enter a value in **Token Length** (Optional).

Tableau Server on Windows Help

The token length determines the number of characters in each trusted ticket. The default setting of 24 characters provides 144 bits of randomness. The value can be set to any integer between 9 and 255, inclusive.

5. Click **Save Pending Changes** after you've entered your configuration information.
6. Click **Pending Changes** at the top of the page:

7. Click **Apply Changes and Restart**.

Use the TSM CLI

1. Enter the following command:

```
tsm authentication trusted configure -th <trusted IP address or  
host name>
```

In the command above, <trusted IP address> should be a comma-separated list of the IPv4 addresses or host names of your web server(s), with each host name or IP address in quotes.

Note: The values you specify completely overwrite any previous setting. Therefore, you must include the full list of hosts in the `tsm authentication trusted configure -th` command. (You cannot amend the list of hosts by running the `tsm authentication trusted configure -th` command repeatedly.)

For example:

```
tsm authentication trusted configure -th "192.168.1.101",  
"192.168.1.102", "192.168.1.103"
```

or

```
tsm authentication trusted configure -th "webserv1", "webserv2", "webserv3"
```

Notes:

Each host name or IP address in the list must be in double-quotes, followed by a comma and one space after each comma.

The web servers you specify must use static IP addresses, even if you use host names.

2. If you have one or more proxy servers between the computer that is requesting the trusted ticket (one of those configured in Step 2 as shown at Trusted Authentication) and Tableau Server, you also need to add them as trusted gateways using the `tsm configuration set gateway.trusted` option. See [Configuring Proxies and Load Balancers for Tableau Server](#) for steps.

3. Type the following command to save the changes to all the server configuration files:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

There are other optional trusted authentication configurations (legacy support, logging, and timeout settings) that you can make by passing a json file to Tableau Server. See `trustedAuthenticationSettings` Entity.

Next, you need to [configure your web server to receive tickets from Tableau Server](#).

Get a Ticket from Tableau Server

After you've [added trusted IP addresses](#) to Tableau Server, you're ready to configure your web server to get tickets from Tableau Server via POST requests ([Step 2 in the diagram](#)). The POST request must be sent to `http://<server_name>/trusted`. For example, the POST request must be sent to `http://tabserv/trusted` **not** `http://tabserv`.

Note: If SSL is enabled you must use https instead of http. For example: `https://tabserv/trusted`.

Here's the data you can use in a POST request to Tableau Server:

- **username=<username>** (required): The username for a licensed Tableau Server user. If you are using Local Authentication the username can be a simple string (for example, `username=jsmith`). If you are using Active Directory with multiple domains you must include the domain name with the user name (for example, `username=MyCo\jsmith`).
- **target_site=<site id>** (required if view not on Default site): Specifies the site containing the view if Tableau Server is running [multiple sites](#) and the view is on a site other than the Default site (for example, `target_site=Sales`). The value you use for `<site id>` should be the [Site ID](#) that was provided when the site was created. This value is case sensitive. If the **Site ID** is `SAles`, then the `target_site=SAles`.
- **client_ip=<IP address>** (optional): Used to specify the IP address of the computer whose web browser is accessing the view (for example, `client_ip=123.45.67.891`). It is not the IP address of the web server making the POST request of Tableau Server. If you decide to use this parameter, see [Optional: Configure Client IP Matching](#) for more information.

Tableau Server's response to the POST request will be a unique string (the ticket). If Tableau Server isn't able to process the request, the return will be `-1`. See [Ticket Value of -1 Returned from Tableau Server](#) for tips on how to correct this. Also, in order for users to successfully

authenticate when they click an embedded view, their browsers must be configured to **allow third-party cookies**.

The ticket format changed in Tableau Server 10.2. The ticket format is now a string composed of two parts. Each part is a 128 bit string that is encoded before it is returned to the client. The first part is a universally unique ID (UUID v4) that is Base64-encoded. The second part is a 24-character secure random string. The concatenation of these parts can be expressed as Base64(UUIDv4):SecureRandomString. An example of a ticket might look like this:

```
9D1ObyqDQmSIOyQpKdy4Sw==:dg62gCsSE0QRARXNTOp6mlJ5.
```

Next, you need to add code that allows the web server to **construct an URL** for the view that includes the view's location and the ticket.

Display the View with the Ticket

After you **create the POST request**, you need to write code that provides the web server with the view's location and the ticket from Tableau Server. It will use this information to display the view. How you specify it depends on whether the view is embedded, and if Tableau Server is running multiple sites.

Tableau Server View Examples

Here's an example of how to specify a view that users only access via Tableau Server (the view is not embedded):

```
http://<server_name>/trusted/<unique_ticket>/views/<workbook_name>/<view_name>
```

If Tableau Server is running **multiple sites** and the view is on a site other than the Default site, you need to add `t/<site_id>` to the path. For example:

```
http://<server_name>/trusted/<unique_ticket>/t/Sales/views/<workbook_name>/<view_name>
```

Use the same capitalization that you see in the Tableau Server URL.

Embedded View Examples

Here are some examples of how to specify embedded views. Because there are two approaches you can take with embed code, both ways are provided below. Regardless of which you use, there is some information unique to trusted authentication that you must provide. For more information, search for "Writing Embed Code" in the Tableau Server Help.

Note: The examples below use embed code parameters. For more information, see [Embed Code Parameters](#) in the Tableau Help.

Script Tag Examples

This example uses the `ticket` object parameter:

```
<script type="text/javascript" src-  
c="http://myserver/javascripts/api/viz_v1.js"></script>  
<object class="tableauViz" width="800" height="600" style-  
e="display:none;">  
    <param name="name" value="MyCoSales/SalesScoreCard" />  
    <param name="ticket" value-  
e="9D10byqDQmSIOyQpKdy4Sw==:dg62gCsSE0QRArXNTOp6m1J5" />  
</object>
```

Here's what the above example looks like for a multi-site Tableau Server, where the view is published on the `Sales` site:

```
<script type="text/javascript" src-  
c="http://myserver/javascripts/api/viz_v1.js"></script>  
<object class="tableauViz" width="800" height="600" style-  
e="display:none;">  
    <param name="site_root" value="/t/Sales" />  
    <param name="name" value="MyCoSales/SalesScoreCard" />  
    <param name="ticket" value-  
e="9D10byqDQmSIOyQpKdy4Sw==:dg62gCsSE0QRArXNTOp6m1J5" />  
</object>
```

Instead of using `ticket`, you can use the `path` parameter to state the full path of the view explicitly. When `path` is used, you do not also need the `name` parameter, which is usually a required parameter in Tableau JavaScript embed code:

```
<script type="text/javascript" src-
c="http://myserver/javascripts/api/viz_v1.js"></script>
<object class="tableauViz" width="900" height="700" style-
e="display:none;">
  <param name="path" value-
="tru-
sted/9D10byqDQmSIOyQpKdy4Sw-
w==:dg62gCsSE0QRARXNTOp6mlJ5/views/MyCoSales/SalesScoreCard" />
</object>
```

Here's the same example, but for a multi-site server. Note that `/t/<site_id>` is used here:

```
<script type="text/javascript" src-
c="http://myserver/javascripts/api/viz_v1.js"></script>
<object class="tableauViz" width="900" height="700" style-
e="display:none;">
  <param name="path" value-
="tru-
sted/9D10byqDQmSIOyQpKdy4Sw-
==:dg62gCsSE0QRARXNTOp-
p6mlJ5/t/Sales/views/MyCoSales/SalesScoreCard" />
</object>
```

Iframe Tag Example

```
<iframe src-
="h-
ttp://t-
abserver-
/trus-
ted/9D10byqDQmSIOyQpKdy4Sw-
w==:dg62gCsSE0QRARXNTOp6mlJ5/views/workbookQ4/SalesQ4?:embed=yes"
width="800" height="600"></iframe>
```

Optional: Configure Client IP Matching

By default, Tableau Server does not consider the client web browser IP address when it creates or redeems tickets. To change this, you need to do two things: specify an IP address using the `client_ip` parameter in the POST request that obtains the ticket, and follow the steps below to configure Tableau Server to enforce client IP address matching.

1. Open TSM CLI and type the following command:

```
tsm configuration set -k wgserver.extended_trusted_ip_checking  
-v true
```

2. Then type the following command:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Test Trusted Authentication

The steps below provide a method you can use to test retrieving a trusted ticket from your web server. This simple test can help evaluate connectivity between the web server and Tableau Server, and whether or not trusted authentication has been configured correctly.

Important: The test code provided in this topic runs client-side in the browser to provide a quick, visual validation that trusted authentication is configured correctly on Tableau Server. If the client browser loading the html page is not on the trusted web server, you may have to temporarily trust the client IP. In practice, you should never trust client IP addresses as part of your trusted authentication configuration. All trusted IP addresses are able to request tickets as any user including your administrator. In a production

environment, all trusted authentication flows should run server-side, between Tableau Server and the trusted web server(s) only.

Because the test is run on a client browser, the test isn't an exact replica of the communication path in a production environment. After successfully running the test, we recommend that you then test requesting tickets for your users with a server-side post request for final verification.

An alternative testing method is to run a trusted ticket generator to test your configuration. The following URL references a trusted ticket generator that is not supported by Tableau. However the generator has been used by many customers to test their trusted ticket configuration: <https://github.com/mkannan-tsi/Trusted-Ticket-Generator>.

Step 1: Add a test user

Create a user on the Tableau Server that you can use to test trusted ticket functionality. See [Add Users to Tableau Server](#). Add that user to a site on the server, and set the user's site role to **Explorer**.

Step 2: Create a test HTML page

Paste the following code into a new .html file that you save on the Tableau Server machine where you're performing the test from. You can change the labels and style attributes as you prefer.

```
<html>
<head>
<title>Trusted Ticket Requester</title>
<script type="text/javascript">
  function submitForm() {
    document.getElementById('form1').action =
    document.getElementById('server').value + "/trusted";
  }
```

Tableau Server on Windows Help

```
</script>
<style type="text/css">
    .style1 {width: 100%;}
    .style2 {width: 429px;}
    #server {width: 254px;}
</style>
</head>
<body>
<h3>Trusted Ticketer</h3>
<form method="POST" id="form1" onSubmit="submitForm()">
    <table class="style1">
        <tr>
            <td class="style2">Username</td>
            <td><input type="text" name="username" value="" /></td>
        </tr>
        <tr>
            <td class="style2">Server</td>
            <td><input type="text" id="server" name="server" value=
e="https://" /></td>
        </tr>
        <tr>
            <td class="style2">Client IP (optional)</td>
            <td><input type="text" id="client_ip" name="client_ip"
value="" /></td>
        </tr>
        <tr>
            <td class="style2">Site (leave blank for Default site; oth-
erwise enter the site name)</td>
            <td><input type="text" id="target_site" name="target_site"
value="" /></td>
        </tr>
```

```

<tr>
  <td class="style2"><input type="submit" name="submittable"
value="Get Ticket" /></td>
  <td>&#160;</td>
</tr>
</table>
</form>
<h4>Be sure to add your IP as a Trusted IP address to the server-
</h4>
</body>
</html>

```

Step 3: Retrieve a trusted ticket from Tableau Server

The following procedure will return a trusted ticket from Tableau Server.

1. Open the web page that you created in the previous step.

Trusted Ticketer

Username	<input type="text"/>
Server	<input type="text"/>
Client IP (optional)	<input type="text"/>
Site (leave blank for Default site; otherwise enter the site name)	<input type="text"/>
<input type="button" value="Get Ticket"/>	

Be sure to add your IP as a Trusted IP address to the server

This operation requires JavaScript, so the web browser might prompt you to allow scripts to run.

2. In the text boxes, enter the following:
 - **Username:** The test user that was created in Step 1.
 - **Server:** the address of your Tableau Server, e.g., `https://<server_name>`.
 - **Client IP (optional):** The IP address of the user's computer, if it's configured for

client trusted IP matching.

- **Site:** The name of the Tableau Server site that the test user is a member of.

3. Click **Get Ticket**. One of the following will be returned:

- **A unique ticket:** A trusted ticket is a string composed of a base64-encoded UUID and a 24-character random string, for example,
9D101xmDQmSIOyQpKdy4Sw==:dg62gCsSE0QRArXNTOp6mlJ5.
- **-1:** If the value, -1 is returned, the configuration contains an error. See Ticket Value of -1 Returned from Tableau Server.

Step 4: Test access with trusted ticket

Now that you have a ticket, you can use it to access content on Tableau Server.

Construct a URL with the unique ticket that you generated in the previous step to verify access with the trusted ticket. The URL syntax is different if you are accessing a Tableau Server with a single site vs a server that hosts multiple sites.

Default site server url

```
https://<server_name>/trusted/<unique_ticket>/views/<workbook_name>/<view_name>
```

Non-default site server url

```
https://<server_name>/trusted/<unique_ticket>/t/<site_name>/views/<workbook_name>/<view_name>
```

Variables in the URLs are indicated by angle brackets (< and >). All other syntax is literal.

Troubleshoot Trusted Authentication

This section includes some common issues and errors you might encounter when you're configuring trusted authentication.

A common source for trusted authentication errors are misconfiguration with a proxy server or load balancer. If your Tableau Server operates behind a reverse proxy server or a load bal-

ancer, see [Configure Tableau Server to work with a reverse proxy server and/or load balancer and Add a Load Balancer](#).

Trusted authentication information is written to `ProgramData\Tableau\Tableau Server\data\tabsvc\logs\vizqlserver\vizql-*.log`.

To increase the logging level from `info` to `debug`, run the following commands:

```
tsm configuration set -k vizqlserver.trustedticket.log_level -v
debug
tsm pending-changes apply
```

To test your trusted authentication deployment, see [Test Trusted Authentication](#).

See also

For more troubleshooting information for specific errors, see the following topics accessible from the **Other articles in this section** below:

Request for ticket by web server

- Ticket Value of -1 Returned from Tableau Server
- HTTP 401 - Not Authorized
- HTTP 404 - File Not Found
- Invalid User (SharePoint or C#)

Viewer redeeming ticket

- Attempting to Redeem the Ticket from the Wrong IP Address
- Cookie Restriction Error

Navigating between several embedded views

- An error occurred communicating with the server (403)

Ticket Value of -1 Returned from Tableau Server

Tableau Server returns -1 for the ticket value if it cannot issue the ticket as part of the trusted authentication process. Before troubleshooting this scenario, be sure to set the log level for trusted authentication to `debug` as specified in [Troubleshoot Trusted Authentication](#).

Tableau Server on Windows Help

The exact reason for this message is written to the `vizqlserver_node*-* .log.*` files in the following folder:

```
ProgramData\Tableau\Tableau Server\data\tabsvc\logs\vizqlserver
```

Here are some things to confirm:

- **All web server host names or IP addresses are added to trusted hosts**

The log error, "Invalid request host: <ip_address>" may indicate that the IP address or host name for the computer sending the POST request is not in the list of trusted hosts on Tableau Server. See [Add Trusted IP Addresses or Host Names to Tableau Server](#) to learn how to add IP addresses or host names to this list.

- **IP addresses are IPv4**

If you are using IP addresses to specify trusted hosts, they must be in Internet Protocol version 4 (IPv4) format. An IPv4 address looks like this: 123.456.7.890. IPv6 addresses (for example, fe12::3c4a:5eab:6789:01c%34) are not supported as a way of inputting trusted hosts.

- **Username in POST request is a valid Tableau Server user**

The username you send in the POST request must be a licensed Tableau Server user. You can see a list of users by signing in to Tableau Server as an administrator.

The following log errors indicate a user POST issue:

- "Missing username and/or client_ip"
- "Invalid user: <username>"
- "Unlicensed user is not allowed: <username>"

Username in POST request includes domain

If Tableau Server is configured to use Local Authentication, the username that you send in the POST can be a simple string. However, if the server is configured for Active Directory you must include the domain name with the user name (domain\username). For example, the username parameter might be: `username=dev\jsmith`. A common error log for this scenario is "Invalid user: <username>".

- **Content-Type is specified**

If you are designing an ASP.NET or C# application, you need to declare the content type in your HTTP request. For example:

```
http.setRequestHeader("Content-Type", "application/x-www-form-urlencoded; charset=UTF-8")
```

If you do not specify content type and Tableau Server returns a -1, the log files contain the error: "missing username and/or client_ip".

HTTP 401 - Not Authorized

If you receive a **401- Not Authorized error**, it could be for one of the following reasons:

- You may have configured Tableau Server to use Active Directory with SSPI. If your web server uses SSPI, you do not need to set up trusted authentication. You can embed views and your users will have access to them as long as they are licensed Tableau server users and members of your Active Directory. For more information, see `tsm authentication sspi <commands>`.

Note: SSPI can only be configured on Tableau Server for Windows.

- Or a **302- Redirect error** after you have deployed Tableau Server, then it's likely the trusted ticket code you have written to construct the URL for the client has not been updated to account for the two-part ticket URL format. For more information, see [Get a Ticket from Tableau Server](#).

HTTP 404 - File Not Found

You may receive this error if your program code references a Tableau Server URL that does not exist. For example, your web server may construct an invalid URL that cannot be found

when the webpage tries to retrieve it.

Another cause for this error is if you did not enter the trusted web servers as specified in Add Trusted IP Addresses or Host Names to Tableau Server. If you have already entered the trusted web servers, verify that the IP addresses or host names are correct.

Invalid User (SharePoint or C#)

You may encounter this error if you've configured Tableau Server for trusted authentication.

The example code for the SharePoint .dll references the following GET request:

```
SPContext.Current.Web.CurrentUser.Name
```

The above request will return the display name of the current Windows Active Directory user. If you want to use the login ID, then you will need to change the code to:

```
SPContext.Current.Web.CurrentUser.LoginName
```

After you make the change, recompile the SharePoint .dll.

Attempting to Redeem the Ticket from the Wrong IP Address

When you've configured Tableau Server for trusted authentication, you may encounter issues with redeeming the ticket.

This issue can occur when Tableau Server is configured to enforce client IP address matching. Because the client web browser IP address is not considered by default when redeeming the ticket, make sure that the client's web browser IP address that is sent in the POST request to Tableau Server is the same as when the browser tries to retrieve the embedded view.

For example, in the Trusted Authentication diagram, if the **POST request in step 3** sends the parameter `client_ip=74.125.19.147`, then the **GET request in step 5** must come from that same IP address.

For more information, see [Optional: Configure Client IP Matching](#) to learn how to configure Tableau Server to enforce client IP address matching.

Cookie Restriction Error

When a user signs in to Tableau Server, a session cookie is stored in their local browser. The stored cookie is how Tableau Server maintains that the signed in user has been authenticated and can access the server. Because the cookie is set with the same domain or sub-domain as the browser's address bar, it is considered a first-party cookie. If a user's browser is configured to block first-party cookies, they will be unable to sign in to Tableau Server.

When a user signs in to Tableau Server via an embedded view, or in an environment where trusted authentication has been configured, the same thing happens: a cookie is stored. In this case, however, the browser treats the cookie as a third-party cookie. This is because the cookie is set with a domain that's different from the one shown in the browser's address bar. If a user's web browser is set to block third-party cookies, authentication to Tableau Server will fail. To prevent this from occurring, web browsers must be configured to allow third-party cookies.

An error occurred communicating with the server (403)

If Tableau Server is configured for trusted authentication, you may receive this error after opening a new view in a browser and attempting to navigate back to views you'd opened earlier.

Tableau Server provides protection against unauthorized reuse of VizQL sessions through the tsm configuration set Options `vizqlserver.protect_sessions`, which is set to `true` by default. Because Tableau Server is configured for trusted authentication, you might not need this level of protection. To disable this option, you can use tsm configuration set Options to change `vizqlserver.protect_sessions` to `false`.

Personal Access Tokens

Personal access tokens (PATs) provide you and your Tableau Server users the ability to create long-lived authentication tokens. PATs enable you and your users to sign in to Tableau REST API without requiring hard-coded credentials (i.e., username and password) or interactive sign in. For more information about using PATs with Tableau REST API, see [Signing In and Out \(Authentication\)](#) in the Tableau REST API Help.

We recommend creating PATs for automated scripts and tasks that are created with the Tableau REST API:

- **Improve security:** Personal access tokens reduce risk in the event credentials are compromised. In the case where Tableau Server uses Active Directory or LDAP as an identity store, you can reduce the impact of credential compromise by using a personal access token for automated tasks. If a token gets compromised or is used in automation that is failing or posing a risk, you can just revoke the token. You do not need to rotate or revoke the user's credentials.
- **Audit and track:** As an administrator, you can review Tableau Server logs to track when a token is used, what sessions are created from that token, and the actions that are performed in those sessions. You can also determine if a session and the related tasks were performed from a session that was generated from a token or from an interactive signin.
- **Manage automation:** A token can be created for each script or task that is run. This allows you to silo and review automation tasks across your organization. Additionally, by using tokens then password resets or metadata changes (username, email, etc.) on user accounts will not disrupt automation as it would when credentials are hard-coded into the scripts.

Notes:

- To use PATs with tabcmd, install the compatible version of tabcmd from <https://tableau.github.io/tabcmd/>.
- PATs are not used for generic client access to the Tableau Server web UI or TSM.
- Configuring PATs expiration and disabling or limiting users access to PATs creation from the UI is available in Tableau Cloud only.

Understand personal access tokens

When a personal access token (PAT) is created, it is hashed then stored in the repository. After the PAT is hashed and stored, the PAT secret is shown once to the user and then no longer accessible after the users dismisses the dialog. Therefore, users are instructed to copy

the PAT to a safe place and to handle it as they would a password. When the PAT is used at run-time, Tableau Server compares the PAT presented by the user to the hashed value stored in the repository. If a match is made, then an authenticated session is started.

In the context of authorization, the Tableau Server session that is authenticated with a PAT has the same access and privileges as the PAT owner.

Note: Users can't request concurrent Tableau Server sessions with a PAT. Signing in again with the same PAT, whether at the same site or a different site, will terminate the previous session and result in an authentication error.

Server administrator impersonation

Beginning with version 2021.1, you can enable Tableau Server PAT impersonation. In this scenario, PATs that are created by server administrators can be used for **user impersonation** when using the Tableau REST API. Impersonation is useful in scenarios where you are embedding end-user-specific Tableau content within your application. Specifically, impersonation PATs allow you to build applications that query as a given user and retrieve content that the user is authorized for within Tableau Server, without hard-coding any credentials.

For more information, see [Impersonating a User](#) Tableau REST API Help.

Enable Tableau Server to accept personal access tokens during impersonation sign-in requests

By default, Tableau Server does not allow impersonation for server administrator PATs. You must enable the server-wide setting by running the following commands.

```
tsm authentication pat-impersonation enable [global options]
```

```
tsm pending-changes apply
```

Important: After you have run the commands, all PATs created by server administrators (including preexisting PATs) can be used for impersonation. To bulk-revoke all existing server administrator PATs, you can post the `DELETE /api/{api-ver-`

`sion}/auth/serverAdminAccessTokens` URI. For more information, see [Impersonating a User](#) in the Tableau REST API Help.

Create personal access tokens

Users must create their own PATs. Administrators cannot create PATs for users.

Users with accounts on Tableau Server can create, manage, and revoke personal access tokens (PATs) on the **My Account Settings** page. See [Manage Your Account Settings](#) in the Tableau User Help for more information.

Note: A user can have up to 10 PATs.

Change personal access tokens expiry

Personal access tokens (PATs) expire if they are not used after 15 consecutive days. If they are used more frequently than every 15 days, PATs expire after one year. After a year, new PATs must be created. Expired PATs will not display on the **My Account Settings** page.

You can change PATs expiration period by using the `refresh_token.absolute_expiry_in_seconds` option with the `tsm configuration set` command.

Revoke a personal access token

As an administrator, you can also revoke a user's PAT. A user can also revoke their own personal access tokens (PATs) on the **My Account Settings** page using the procedure described in the [Manage Your Account](#) topic in the Tableau User Help.

1. Sign in to Tableau Server as a server or site administrator.
2. Locate the user whose PAT you want to revoke. For more information about navigating Server Admin pages and locating users, see [View, Manage, or Remove Users](#).
3. Click the user's name to open their profile page.
4. On the user's profile page, click the **Settings** tab.

5. In the **Personal Access Tokens** section, identify the PAT that you want to revoke and then click **Revoke**.
6. In the dialog box, click **Delete**.

Track and monitor personal access token usage

All personal access token (PAT)-related actions are logged in the Tableau Server Application Server (vizportal) service. To locate PAT-related activities, filter log entries containing the string, `RefreshTokenService`.

A PAT is stored in this format: `Token Guid: <TokenID(Guid)>`, where the `TokenID` is a base64 encoded string. The secret value is not included in the logs.

For example:

```
Token Guid: 49P+CxmARY6A2GHxyvHHAA== (e3d3fe0b-1980-458e-80d8-61f1-caf1c700).
```

The following is an example snippet of two log entries. The first entry shows how a user is mapped to a PAT. The second entry shows a refresh event for the same PAT:

```
RefreshTokenService - Issued refresh token to the following user:
jsmith. Token Guid: 49P+CxmARY6A2GHxyvHHAA== (e3d3fe0b-1980-458e-80d8-61f1caf1c700)
RefreshTokenService - Redeemed refresh token. Token Guid:
49P+CxmARY6A2GHxyvHHAA== (e3d3fe0b-1980-458e-80d8-61f1caf1c700)
```

To locate key operations, filter log entries containing the string, `OAuthController`.

Configure Tableau Connected Apps to Enable SSO for Embedded Content

Beginning with Tableau Server version 2022.1, Tableau connected apps enable a seamless and secure authentication experience by facilitating an explicit trust relationship between your Tableau Server site and external applications where Tableau content is embedded. In Tableau Server 2022.3, Tableau connected apps extended its capabilities to support REST

API authorization. And as of Tableau Server 2023.3, REST API authorization via connected apps is respected by the Metadata API.

Connected apps offer the following benefits:

- Restrict access to which content can be embedded and where that content can be embedded
- Provide users the ability to access embedded content using single sign-on (SSO) without having to integrate with an identity provider (IdP)
- Provide users the ability to authenticate directly from your external application
- Programmatically authorize access to the Tableau REST API (and the Metadata API starting in Tableau Server 2023.3) on users' behalf using JSON Web Token (JWT)

Notes:

- Connected apps functionality, without UI, for Tableau Server became available in Tableau Server version 2021.4 through the [Connected App methods](#) in the Tableau REST API.
- To enable embedding through connected apps, Tableau Server must be configured to use SSL for HTTP traffic.
- In order for the session token to be valid, the clocks of the external application and the server that hosts the external application must be set to Coordinated Universal Time (UTC). If either clock uses a different standard, the connected app will not be trusted.
- Tableau connected apps and Salesforce connected apps are different and offer different functionality. Today, Tableau connected apps are optimized for embedding Tableau views and metrics in external applications. (In October 2023, Tableau retired the ability to embed metrics in Tableau Cloud and Tableau Server version 2023.3.)

How connected apps work

The trust relationship between your Tableau Server site and external application is established and verified through an authentication token in the JSON Web Token (JWT) standard, which uses a shared secret provided by the Tableau connected app and signed by your external application.

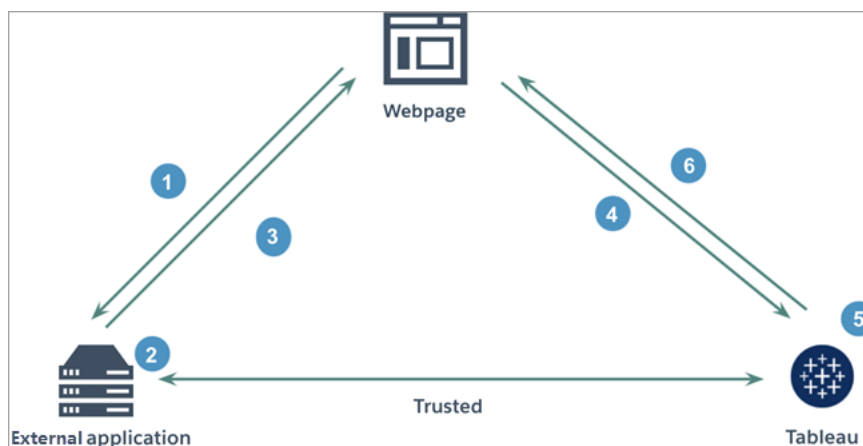

Key components of a connected app

The following components of the connected work together with the JWT in your external application to authenticate users and display embedded content.

- **Secrets:** Secrets are keys shared by Tableau and your external application. They are used in signatures that form the JWT. A secret is required when using connected apps for embedding authentication. Secrets can be created in a connected app, do not expire, and remain valid until deleted.
- **Domain allowlist:** You can specify a list of allowed domains in each connected app. Tableau content embedded through a connected app is only allowed under the specified domains. This helps ensure that content is exposed under the domains that are secured and approved by your business.
- **Access level:** You can specify what content can be embedded through a connected app by associating a connected app with one project or all projects. If you specify one project, only the content in the selected project can be embedded through the connected app.

Connected app workflow

The diagram below illustrates how authentication works between your external application (web server and webpage) and connected app.

1. **User visits the webpage:** When a user visits the embedded content on a webpage, webpage sends a GET request to your external application to retrieve the HTML on that webpage.

2. **external application constructs an authentication token:** The external application constructs a JWT, which contains a secret from the connected app (see Step 3 below for additional JWT requirements) and the scope of user access for the embedded content. The secret is signed by the external application and is used for verification of the trust relationship in a later step.
3. **external application responds with authentication token:** The external application responds to the page with the JWT in the embedded content's URL called by the webpage.
4. **Webpage requests content from Tableau:** With the attempt to load the embedded content, the webpage calls the embedded content's URL, which sends a GET request to Tableau.
5. **Tableau validates the token:** Tableau receives the JWT and verifies the trust relationship with the external application by identifying the connected app and shared secret used in the JWT. Then Tableau creates a session for the user. The session not only respects the embedding scopes defined in the JWT, but also the restrictions specified in the connected app, including the allowed domains and allowed projects.
6. **Tableau returns the content based on the restricted embedding context:** The embedded content only loads when the page is under an allowed domain and the content is published to an allowed project (if applicable). The authenticated user can only interact with the embedded content by the scope defined in the JWT.

Create a connected app

Step 1: Create a connected app

Create a connected app from Tableau Server's Settings page.

1. As a server admin, sign in Tableau Server.
2. From the left pane, select Settings > Connected Apps, and then click the **New Connected App** button.
3. In the Create Connected App dialog box, do one of the following:
 - a. For *REST API authorization workflows (including Metadata API workflows that use the REST API for authentication)*, in the Connected app name text box, enter a name for the connected app and click the **Create** button.

Note: You can ignore **Access level** and **Domain allowlist** when configuring a connected app for REST API and Metadata API authorization.

- b. For *embedding workflows*, do the following:
 - i. In the Connected app name text box, enter a name for the connected app.
 - ii. From the Applies to drop-down menu, select **All project** or **Only one project** to control which views or metrics can be embedded. If you select the "Only one project" option, select the specific project to scope to. For more information about these two options, see Access level (embedding workflows only).
 - iii. In the Domain allowlist, specify the domains using the rules described in Domain formatting below to control where views or metrics can be embedded.
 - iv. When finished, click the **Create** button.

Create Connected App

Connected app name: MyCo

Access level: Applies to: Only one project

Project name: MyCo

Domain allowlist:

☐ All domains

☒ Only specified domains:

 *.myco.com

Buttons: Cancel, Create

- Next to the connected app's name, click the actions menu and select **Enable**. For security purposes, a connected app is set to disabled by default when created.

- Make note of the connected app's ID, also known as the client ID, to use in Step 3 below.

Step 2: Generate a secret

You can generate a total of two secrets for each connected app. The second secret can be used for secret rotation purposes to help protect against issues if a secret is compromised.

- On the detail page of the connected app you created in Step 1, click the **Generate New Secret** button.
- Make note of the secret ID and secret value to use in Step 3 below.

Step 3: Configure the JWT

After you've generated a secret, you want to enable your external application to send a valid JWT. JWT is a standard used to securely transfer information between two parties. The JWT is

signed by your external application to securely send information to Tableau Server. The JWT references the connected app, the user that the session is being generated for, and the level of access the user should have.

A valid JWT includes the following information:

- Connected app ID, also known as the client ID, from Step 1
- Secret ID and secret value generated in Step 2
- Registered claims and header:

Claim	Name	Description or required value
"kid"	Secret ID	Required (in header). The connected app secret ID.
"iss"	Issuer	Required (in header). Unique issuer URI that identifies the trusted connect app and its signing key.
"alg"	Algorithm	Required (in header). JWT signing algorithm. Only HS256 is supported.
"sub"	Subject	User name of the authenticated Tableau Server user.
"aud"	Audience	Value must be: "tableau".
"exp"	Expiration Time	A valid JWT must not be expired. The expiration time of the JWT must be within the configured maximum validity period. The maximum validity period can be configured using the tsm viz-

		portal.oauth.connected_apps.max_expiration_period_in_minutes command.
"jti"	JWT ID	Required as a claim. The JWT ID claim provides a unique identifier for the JWT and is case sensitive.
"scp" Important: Do not use "scope".	Scope	<p>For <i>embedding workflows</i>, supported values include:</p> <p>"tableau:views:embed"</p> <p>"tableau:views:embed_authoring" (Added in Tableau Server 2022.3)</p> <p>"tableau:metrics:embed" (Retired in Tableau Server 2023.3)</p> <p>"tableau:ask_data:embed" (Added in Tableau Server version 2023.1)</p> <p>Notes:</p> <ul style="list-style-type: none"> • Values must be passed as a list type. • For tableau-views:embed, the scope respects users' permissions already configured in Tableau Server and allows users to interact with the tools in the embedded view if available in the original

		<p>view.</p> <ul style="list-style-type: none"> • We recommend the embed code exclude the toolbar parameter. For more information see Known issues (embedding workflows only) below. <p>For <i>REST API authorization workflows</i>, see REST API methods that support JWT authorization.</p> <p>For <i>Metadata API workflows that use the REST API for authentication</i>, the only supported scope is <code>tableau:content:read</code>.</p>
--	--	--

Example JWTs

Here are example JWTs in both Java and Python languages. The Java and Python examples use the nimbus-jose-jwt library and the PyJWT library, respectively.

Java

```
import com.nimbusds.jose.*;
import com.nimbusds.jose.crypto.*;
import com.nimbusds.jwt.*;

import java.util.*;

...

String secret = "secretvalue";
String kid = "connectedAppSecretId";
String clientId = "connectedAppClientId";
List<String> scopes = new
```

Tableau Server on Windows Help

```
ArrayList<>(Arrays.asList("tableau:views:embed"));
    String username = "username";
    JWSSigner signer = new MACSigner(secret);
    JWSHeader header = new
JWSHeader.Builder(JWSAlgorithm.HS256).keyID(kid).customParam("iss",
clientId).build();
    JWTClaimsSet claimsSet = new JWTClaimsSet.Builder()
        .issuer(clientId)
        .expirationTime(new Date(new Date().getTime() + 60 * 1000)) //ex-
pires in 1 minute
        .jwtID(UUID.randomUUID().toString())
        .audience("tableau")
        .subject(username)
        .claim("scp", scopes)
        .build();
    SignedJWT signedJWT = new SignedJWT(header, claimsSet);
    signedJWT.sign(signer);
    model.addAttribute("token", signedJWT.serialize());
```

Python

```
import jwt
token = jwt.encode(
    {
        "iss": connectedAppClientId,
        "exp": datetime.datetime.utcnow() + datetime.timedelta(minutes=5),
        "jti": str(uuid.uuid4()),
        "aud": "tableau",
        "sub": user,
        "scp": ["tableau:views:embed", "tableau:metrics:embed"]
    },
    connectedAppSecretKey,
    algorithm = "HS256",
    headers = {
        'kid': connectedAppSecretId,
        'iss': connectedAppClientId
```

```
}
)
```

After you've configured the JWT, when the code is run by your external application, it will generate a token.

Step 4: Next steps

For embedding workflows

After JWT has been configured, you must add embed code to your external application. Ensure that you include the valid JWT you configured in Step 3 above in the web component that your external application calls.

For more information about embedding Tableau content, see one or both of the following:

- Embed metrics, see [Embed Metrics into Webpages](#) topic in the Tableau Help. (In Tableau Server 2023.3, Tableau retired the ability to embed metrics.)
- Embed Tableau views and metrics using the [Tableau Embedding API v3](#).

Note: For users to successfully authenticate when they access embedded content, browsers must be configured to allow third-party cookies.

For REST API authorization workflows

After the JWT has been configured, you must add the valid JWT to the REST API Sign In request for authorized access. For more information, see [Access Scopes for Connected Apps](#).

For Metadata API workflows

After the JWT has been configured, you must add the valid JWT to the REST API Sign In request. For more information, see [Access Scopes for Connected Apps](#).

Manage a connected app

The Connected Apps page is where you can manage all the connected apps for your site. You can perform tasks such creating, deleting, and disabling connected apps; and revoking

or generating new secrets if existing secrets have been compromised.

1. As a server or site admin, sign in to Tableau Server.
2. From the left pane, select **Settings > Connected Apps**.
3. Select the check box next to the connected app you want to manage and do one or more of the following:
 - **Generate a new secret** according to the rotation time line specified by your organization's security policies. To generate an additional secret, click on the name of the connected app and then click the **Generate New Secret** button. A connected app can have a maximum of two secrets. Both secrets can be active at the same time, do not expire, and remain valid until deleted.
 - **Review the connected app details** by clicking the name of the connected app to see when the connected app was created, its ID, project and domain scopes, and its secrets.
 - **Change the project scope or domain**, in the Actions menu, select **Edit**. Make your changes and click **Update**.

Note: If you change the project or domain scopes and the embedded content doesn't exist in either the new project or new domain, the embedded view or metric is unable to display and users will see an error when accessing the embedded content.

- **Delete a secret** by clicking the connected app's name. On the connected app's page, click **Actions** next to the secret and select **Delete**. In the confirmation dialog box, select **Delete** again.

Note: If the connected app's secret is being used by an external application, the embedded view or metric is unable to display after the secret is deleted. For more

information, see Effects of disabling or deleting a connected app, or deleting a secret below.

- **Disable a connected app**, in the Actions menu, select **Disable**. If the connected app is being used by the external application, the embedded view or metric is unable to display after the connected app is disabled. For more information, see Effects of disabling or deleting a connected app, or deleting a secret below.

Effects of disabling or deleting a connected app, or deleting a secret

To display an embedded view or metric to your user through a connected app requires the connected app to be enabled and secret generated. If the connect app is being used in your

external application and is either disabled or deleted, or its secret deleted or replaced, users will get an error when accessing the embedded content.

To avoid this issue, ensure the connect app is enabled and the JWT is using the correct secret ID and value.

Access level (embedding workflows only)

You can select one of two project types when configuring a connected app's access level. The access level controls which content can be embedded.

- **All projects:** This option enables the content in all projects to be embedded.
- **Only one project:** This option enables only the content in the specified project to be embedded. If the specified project contains nested projects, embedding content in those nested projects is not enabled.

Domain allowlist rules (embedding workflows only)

The connected app's domain allowlist enables you to restrict access to embedded Tableau content to all domains or some domains; or exclude some domains or block all domains.

Domain options

You can select one of two options when configuring a connected app's domain allowlist:

- **All domains:** As the default option, this option enables unrestricted access to embedded content.
- **Only specific domains:** This option gives you the ability to scope down access to embedded content. If you use this option, follow the formatting rules specified in the following section, Domain formatting.

Domain formatting

In the domain allowlist text box, you can enter one or more domains using the formatting examples below.

Note: Domain formatting rules also apply when using the [Connected App methods](#) in the Tableau REST API.

Here are some formatting examples based on common scenarios:

To specify...	Example	Embedding access
Range of domains	*.myco.com	Embedded content is accessible from all subdomains under myco.com.
All ports	myco.com:*	Embedded content is access from all ports in myco.com.
Specific port	myco.com:8080	Embedded content is accessible from port 8080 in myco.com only.
Multiple discrete domains	myco.com events.myco.com ops.myco.com	Embedded content is accessible from all three domains. Note: When specifying multiple domains, type each domain on a new line or separate domains with a space. For the REST API, domains must be separated by a space.
Secure traffic only	https:	Embedded content is securely accessible regardless of domain.
Secure traffic to all ports for a range of domains	https:*myco.com:*	Embedded content is securely accessible from all ports on all subdomains under myco.com.
No domains	[no domains]	Access to embedded content is blocked.

Known issues (embedding workflows only)

There are a couple of known issues when using connected apps that will be addressed in a future release.

- **Toolbar features:** When embedded content has the toolbar parameter defined, not all toolbar features will work. To work around this issue, we recommend you hide the toolbar parameter like in the example below.

```
<tableau-viz id='tab-viz' src='https://<your_server>/t/<your_
site>/...'
      toolbar='hidden'>
</tableau-viz>
```

- **Published data sources:** Published data sources set to **Prompt User** for database credentials will not display. To work around this issue, if possible, we recommend data source owners embed their database credentials instead.
- **Ask Data objects in embedded dashboards:** Ask Data objects in embedded dashboards will not load.
- **Metrics and domain allowlists:** Embedded metrics views will display despite access restrictions that might be specified in the connected apps' domain allowlists. **Note:** Metrics data accessed from toolbars of embedded views will work as expected. (In Tableau Server 2023.3, Tableau retired the ability to embed metrics.)

Access Scopes for Connected Apps

Starting with Tableau Server version 2022.3, using Tableau connected apps, you can programmatically call and access the Tableau REST API through your custom application on behalf of Tableau Server users. Access to the REST API is enabled by a JSON Web Token (JWT) defined as part of the initial Sign In request. The JWT must contain scopes that define the REST API methods that are available to your custom application and its users through the connected app.

Authorize access to the REST API using connected apps to:

- Enhance security—using a JWT as a bearer token is inherently more secure than storing and managing admin user passwords through .env files in vaults
- Enhance efficiency—using a JWT as a bearer token enables a simplified impersonation with one request to the Sign In endpoint instead of two requests

- Extend and automate complex Tableau integrations and backend queries—such as dynamic content retrieval and advanced filtering

Scope actions

Connected apps use scopes that grant access to content or administrative actions through the REST API methods that support JWT authorization (below). A scope is a colon-separated string that starts with the namespace `tableau`, followed by the Tableau resource that access is being granted to, such as `datasources`, and ends with the action that is allowed on the resource, such as `update`.

The action a scope can take include:

- `create`
- `read`
- `run`
- `update`
- `download`
- `delete`

For example, a scope that allows your custom application to call the [Update Data Source](#) method looks like:

```
tableau:datasources:update
```

Scope types

The type of scope you use depends on the content or administrative action that you want to enable. Scopes generally fall into one of the following types: content read, individual, wild-card, and cross-category.

- **Content read scope:** The content read scope, `tableau:content:read`, enables supported GET methods for Tableau content. When you use this scope, you enable actions across REST API categories. More specifically, using this scope you enable GET methods for data sources, metrics, views, workbooks, projects, and sites. Starting in Tableau Server 2023.3, you also specify this scope in a JWT that will be used to create a credentials token for use with the [Metadata API](#).

Note: To enable GET methods for administrative actions, like users and groups, you can use their individual scopes.

- **Individual scopes:** To enable supported content and administrative actions, you can use their individual scopes. An individual scope is generally associated with a single method and REST API category.

Examples:

- To enable publish or update a data source action, you can use the individual `tableau:datasources:create` or `tableau:datasources:update` scope, respectively.
- For administrative actions like add or remove users, you can use the individual `tableau:users:create` or `tableau:users:delete` scope, respectively.

Note: There are some individual scopes that can enable actions across REST API categories. For example, `tableau:views:download` enables actions in the view data and workbooks REST API categories.

- **Wildcard (*) scopes:** For certain scopes, you can replace the action with the wildcard character (*) to enable supported actions within a specific REST API category.

Examples:

- You can use the `tableau:projects:*` wildcard scope to enable the create, delete, update actions in the projects REST API category.
- You can use the `tableau:users:*` wildcard scope to enable the get/list, add, delete, update actions in the users REST API category.
- You can use the `tableau:tasks:*` wildcard scope to enable the get/list, add, delete, update and run actions of extract and subscriptions REST API categories. In addition, this scope enables update data source (if an extract) and update workbook.
- **Cross-category scopes:** In addition to the content read scope, there are a few additional scopes that, if used, enable supported actions across different REST API categories.

Examples:

- If using the `tableau:tasks:run` scope, you enable actions in the data sources and workbooks REST API categories.
- Again, if using the `tableau:views:download` scope, you enable actions in the view data and workbook REST API categories.
- If using permissions scopes like `tableau:permissions:update` or `tableau:permissions:delete`, you enable actions in the data sources, workbooks, and projects REST API categories.

Summary of how to authorize REST API access

The following list summarizes the steps to request access to the REST API through a JWT:

1. **Create a connected app** using one of the following methods:
 - Configure Tableau Connected Apps to Enable SSO for Embedded Content
 - Register EAS to Enable SSO for Embedded Content
2. **Generate a valid JWT**—at runtime your custom application will generate a valid JWT, configured with the scopes you have included
3. **Make a Sign In request**—your custom application will make a Sign In request using the JWT to return a Tableau credentials token and site ID (LUID)
4. **Use the Tableau access token in subsequent requests**—in subsequent REST API calls, use 1) the Tableau credentials token as the `X-Tableau-Auth` header value and 2) the site ID (LUID) in the request URI

Example

For example, suppose you create a connected app using direct trust. Using direct trust, your custom application that calls the REST API generates a valid JWT using the client ID and client secret generated by the connected app.

Scopes in the JWT

To successfully authorize access to the REST API, the JWT must also contain the scopes that define the REST API capabilities. For example, to enable various data source-related methods, you might include the following scopes in the JWT:

```
"tableau-
```

Tableau Server on Windows Help

```
:con-  
tent:read", "t-  
ableau-  
:data-  
sources:cre-  
ate", "t-  
ableau-  
:data-  
sources:update", "tableau:datasources:download", "tableau:tasks:run"
```

Or

```
"tableau:content:read", "tableau:datasources:*", "tableau:tasks:run"
```

Note: Scope values must be passed as a list type.

Sign In Request URI

To make a call to the REST API, your custom application must first make a Sign In request to generate a Tableau credentials token.

```
POST https://myco/api/3.17/auth/signin
```

Request body

To authorize REST API access using a JWT, the Sign In request body must contain the valid JWT like the example below.

```
<tsRequest>  
  <credentials jwt-  
="eyJ-  
pc3MiOiI4ZTFiNzE3Mi0zOWMzLTRhMzItODg3ZS1mYzJiNDExOWY1NmQiLCJh-  
bGciOiJIUzI1NiIsImt-  
pZCI6ImIwMTE1YmY5LTNhNGItNGM5MS1iMDA5LWNmMGxNzBiMWE1NiJ9.eyJh-  
dWQiOiJ0YWJsZWFlIi-  
wic3ViI-
```

```

joicmlvaGFuQHRhYmxlYXUuY29tIi-
wic2NwIjp-
bInRhYmxlYXU6c2l0ZXM6cmVhZCJdLCJp-
c3MiOiI4ZTFiNzE3Mi0zOWMzLTRhMzItODg3ZS1mYzJiNDExOWY1NmQiLCJleHAiOjE-
2NDg2Njg0Mzk-
sIm-
p0aSI6IjYlZWVmMmYxLTNmZTgtNDc5Ny1hZmRiLTMyODMzZDVmZGJkYSJ9.mUv2o4gt-
BTrMVLEXY5XTpzDQTGvfE2LGi-3O2vdGfT8">
    <site contentUrl="mycodotcom"/>
  </credentials>
</tsRequest>

```

Response body

The Sign In request produces the following response body, which includes the Tableau credentials token.

```

<tsResponse>
  <credentials token="12ab34cd56ef78ab90cd12ef34ab56cd">
    <site id="9a8b7c6d5-e4f3-a2b1-c0d9-e8f7a6b5c4d" contentUrl=""/>
    <user id="9f9e9d9c-8b8a-8f8e-7d7c-7b7a6f6d6e6d" />
  </credentials>
</tsResponse>

```

After the Tableau access token is generated, add the Tableau credentials token to the header of all subsequent REST API requests.

Header

```
X-Tableau-Auth:12ab34cd56ef78ab90cd12ef34ab56cd
```

All subsequent REST API requests using the Tableau access token are then bounded by the scopes in the JWT.

REST API methods that support JWT authorization

The following scopes can be associated with the connected app to define access and methods your custom application can have to the **REST API** on users' behalf.

Notes:

- For other REST API capabilities not listed in the table below, you can use other authorization mechanisms to access the methods. For more information, see [Authentication Methods](#) in the Tableau REST API Help.
- For scopes supported by the Embedding API v3, see one of the following:
 - [Configure Tableau Connected Apps to Enable SSO for Embedded Content](#)
 - [Register EAS to Enable SSO for Embedded Content](#)

Wildcard (*) scopes

Wildcard scopes use the wildcard character (*) instead of a specific action, to enable multiple supported actions within a specific REST API category. These include:

Scope	Methods enabled
<code>tableau:datasources:*</code>	Enables create, update, and update connection data source methods.
<code>tableau:metrics:*</code>	Enables query, update, and delete metrics actions.
<code>tableau:workbooks:*</code>	Enables publish, update, download, and preview image workbook actions.
<code>tableau:groups:*</code>	Enables create, query, update, and delete groups actions.
<code>tableau:projects:*</code>	Enables create, delete, and update projects methods.
<code>tableau:users:*</code>	Enables get/list, add, delete, and update users methods.
<code>tableau:tasks:*</code> Note: This scope is also cross-category.	Enables get/list, add, delete, update and run methods for extracts and subscription tasks. Enables update methods for data sources for workbooks.

Cross-category scopes

Cross-category scopes enable multiple supported actions across multiple REST API categories. These include:

Scope	Methods enabled
<code>tableau:content:read</code>	Enables read/list methods for Tableau content, including data sources, metrics, views, workbooks, projects, and sites.
<code>tableau:tasks:run</code>	Enables run methods for data sources, workbooks, and extracts.
<code>tableau:views:download</code>	Enables download methods for view data and workbooks.
<code>tableau:tasks:*</code> Note: This scope is also wild-card.	Enables get/list, add, delete, update and run methods for extracts and subscription tasks. Enables update methods for data sources for workbooks.

Individual scopes

Method	Scope	Description
(Methods without scopes)	(None)	When no scopes are defined in the JWT, access to the REST API is denied.
Sign in	(No scope needed)	Signs you in as a user on the specified site on

Method	Scope	Description
		Tableau Server.
Sign out	(No scope needed)	Signs you out of the current session.
(Content read scope)	<code>tableau:content:read</code>	Enables read/list actions for Tableau content: data sources, metrics, views, workbooks, and projects.
Data sources		
(All <code>tableau:datasources: methods</code>)	<code>tableau:datasources:*</code>	Enables create data source, update data source, and update data source connection methods.
Publish data source	<code>tableau:datasources:create</code>	Publish a data source to a site or append data to an existing published data source.

Method	Scope	Description
Query data source	<code>tableau:content:read</code>	Get information about a published data source.
Query data sources	<code>tableau:content:read</code>	Get information about all published data source on a site.
Query data source connections	<code>tableau:content:read</code>	Get server address, port, user name, or password information about a published data source.
Update data source	<code>tableau:datasources:update</code>	Update owner, project or certification status of the data source.
Update data source connection	<code>tableau:datasources:update</code>	Update server address, port, user name, or password of the data source connection.
Update data source now	<code>tableau:tasks:run</code>	Run extract refresh.

Method	Scope	Description
Extracts		
(All <code>tableau:tasks:</code> methods)	<code>tableau:tasks:*</code>	Enables create, delete, get, list, run, and update refresh actions for extracts, subscriptions, update data source (for data sources with extracts), and update workbook methods.
List extract refresh tasks in site	<code>tableau:tasks:read</code>	List the extract refreshes tasks configured for in a site.
Run extract refresh task	<code>tableau:tasks:run</code>	Runs an extract refresh task.
Flows		
Publish flow	<code>tableau:flows:create</code>	Publish a flow.
Metrics		

Method	Scope	Description
Important changes coming for Ask Data and Metrics <p>Tableau's Ask Data and Metrics features will be retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see How Tableau GPT and Tableau Pulse are reimagining the data experience.</p> <p>In October 2023, Tableau retired the ability to embed metrics in Tableau Cloud and Tableau Server version 2023.3, in advance of the retirement of the Metrics feature</p>		
(All <code>tableau:metrics:</code> methods)	<code>tableau:metrics:*</code>	Enables query, update, and delete metrics actions.
(All <code>tableau:metrics:</code> methods)	<code>tableau:metrics:*</code>	Enables query, update, and delete metrics actions.
Get metric	<code>tableau:content:read</code>	Get a metric.
Delete metric	<code>tableau:metrics:delete</code>	Delete a metric.
List metrics	<code>tableau:content:read</code>	Get list of metrics for a site.
Query metrics data	<code>tableau:metrics:download</code>	Get underlying data of a metric in

Method	Scope	Description
		comma-separated value (.csv) format.
Update metric	<code>tableau:metrics:update</code>	Update owner, project, suspend status, and name of the metric.
Subscriptions		
(All <code>tableau:tasks:</code> methods)	<code>tableau:tasks:*</code>	Enables create, delete, get, list, run, and update refresh actions for extracts, subscriptions, update data source (for data sources with extracts), and update workbook methods.
Create subscription	<code>tableau:tasks:create</code>	Create a subscription.
Delete subscription	<code>tableau:tasks:delete</code>	Delete a subscription.
Get subscription	<code>tableau:tasks:read</code>	Gets the

Method	Scope	Description
		details of a subscription.
List subscriptions	tableau:tasks:read	Lists sub- scriptions in a site.
Update subscription	tableau:tasks:update	Updates a subscription.
Views		
Delete custom view	tableau:views:update	Delete the specified cus- tom view.
Get custom view	tableau:content:read	Get the details of a specified cus- tom view.
Get custom view image	tableau:views:download	Download a .png format image file of a specified cus- tom view.
Get view	tableau:content:read	Get details about a view.
Get view by path	tableau:content:read	Get details for all views on a site using the specified name.
List custom views	tableau:content:read	Get a list of

Method	Scope	Description
		custom views on a site.
Query view data	<code>tableau:views:download</code>	Get a view rendered in comma-separated value (.csv) format.
Query view PDF	<code>tableau:views:download</code>	Get a view as a PDF (.pdf) file.
Query view image	<code>tableau:views:download</code>	Get a view as an image (.png) file.
Query views for site	<code>tableau:content:read</code>	Get all views for a site.
Query views for workbook	<code>tableau:content:read</code>	Get all views for the specified workbook.
Query view preview image	<code>tableau:views:download</code>	Get the thumbnail image (.png) of the view.
Update custom view	<code>tableau:views:update</code>	Change the owner or name of an existing custom view.

Method	Scope	Description
Workbooks		
(All tableau- :workbooks: methods methods)	tableau:workbooks:*	Enables publish, update, download, and preview image workbook actions.
Publish workbook	tableau:workbooks:create	Publish a workbook (.twb or .twbx).
Query workbook	tableau:content:read	Get a specified workbook and its details.
Query workbook for site	tableau:content:read	Get a list of workbooks published to a site.
Query workbook preview image	tableau:workbooks:download	Get the thumbnail image (.png) of the workbook.
Update workbook	tableau:workbooks:update	Modify an existing workbook.
Update workbook connection	tableau:workbooks:update	Update the connection information.

Method	Scope	Description
Update workbook now	<code>tableau:tasks:run</code>	Initiate a workbook refresh outside of a scheduled task.
Publish		
Append to file upload	<code>tableau:file_uploads:create</code>	Upload a block of data and append it to the data that is already uploaded - to be used after an upload has been initiated using the "initiate file upload" method.
Initiate file upload	<code>tableau:file_uploads:create</code>	Initiate the upload process of a file.
Download		
Download data source	<code>tableau:datasources:download</code>	Download the data source (.tdsx).
Download view crosstab Excel	<code>tableau:views:download</code>	Download an Excel (.xlsx) file containing

Method	Scope	Description
		crosstab data from the view.
Download workbook	<code>tableau:workbooks:download</code>	Download a workbook (.twb or .twbx).
Download workbook revision	<code>tableau:workbooks:download</code>	Download a specific version of the workbook (.twb or .twbx).
Download workbook PDF	<code>tableau:views:download</code>	Download a PDF (.pdf) file containing images of the sheets in the workbook.
Download workbook PowerPoint	<code>tableau:views:download</code>	Download a PowerPoint (.pptx) file containing slides of the sheets in the workbook.
Users		
(All <code>tableau:users</code> methods)	<code>tableau:users:*</code>	Enables add, query, update, and remove users

Method	Scope	Description
		actions.
Add user to group	<code>tableau:groups:update</code>	Add a user to a group.
Add user to site	<code>tableau:users:create</code>	Add a user and assign the user to a site.
Get users in group	<code>tableau:groups:read</code>	Get a list of users in a group.
Get users on site	<code>tableau:users:read</code>	Get all users on a site.
Query user on site	<code>tableau:users:read</code>	Get a user on a site.
Remove users from group	<code>tableau:groups:update</code>	Remove a user from a group.
Remove user from site	<code>tableau:users:delete</code>	Remove the user from a site.
Groups		
(All <code>tableau:groups:</code> methods)	<code>tableau:groups:*</code>	Enables create, query, update, and delete groups actions.
Create group	<code>tableau:groups:create</code>	Create a group.

Method	Scope	Description
Delete group	<code>tableau:groups:delete</code>	Delete a group.
Get groups for user	<code>tableau:users:read</code>	Get a list of groups that a user belongs to.
Query groups	<code>tableau:groups:read</code>	Get a list of groups on a site.
Update group	<code>tableau:groups:update</code>	Update a group.
Projects		
(All <code>tableau-projects: methods</code>)	<code>tableau:projects:*</code>	Enables create, update, and delete projects actions.
Create project	<code>tableau:projects:create</code>	Create a project.
Delete project	<code>tableau:projects:delete</code>	Delete a project.
Query project	<code>tableau:content:read</code>	Get a list of projects.
Update project	<code>tableau:projects:update</code>	Update the name, description, or project hierarchy of the project.

Method	Scope	Description
Permissions		
(All <code>tableau- :permissions: meth- ods</code>)	<code>tableau:permissions:*</code>	Enables add, query, update, delete permissions actions.
Add data source permissions	<code>tableau:permissions:update</code>	Add permissions to a data source for a Tableau Server user or group.
Add default permissions	<code>tableau:permissions:update</code>	Add default permission capabilities to a user or group, for metric, flow, workbook, data source, data role, or lens resources in a project.
Add project permissions	<code>tableau:permissions:update</code>	Add permissions to a project for a user or group
Add view permissions	<code>tableau:permissions:update</code>	Add permissions to a view for a user or group.

Method	Scope	Description
Add workbook permissions	<code>tableau:permissions:update</code>	Add permissions to a specified workbook for a user or group.
Delete data source permissions	<code>tableau:permissions:delete</code>	Delete default permission capabilities of a user or group, for metric, flow, workbook, data source, data role, or lens resources in a project.
Delete default permissions	<code>tableau:permissions:delete</code>	Delete default permission capabilities of a user or group, for metric, flow, workbook, data source, data role, or lens resources in a project.
Delete project permissions	<code>tableau:permissions:delete</code>	Delete the project permission for a user or group.

Method	Scope	Description
Delete view permissions	<code>tableau:permissions:delete</code>	Delete the view permission for a user or group.
Delete workbook permissions	<code>tableau:permissions:delete</code>	Delete the workbook permission for a user or group.
Query data source permissions	<code>tableau:permissions:read</code>	Get a list of permissions for the data source.
Query default permissions	<code>tableau:permissions:read</code>	Get default permission capabilities of users and groups for metrics, workbooks, and data sources.
Query project permissions	<code>tableau:permissions:read</code>	Get a list of permissions for the project.
Query view permissions	<code>tableau:permissions:read</code>	Get a list of permissions for the view.
Query workbook permissions	<code>tableau:permissions:read</code>	Get a list of permissions for the workbook.

Method	Scope	Description
Site		
(All <code>tableau:sites:</code> methods)	<code>tableau:sites:*</code>	Enables create, query, update, and delete sites actions.
Create site	<code>tableau:sites:create</code>	Create a site on Tableau Server.
Delete site	<code>tableau:sites:delete</code>	Delete a site on Tableau Server.
Get recently viewed site	<code>tableau:content:read</code>	Get views and workbooks details on the most recently created, updated, or accessed by the signed in user.
Query sites	<code>tableau:sites:read</code>	List all sites on Tableau Server.
Query views for site	<code>tableau:content:read</code>	List all views on a site.
Update site	<code>tableau:sites:update</code>	Update a site.

401001 - signin error

If you encounter error 401001, the **Sign In** response body is appended with one of the following additional connected apps-specific error codes: 16, 10084, or 10085.

For example, in the following response body, "10084" is the connected apps error code you can use to help troubleshoot issues with signing in to Tableau Server using a JWT for REST API authorization.

```
<error code="401001">
  "summary": "Signin Error",
  "detail": "Error signing in to Tableau Cloud (10084)"
</error>
```

To help resolve the issue, refer to the description of the applicable error code and its potential causes.

- **16: Could not find user**—this error can occur because the incorrect "sub" (user name) was specified
- **10084: Could not parse access token**—this error can occur for the following reasons:
 - JWT is invalid or there was an unexpected problem
 - Incorrect "aud" (audience) was specified
 - For direct trust, there was a problem with signing the secret
- **10085: Could not fetch secret to verify signature for client ID**—this error can occur for the following reasons:
 - Incorrect client ID in "iss" specified
 - For direct trust, incorrect "kid" (secret ID) was specified
 - For EAS, unable to fetch keys from the JWKSSource

401002 - unauthorized access error

If you encounter error 401002 and have confirmed that you have the appropriate permissions to make the request, ensure the scope included in the JWT is correct and matches the request you're trying to make. For a list of endpoints and supported scopes, see the REST API methods that support JWT authorization section above.

Troubleshoot Connected Apps

When embedded content fails to display in your custom application or Tableau REST API authorization fails, you can use a browser's developer tools to inspect and identify error codes that might be associated with the Tableau connected app (direct trust) that's used to display the embedded content.

Refer to the table below to review the description of the error code and potential resolution.

Error code	Summary	Description	Potential resolution or explanation
5	SYSTEM_USER_NOT_FOUND	Tableau user could not be found	To resolve this issue, verify the 'sub' (Subject) claim value in the JWT is "username" for Tableau Server. This value is case sensitive.
16	LOGIN_FAILED	Login failed	<p>This error is typically caused by one of the following claim issues in the JWT:</p> <ul style="list-style-type: none"> The 'exp' (Expiration Time) exceeds the default maximum validity period. To resolve this issue, review registered claims required for a valid JWT and ensure the correct value is used. To change the maximum

			<p>validity period, you can use the viz-portal.oauth.connected_apps.max_expiration_period_in_minutes command.</p> <ul style="list-style-type: none"> The 'sub' (Subject) is calling an unknown user. To resolve this issue, verify the 'sub' claim is "username". This value is case sensitive.
67	FEATURE_NOT_ENABLED	On-demand access is not supported	On-demand access is available through licensed Tableau Cloud sites only.
126	CONNECTED_APP_NOT_FOUND	The connected app could not be found	To resolve this issue, verify the connected app is enabled and the correct client ID (also known as the connect app ID) is referenced in the JWT.
127	CONNECTED_APP_SECRET_NOT_FOUND	The connected app's secret could not be found	To resolve this issue, verify the correct connected app's secret ID and secret value are referenced in the JWT.
128	CONNECTED_APP_SECRET_LIMIT_EXCEEDED	Maximum limit for secrets has been reached	<p>A maximum of two secrets are allowed for a connected app. This error can occur when there's an attempt to create a third secret.</p> <p>To resolve this issue, delete a secret from the connected app before creating a new one.</p>
133	INVALID_	Domain allowl-	This error can occur when the

	CONNECTED_APP_DOMAIN_SAFELIST	ist contains one or more invalid characters	domain allowlist contains one or more invalid characters.
10083	BAD_JWT	JWT header contains issues	The 'kid' (Secret ID) or 'clientId' (Issuer) claims are missing from the JWT header. To resolve this issue, ensure this information is included.
10084	JWT_PARSE_ERROR	JWT contains issues	To resolve this issue, verify the following: <ul style="list-style-type: none"> • The 'aud' (Audience) value referenced in the JWT uses the "tableau" value. This value is case sensitive. • The 'aud' (Audience) and 'sub' (Subject) are included in the JWT.
10085	COULD_NOT_FETCH_JWT_KEYS	JWT could not find keys	Could not find the secret. To resolve this issue, verify the correct 'kid' (Secret ID) is used in the JWT header.
10087	BLOCKLISTED_JWS_ALGORITHM_USED_TO_SIGN	Issue with the JWT signing algorithm	To resolve the issue, you can remove the signing algorithm. For more information, see viz-portal.oauth.external_authorization_server.blocklisted_jws_algorithms .
10089	CONNECTED_APP_NOT_FOUND	Could not find connected app	To resolve this issue, ensure the issuer is calling the correct connected app ID (also known as the client ID).

10090	CONNECTED_APP_DISABLED	Connected app is disabled	The connected app used to verify trust is disabled. To resolve this issue, enable the connected app.
10091	JTI_ALREADY_USED	Unique JWT required	The JWT has already been used in the authentication process. To resolve this issue, a new JWT must be generated.
10092	NOT_IN_DOMAIN_ALLOW_LIST	Domain of the embedded content is not specified	To resolve this issue, ensure the <code>unrestrictedEmbedding</code> setting is set to <code>true</code> or <code>domainAllowlist</code> parameter includes the domains where Tableau content is embedded using the Update Embedding Settings for Site method in the Tableau REST API.
10094	MISSING_REQUIRED_JTI	Missing JWT ID	To resolve this issue, verify the 'jti' (JWT ID) is included in the JWT.
10096	JWT_EXPIRATION_EXCEEDS_CONFIGURED_EXPIRATION_PERIOD	Issue with expiration time	The 'exp' (Expiration Time) exceeds the default maximum validity period. To resolve this issue, review registered claims required for a valid JWT and ensure the correct value is used. To change the maximum validity period, you can use the <code>viz-portal.oauth.external_authorization_server.max_expiration_period_in_minutes</code> command.
10097	SCOPES_MALFORMED	Issues with scopes claim	This error can occur when the 'scp' (Scope) claim is either missing from the JWT or not passed as a list type. To resolve this issue,

			verify 'scp' is included in the JWT and passed as a list type. For troubleshooting help with a JWT, see Debugger on the auth0 site.
10098	JWT_UNSIGNED_OR_ENCRYPTED	JWT is unsigned or encrypted	Tableau does not support an unsigned or encrypted JWT.
10099	SCOPES_MISSING_IN_JWT	Missing scopes claim	The JWT is missing the required 'scp' (scope) claim. To resolve this issue, verify 'scp' is included in the JWT. For troubleshooting help with a JWT, see Debugger on the auth0 site.
10100	JTI_PERSISTENCE_FAILED	Unexpected JWT ID error	There was an unexpected 'jti' (JWT ID) error. To resolve this issue, a new JWT with a new 'jti' must be generated.
10103	JWT_MAX_SIZE_EXCEEDED	JWT exceeds maximum size	This error can occur when JWT size exceeds 8000 bytes. To resolve this issue, make sure that only the necessary claims are being passed to Tableau Server.
10105	ORIGIN_HEADER_NOT_A_VALID_URI	Invalid Origin header	This error can occur because 1) a URL is specified in the domain allowlist and 2) the Origin header does not contain a valid URL.

Register EAS to Enable SSO for Embedded Content

As a Tableau Server admin, you can register an external authorization server (EAS) to establish a trust relationship between your Tableau Server and the EAS using the OAuth 2.0 standard protocol. By establishing a trust relationship, you're able to:

- Provide your users a single sign-on (SSO) experience to Tableau content embedded in your external applications through the identity provider (IdP) you've already configured for Tableau Server
- Programmatically authorize access to the Tableau REST API (and the Metadata API starting in Tableau Server October 2023) on users' behalf using a JSON Web Token (JWT)

When embedded Tableau content is loaded in your external application, a standard OAuth flow is used. After users successfully sign in to the IdP, they are then automatically signed in to Tableau Server. Follow the steps described below to register your EAS with Tableau Server.

Important:

- Some of the procedures in this topic require configuration with third party software and services. We've made a best effort to verify the procedures to enable the EAS feature on Tableau Server. However, third-party software and services might change or your organization might differ. If you encounter issues, refer to your third-party documentation for authoritative configuration details and support.
- To enable embedding through EAS, Tableau Server must be configured to use SSL for HTTP traffic.
- In order for the session token to be valid, the clocks of the external application and the server that hosts the external application must be set to Coordinated Universal Time (UTC). If either clock uses a different standard, the connected app will not be trusted.

Step 1: Before you begin

To register an EAS with Tableau Server , you must have an EAS already configured. In addition, the EAS must send a valid JSON Web Token (JWT) that contains the registered claims and header listed in the table below.

Claim	Name	Description or required value
"kid"	Key ID	Required (in header). A unique key identifier from the identity provider.
"iss"	Issuer	Required (in header or as a claim). Unique issuer URI that identifies the trusted connect app and its signing key.
"alg"	Algorithm	Required (in header). JWT signing algorithm. Supported

		algorithm names are listed in the Class JWSSAlgorithm page in the javadoc.io documentation. The signing algorithm can be configured using the viz-portal.oauth.external_authorization_server.blocklisted_jws_algorithms command.
"sub"	Subject	User name of the authenticated Tableau Server user.
"aud"	Audience	Value must be: "tableau"
"exp"	Expiration Time	A valid JWT must not be expired. The expiration time (in UTC) of the JWT must be within the configured maximum validity period. Maximum validity period can be configured using vizportal.oauth.external_authorization_server.max_expiration_period_in_minutes command.
"jti"	JWT ID	The JWT ID claim provides a unique identifier for the JWT and is case sensitive.
"scp"	Scope	<p>For <i>embedding workflows</i>, supported values include:</p> <p>"tableau:views:embed"</p> <p>"tableau:views:embed_authoring" (Added in Tableau Server 2022.3)</p> <p>"tableau:metrics:embed" (Retired in Tableau Server 2023.3)</p> <p>"tableau:ask_data:embed" (Added in Tableau Server version 2023.1)</p> <p>Notes:</p> <ul style="list-style-type: none"> • Values must be passed as a list type. • For <code>tableau:views:embed</code>, the scope respects users' permissions already configured in Tableau Server and allows users to interact with the tools in the embedded view if available in the original view. • We recommend the embed code exclude the toolbar parameter. For more information see Known

		<p>issues (embedding workflows only) below.</p> <p>For <i>REST API authorization workflows</i>, see REST API methods that support JWT authorization.</p> <p>For <i>Metadata API workflows that use the REST API for authentication</i>, the only supported scope is <code>tableau-content:read</code>.</p>
--	--	--

Note: The JWT claims above are documented in the [Registered Claim Names](#) section in the documentation distributed by the Internet Engineering Task Force (IETF) organization.

Step 2: Register your EAS with Tableau Server

By registering your EAS with Tableau Server, you establish a trust relationship between the EAS and Tableau Server. This means when users access Tableau content embedded in your external application, they are redirected to authenticate with the IdP. The EAS generates the authentication token, which is passed to Tableau Server for verification. After the trust relationship is verified, access to the embedded content is granted users.

After registering the EAS, the trust established trust relationship applies to all sites on Tableau Server.

Note: Some EAS support the option to display a consent dialog that asks for users' approval for the application to access Tableau content. To ensure the best experience for your users, we recommend you configure your EAS to automatically consent to the external application's request on users' behalf.

Use the TSM web interface

1. As a Tableau Server admin, sign in to the Tableau Services Manager (TSM) web UI. For more information, see [Sign in to Tableau Services Manager Web UI](#).
2. Navigate to User Identity & Access > Authorization Server, and do the following:
 - a. Select the **Enable OAuth access for embedded content** check box.
 - b. In the **Issuer URL** text box, paste the issuer URL of the EAS.

- c. Click the **Save Pending Changes** button.

User Identity & Access
Configure user access to Tableau Server and manage user identities. [Learn more](#)

Identity Store Authentication Method Trusted Authentication **Authorization Server**

Register External Authorization Server
Establish trusted relationship with an external authorization server. [Learn more](#)

☒ Enable OAuth access for embedded content

☒ Server-wide trust

Enter information about the external authorization server that will generate the access token.

Issuer URL

JWKS URI

3. When finished, do the following:
 - a. In the upper-right corner of the page, click the **Pending Changes** button.
 - b. In the bottom-right corner of the page, click the **Apply Changes and Restart**

button to stop and restart Tableau Server.

Use the TSM CLI

1. Open a command prompt as an admin on the initial node (where TSM is installed) in the cluster.
2. Run the following commands:

```
tsm configuration set -k vizportal.oauth.external_author-  
ization.enabled -v true  
tsm configuration set -k vizportal.oauth.external_author-  
ization_server.issuer -v "<issuer_url_of_EAS>"  
tsm restart
```

Step 3: Next steps

For embedding workflows

After configuring Tableau Server to use your EAS, you must add embed code to your external application. Ensure that you include the valid JWT generated by your EAS, as described in Step 1, in the web component that your external application calls.

For more information about embedding Tableau content, see one or both of the following:

- Embed metrics, see [Embed Metrics into Webpages](#) topic in the Tableau Help. (In Tableau Server 2023.3, Tableau retired the ability to embed metrics.)
- Embed Tableau views and metrics using the [Tableau Embedding API v3](#).

Note: For users to successfully authenticate when they access embedded content, browsers must be configured to allow third-party cookies.

For REST API authorization workflows

After the JWT has been configured, you must add the valid JWT to the REST API Sign In request for authorized access. For more information, see [Access Scopes for Connected Apps](#).

For Metadata API workflows

After the JWT has been configured, you must add the valid JWT to the REST API Sign In request. For more information, see [Access Scopes for Connected Apps](#).

Known issues (embedding workflows only)

There are a couple of known issues when using connected apps that will be addressed in a future release.

- **Toolbar features:** When embedded content has the toolbar parameter defined, not all toolbar features will work. To work around this issue, we recommend you hide the toolbar parameter like in the example below.

```
<tableau-viz id='tab-viz' src='https://<your_server>/t/<your_
site>/...'
      toolbar='hidden'>
</tableau-viz>
```

- **Published data sources:** Published data sources set to **Prompt User** for database credentials will not display. To work around this issue, if possible, we recommend data source owners embed their database credentials instead.

Troubleshoot

When embedded content fails to display in your external application or Tableau REST API authorization fails, you can use a browser's developer tools to inspect and identify error codes that might be associated with the EAS feature enabled Tableau Server .

Refer to the table below to review the description of the error code and potential resolution.

Error code	Summary	Description	Potential resolution or explanation
5	SYSTEM_USER_NOT_FOUND	Tableau user could not be found	To resolve this issue, verify the 'sub' (Subject) claim value in the JWT is "username" for the authenticated Tableau Server. This value is case sensitive.
16	LOGIN_FAILED	Login failed	<p>This error is typically caused by one of the following claim issues in the JWT:</p> <ul style="list-style-type: none"> The 'exp' (Expiration Time) exceeds the default maximum validity period. To resolve this issue, review registered claims required for a valid JWT and ensure the correct value is used. To change the maximum validity period, you can use the viz-portal.oauth.external_authorization_server.max_expiration_period_in_minutes command.

			<ul style="list-style-type: none"> The 'sub' (Subject) is calling an unknown user. To resolve this issue, verify the 'sub' claim is "user-name". This value is case sensitive.
67	FEATURE_NOT_ENABLED	On-demand access is not supported	On-demand access is available through licensed Tableau Cloud sites only.
10081	COULD_NOT_RETRIEVE_IDP_METADATA	Missing EAS metadata endpoint	To resolve this issue, verify the EAS is configured correctly and the correct issuer is being called.
10082	AUTHORIZATION_SERVER_ISSUER_NOT_SPECIFIED	Missing issuer	To resolve this issue, verify the correct issuer is being called. To change the issuer URL, you can use the viz-portal.oauth.external_authorization_server.issuer command.
10083	BAD_JWT	JWT header contains issues	The 'kid' (Secret ID) or 'clientId' (Issuer) claims are missing from the JWT header. To resolve this issue, ensure this information is included.
10084	JWT_PARSE_ERROR	JWT contains issues	<p>To resolve this issue, verify the following:</p> <ul style="list-style-type: none"> The 'aud' (Audience) value referenced in the JWT uses the "tableau" value. This value is case sensitive.

			<ul style="list-style-type: none"> The 'aud' (Audience) and 'sub' (Subject) are included in the JWT.
10085	COULD_NOT_FETCH_JWT_KEYS	JWT could not find keys	<p>Could not find the secret.</p> <p>To resolve this issue, verify the correct issuer is being called.</p> <p>To change the issuer URL, you can use the viz-portal.oauth.external_authorization_server.issuer command.</p>
10087	BLOCKLISTED_JWS_ALGORITHM_USED_TO_SIGN	Issue with the JWT signing algorithm	<p>To resolve the issue, you can remove the signing algorithm.</p> <p>For more information, see viz-portal.oauth.external_authorization_server.blocklisted_jws_algorithms.</p>
10088	RSA_KEY_SIZE_INVALID	Issue with JWT signing requirements	<p>To resolve this issue, verify with the EAS or IdP the JWT is being signed with an RSA key size of 2048.</p>
10091	JTI_ALREADY_USED	Unique JWT required	<p>The JWT has already been used in the authentication process. To resolve this issue, the EAS or IdP must generate a new JWT.</p>
10092	NOT_IN_DOMAIN_ALLOW_LIST	Domain of the embedded content is not specified	<p>To resolve this issue, ensure the <code>unrestrictedEmbedding</code> setting is set to <code>true</code> or <code>domainAllowlist</code> parameter includes</p>

			the domains where Tableau content is embedded using the Update Embedding Settings for Site method in the Tableau REST API.
10094	MISSING_ REQUIRED_JTI	Missing JWT ID	To resolve this issue, verify the 'jti' (JWT ID) is included in the JWT.
10096	JWT_ EXPIRATION_ EXCEEDS_ CONFIGURED_ EXPIRATION_ PERIOD		The 'exp' (Expiration Time) exceeds the default maximum validity period. To resolve this issue, review registered claims required for a valid JWT and ensure the correct value is used. To change the maximum validity period, you can use the vizportal.oauth.external_authorization_server.max_expiration_period_in_minutes command.
10097	SCOPES_ MALFORMED	Issues with scopes claim	This error can occur when the 'scp' (Scope) claim is either missing from the JWT or not passed as a list type. To resolve this issue, verify 'scp' is included in the JWT and passed as a list type. For troubleshooting help with a JWT, see Debugger on the auth0 site.
10098	JWT_UNSIGNED_ OR_ENCRYPTED	JWT is unsigned or encrypted	Tableau does not support an unsigned or encrypted JWT.

10099	SCOPES_ MISSING_IN_JWT	Missing scopes claim	The JWT is missing the required 'scp' (Scope) claim. To resolve this issue, verify 'scp' is included in the JWT. For troubleshooting help with a JWT, see Debugger on the auth0 site.
10100	JTI_ PERSISTENCE_ FAILED	Unexpected JWT ID error	There was an unexpected error with the 'jti' (JWT ID). To resolve this issue, a new JWT with a new 'jti' must be generated.
10103	JWT_MAX_SIZE_ EXCEEDED	JWT exceeds maximum size	This error can occur when JWT size exceeds 8000 bytes. To resolve this issue, make sure that only the necessary claims are being passed to Tableau Server.

Data Connection Authentication

You can configure data connection authentication using Kerberos, OAuth, and single sign-on.

More information

- [Setting an Oracle Connection to Use TNSNames.ora or LDAP.ora](#) (Tableau Support)

Enable Kerberos Delegation

Kerberos delegation enables Tableau Server to use the Kerberos credentials of the viewer of a workbook or view to execute a query on behalf of the viewer. This is useful in the following situations:

- You need to know who is accessing the data (the viewer's name will appear in the access logs for the data source).
- Your data source has row-level security, where different users have access to different rows.

Supported data sources

Tableau supports Kerberos delegation with the following data sources:

- Cloudera: Hive/Impala
- Denodo
- Hortonworks
- MSAS
- Oracle
- PostgreSQL
- Spark
- SQL Server
- Teradata
- Vertica
- TIBCO

Requirements

Kerberos delegation requires Active Directory.

- The Tableau Server **identity store** must be configured to use Active Directory.
- The computer where Tableau Server is installed must be joined to the Active Directory domain.
- MIT Kerberos KDC is not supported.
- A domain account must be configured as the Run As service account on Tableau Server. See [Change the Run As Service Account](#). If your users are in a different Active Directory domain than Tableau Server and the data source, then domain trust must be configured. See [Domain Trust Requirements for Active Directory Deployments](#).
- Delegation configured. Grant delegation rights for the Run As service account to the target database Service Principal Names (SPNs). The Run As service account is delegated authority to access resources on behalf of the initiating source user.

- If you are configuring delegation on Tableau Server 2020.2 or later with an Oracle data source using a JDBC-based connector, see [Enable Kerberos Delegation for JDBC Connectors](#). Starting in Tableau 2020.2, the Oracle connector uses JDBC.

Web authoring and user Kerberos authentication

When configuring Connect to Data for a given target, you may select Integrated or Windows authentication as the preferred authentication method. However, for web authoring scenarios, the default behavior will be to use the Kerberos service account (“Run As” account) instead.

To enable user credentials in web authoring scenarios with Kerberos delegation, you must make an additional configuration using TSM. Run the following commands:

```
tsm configuration set -k native_api.WebAuthoringAuthModeKerberosDelegation -v true  
  
tsm pending-changes apply
```

After making this configuration, Kerberos Delegation becomes the default operation when selecting integrated authentication with web authoring. However, this setting will not prevent content creators from accessing the service account. Creators can still publish content that connects with the Run As service account, using Tableau Desktop or other methods.

For more information on Run As service account, see [Data Access with the Run As Service Account](#).

Configuration process

This section provides an example of the process to enable Kerberos delegation. The scenario also includes example names to help describe the relationships between the configuration elements.

1. On all nodes in Tableau Server, configure the Run As User to act as part of the operating system. For more information, see [Enable Run As Service Account to Act as the Operating System](#).

2. Tableau Server will need a Kerberos service ticket to delegate on behalf of the user that is initiating the call to the database. You must create a domain account that will be used to delegate to the given database. This account is referred to as the Run As service account. In this topic, the example user configured as the delegation/Run As account is `tabsrv@example.com`.

The account must be configured with Active Directory User and Computers on a Windows Server that is connected to the user domain:

- Open the **Properties** page for the Run As service account, click the **Delegation** tab and select **Trust this user for delegation to specified services only** and **Use any authentication protocol**.

3. Run the following TSM command to enable Kerberos delegation:

```
tsm configuration set -k wgserver.delegation.enabled -v true
```

4. Run the following TSM command apply the changes to Tableau Server:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

5. (Optional) Configure Tableau Server to use MIT Kerberos principal format.

By default, Tableau Server generates Kerberos principals using the Active Directory short name. For example, if Tableau Server performs Kerberos delegation for a user in `EXAMPLE.COM`, with a short name `EXAMPLE`, then the principal name will be: `user-@example.`

If your database is running on Linux, you may need to adjust the `auth_to_local` mapping in `krb5.conf`. For information about editing the `krb5.conf` file, see [Kerberos delegation multi-domain configuration](#). Alternatively, you can configure Tableau Server to use the full domain name for Kerberos principals by running the following commands:

```
tsm configuration set -k native_api.protocol_transition_a_d_
short_domain -v false --force-keys
tsm configuration set -k native_api.protocol_transition_upper-
case_realm -v true --force-keys
tsm pending-changes apply
```

6. Enable delegation for data connections:

- **SQL Server**—See [Enabling Kerberos Delegation for SQL Server](#) in the Tableau Community.
- **MSAS**—See [Enabling Kerberos Delegation for MSAS](#) in the Tableau Community.
- **PostgreSQL**—See [Enabling Kerberos Delegation for PostgreSQL](#) in the Tableau Community.
- **Teradata**—See [Enabling Kerberos Delegation for Teradata](#) in the Tableau Community.
- **Oracle**—See [Enable Kerberos Delegation for Oracle](#) in the Tableau Community.
- **Cloudera**—See [Enable Kerberos Delegation for Hive/Impala](#) in the Tableau Community.
- **Vertica**—See [Enabling Kerberos Delegation for Vertica](#) in the Tableau Community.
- **TIBCO**—See [Section 4, Kerberos SSO Configuration for TDV on Windows](#) in the TIBCO Professional Services guide, *TDV Integration with Kerberos*.

[Troubleshoot Kerberos](#)

[Enable Kerberos Delegation for JDBC Connectors](#)

As of version 2020.2, Tableau Server supports Kerberos delegation for JDBC connectors.

Kerberos delegation enables Tableau Server to use the Kerberos credentials of the viewer of a workbook or view to execute a query on behalf of the viewer. This is useful in the following situations:

- You need to know who is accessing the data (the viewer's name will appear in the access logs for the data source).
- Your data source has row-level security, where different users have access to different rows.

Supported data sources

Tableau supports JDBC Kerberos RunAs authentication with the following data sources:

- Oracle
- PostgreSQL

If you are configuring delegation with an Oracle data source using a JDBC-based connector, then follow the procedure in this topic. Alternatively, if the connector you are running on Tableau Server uses a native driver, then follow the procedure in the help topic, [Enable Kerberos Delegation](#).

Requirements

Kerberos delegation requires Active Directory.

- The Tableau Server information store must be configured to use LDAP - Active Directory.

- MIT KDC is not supported.

Note: You do not need to enable the Run As account to act as the operating system.

Configuration process

This section provides an example of the process to enable Kerberos delegation.

1. Tableau Server will need a Kerberos service ticket to delegate on behalf of the user that is initiating the call to the database. You must create a domain account that will be used to delegate to the given database. This account is referred to as the Run As service account. In this topic, the example user configured as the Run As account is `tab-srv@EXAMPLE.COM`.

The account must be configured for delegation in Active Directory:

- a. On a Windows Server that is connected to the user domain, open Active Directory Users and Computers.
 - b. On the **Properties** page for the Run As service account, click the **Delegation** tab and select **Trust this user for delegation to specified services only** and **Use any authentication protocol**.
2. Create a keytab file for the Run As service account.

This following example uses the `ktab` tool that is provided with the JDK . You can download the tool at [AdoptOpenJDK](#). When using `ktab` to create the keytab, use a logon principal in UPN format (for example, `service@EXAMPLE.COM`), and not a service principal name (for example, `HTTP/service.example.com@EXAMPLE.COM`). You may also generate keytabs with the `ktpass` utility, in which case you can use either style of principal name.

```
<JDK_HOME>/bin/ktab -k E:/tmp/tabsrv.keytab -a tab-srv@EXAMPLE.COM
```

Tableau Server will use the Run As service account and the associated keytab to authenticate and make a direct connection to the database.

3. Copy the keytab into the Tableau Server data directory and verify that the Run As service account can access and read the keytab file. By default the Tableau Server data directory is at `C:\ProgramData\Tableau`. If you are running Tableau Server in a distributed deployment, perform this step on each node in the cluster.
4. Create a `krb5.conf` file, and install in `C:\Windows` on all Tableau Server nodes.

If you already have a `krb5.ini` file deployed on computers in your organization, copy that file and use it for Tableau Server. For more information, see the MIT Kerberos Documentation topic, [krb5.conf](#).

To change the location of Kerberos configuration file run the following TSM command:

```
tsm configuration set -k native_api.kerberos_config_path --
force-keys -v "C:\temp\krb5.ini"
```

The following is an example of a `krb5.conf` file. Tableau Support cannot assist with creating `krb5.conf`.

```
[libdefaults]
forwardable = true
default_realm = EXAMPLE.COM
default_tkt_enctypes = rc4-hmac
default_tgs_enctypes = rc4-hmac

[realms]
EXAMPLE.COM = {
kdc = kdc.example.com
admin_server = kdc.example.com
}

[domain_realm]
```

```
.example.com = EXAMPLE.COM  
example.com = EXAMPLE.COM
```

5. Run the following TSM commands to enable Kerberos delegation, set the delegation service account, and associate the keytab file with the service account:

```
tsm configuration set -k wgserver.delegation.enabled -v true  
tsm configuration set -k native_api.datasources_impersonation_  
runas_principal -v tabsrv@EXAMPLE.COM  
tsm configuration set -k native_api.datasources_impersonation_  
runas_keytab_path -v <path-to-file>kerberos.keytab  
tsm configuration set -k native_api.protocol_transition_a_d_  
short_domain -v false  
tsm configuration set -k native_api.protocol_transition_upper-  
case_realm -v true
```

In some cases, TSM may return an error mentioning `--force-keys`. If you get this error, run the command again with the `--force-keys` parameter appended to the argument.

6. Run the following TSM command apply the changes to Tableau Server:

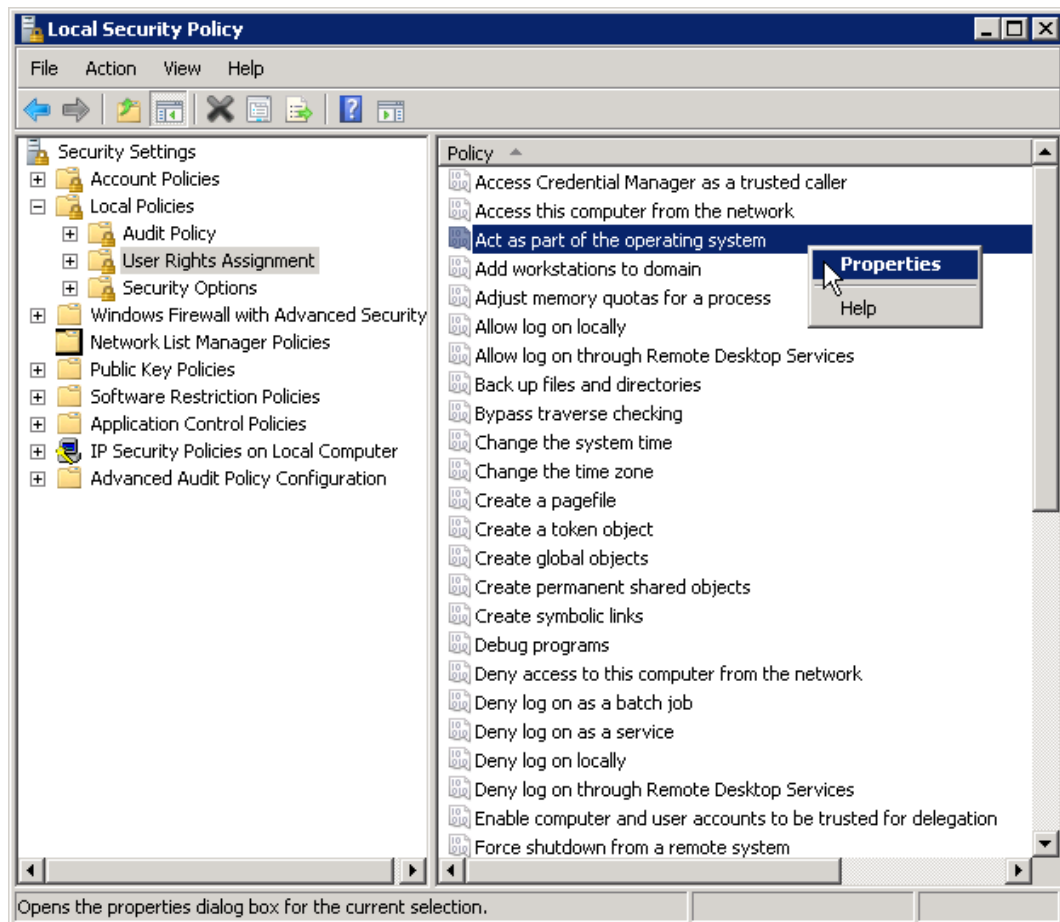

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Enable Run As Service Account to Act as the Operating System

To use Kerberos delegation with Tableau Server, you must configure the Run As service account account to act as the operating system on each Tableau Server node.

1. On the computer that is running Tableau Server, select **Start > Control Panel > Administrative Tools > Local Security Policy**.
2. In the Local Security Settings window, expand **Local Policies**, click **User Rights Assignments**, and then right-click **Act as part of the operating system** and select **Properties**.

3. In the Act as part of the operating system Properties window, click **Add User or Group**.
4. Type the <domain>\<username> for the Tableau Server Run As service account (for example: MYCOMPANY\tableau_server), and then click **Check Names**.
5. When the account resolves correctly, it is underlined. Click **OK**.

6. Click **OK** to close the Local Security Policy windows.

Enable Kerberos Run As Authentication for JDBC Connectors

As of version 2020.2, Tableau Server supports Kerberos authentication for JDBC connectors.

You can configure Tableau Server to use a Kerberos service account to access a database. In this scenario, Tableau Server connects to databases with a service account, also referred to as a "Run As service account". This scenario is referred to as "Run As authentication"

See [Run As Service Account](#).

To use Run As authentication on Tableau Server you must first create a workbook or data-source in Tableau Desktop that uses integrated authentication. When you publish to Tableau Server you will get the option to use Run As authentication. When creating a datasource with Web Authoring, Run As authentication is the default operation if you select integrated authentication.

Supported data sources

Tableau supports JDBC Kerberos delegation with the following data sources:

- Oracle
- PostgreSQL

If you are configuring Run As authentication for an Oracle data source using a JDBC-based connector, then follow the procedure in this topic. Alternatively, if the connector you are running on Tableau Server uses a native driver, you do not have to follow the steps in this topic. Instead, follow the steps to create a Run As service account as documented in the topic, [Change the Run As Service Account](#).

Requirements

Kerberos delegation requires Active Directory.

- The Tableau Server information store must be configured to use LDAP - Active Directory.
- MIT KDC is not supported.

Configuration process

This section provides an example of the process to enable Kerberos RunAs authentication.

1. Create a keytab file for the Run As service account.

This following example uses the ktab tool that is provided with the JDK . You can download the tool at [AdoptOpenJDK](#). When using ktab to create the keytab, use a logon principal in UPN format (for example, `service@EXAMPLE.COM`), and not a service principal name (for example, `HTTP/service.example.com@EXAMPLE.COM`). You may also generate keytabs with the ktpass utility, in which case you can use either style of principal name.

```
<JDK_HOME>/bin/ktab -k E:/tmp/tabsrv.keytab -a tabsrv@EXAMPLE.COM
```

Tableau Server will use the Run As service account and the associated keytab to authenticate and make a direct connection to the database.

2. Copy the keytab into the Tableau Server data directory and verify that the Run As service account can access and read the keytab file. By default the Tableau Server data directory is at `C:\ProgramData\Tableau`. If you are running Tableau Server in a distributed deployment, perform this step on each node in the cluster.
3. Run the following TSM commands to set the Run As service account and the path to the keytab file:

```
tsm configuration set -k native_api.datasources_runas_principal -v tabsrv@EXAMPLE.COM
tsm configuration set -k native_api.datasources_runas_keytab_path -v <path-to-file>kerberos.keytab
```

In some cases, TSM may return an error mentioning `--force-keys`. If you get this error, run the command again with the `--force-keys` parameter appended to the argument.

4. Create a `krb5.conf` file, and install in `C:\Windows` on all Tableau Server nodes.

Tableau Server on Windows Help

If you already have a `krb5.ini` file deployed on computers in your organization, copy that file and use it for Tableau Server. For more information, see the MIT Kerberos Documentation topic, [krb5.conf](#).

To change the location of Kerberos configuration file run the following TSM command:

```
tsm configuration set -k native_api.kerberos_config_path --  
force-keys -v "C:\temp\krb5.ini"
```

The following is an example of a `krb5.conf` file. Tableau Support cannot assist with creating `krb5.conf`.

```
[libdefaults]  
forwardable = true  
default_realm = EXAMPLE.COM  
default_tkt_enctypes = rc4-hmac  
default_tgs_enctypes = rc4-hmac  
  
[realms]  
EXAMPLE.COM = {  
    kdc = kdc.example.com  
    admin_server = kdc.example.com  
}  
  
[domain_realm]  
.example.com = EXAMPLE.COM  
example.com = EXAMPLE.COM
```

5. Run the following TSM command apply the changes to Tableau Server:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart

behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

OAuth Connections

Tableau Server supports OAuth for a number of different connectors. In many cases, OAuth functionality does not require additional configuration on Tableau Server.

From Tableau, when users sign in to data with a connector that uses OAuth, users are redirected to the authentication provider's sign-in page. After user provide their credentials and authorize Tableau to access their data, the authentication provider sends Tableau an **access token** that uniquely identifies Tableau and the users. This access token is used to access data on users' behalf. For more information, see Overview of the OAuth process below.

Using OAuth-based connections provides the following benefits:

- **Security:** Your database credentials are never known to or stored in Tableau Server, and the access token can be used only by Tableau on behalf of users.
- **Convenience:** Instead of having to embed your data source ID and password in multiple places, you can use the token provided for a particular data provider for all published workbooks and data sources that access that data provider.

Note: For live connections to Google BigQuery data, each workbook viewer can have a unique access token that identifies the user, rather than sharing a single user name and password credential.

Overview of the OAuth process

The following steps describe a workflow in the Tableau environment that calls the OAuth process.

1. A user takes an action that requires access to a cloud-based data source.

For example, you open a workbook that's published to Tableau Server.

Tableau Server on Windows Help

2. Tableau directs the user to the cloud data provider's sign-in page. The information that is sent to the data provider identifies Tableau as the requesting site.
3. When the user signs in to the data, the provider prompts the user to confirm their authorization for Tableau Server to access the data.
4. Upon the user's confirmation, the data provider sends an access token back to Tableau Server.
5. Tableau Server presents the workbook and data to the user.

The following user workflows can use the OAuth process:

- Creating a workbook and connecting to the data source from Tableau Desktop or from Tableau Server.
- Publishing a data source from Tableau Desktop.
- Signing in to Tableau Server from an approved *client*, such as Tableau Mobile or Tableau Desktop.

Default saved credential connectors

Saved credentials refers to the functionality where Tableau Server stores user tokens for OAuth connections. This allows users to save their OAuth credentials to their user profile on Tableau Server. After they have saved the credentials, they will not be prompted when they subsequently publish, edit, or refresh when accessing the connector.

Note: When editing Tableau Prep flows on the web, you may still be prompted to re-authenticate.

The following connectors use saved credentials by default and do not require additional configuration on Tableau Server.

- Anaplan
- Box
- Dropbox
- Esri ArcGIS Server
- Google Ads, Google Drive
- LinkedIn Sales Navigator
- Marketo
- OneDrive (Additional configuration is required starting with 2022.3)
- Oracle Eloqua
- ServiceNow ITSM
- Snowflake - To use "private link" requires additional configuration. For more information, see [Configure Snowflake OAuth for Partner Applications](#) on the Snowflake website and Change Snowflake OAuth to Saved Credentials.

The following connectors can use saved credentials with additional configuration by the server administrator.

- Azure Data Lake Storage Gen2, Azure Synapse, Azure SQL Database, Databricks

For more information, see [Configure Azure AD for OAuth and Modern Authentication](#).
 - Dremio

For more information, see [Set Up OAuth for Dremio](#).
 - Google Analytics, Google BigQuery, Google Sheets (deprecated in Tableau version 2022.1)

For more information, see [Set up OAuth for Google](#).
 - Intuit QuickBooks Online

For more information, see [Set Up OAuth for Intuit QuickBooks Online](#).
- OneDrive (Starting with 2022.3)

For more information, see [Configure Custom OAuth for a site](#)

- Salesforce

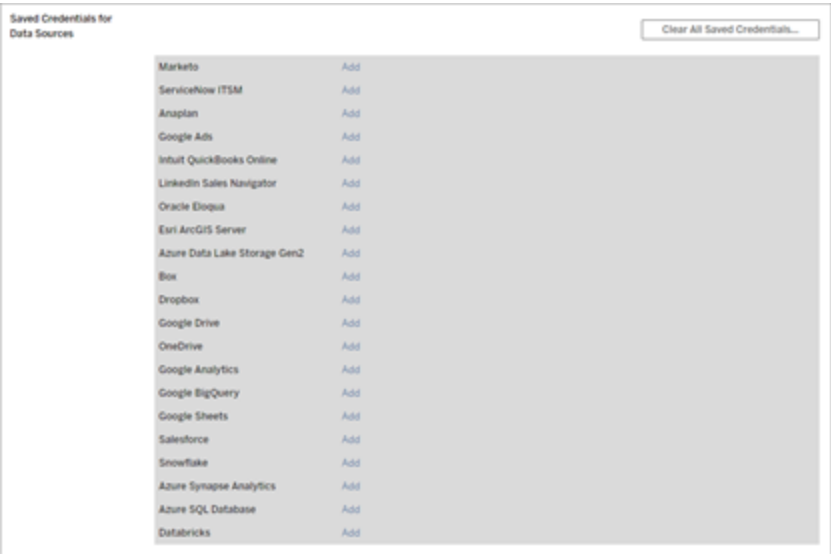

For more information, see [Change Salesforce.com OAuth to Saved Credentials](#).

- Salesforce CPD

Fore more information, see [Connect Tableau Server to the Salesforce Data Cloud](#).

Note: If Tableau Server isn't listed in the Accessed Apps list in the Google admin console, you can manually add a new app to the list using it's client ID. To create a client ID, see [Change Google OAuth to Saved Credentials](#).

All supported connectors are listed under **Saved Credentials for Data Sources** on users' **My Account Settings** page on Tableau Server. Users manage their saved credentials for each connector.

Access tokens for data connections

You can embed credentials based on access tokens with data connections, to enable direct access after the initial authentication process. An access token is valid until a Tableau Server user deletes it, or the data provider revokes it.
